69482 <ABSTRACT>This work contains an up to date list of all the Jurassic species of scleractinia in the world. It is an objective (unrevised) catalogue where every species is located in alphabetical order, in the different genera in which they have been placed by various authors. For each species, symbols allow the recognition of the successive generic positions (original, transitory, present) and if need be, a junior synonymy. The age and the name of the type locality are indicated. * The check-list is followed by a substantial and useful bibliography. [book presentation]</ABSTRACT>

69493 <TITLE>Utilisation d'un système de gestion de base de données dans la détermination générique approchée des coraux jurassiques. [using a database management system in non exhaustive generic identification of Jurassic corals]</TITLE>
69494 <SOURCE>??</SOURCE>
69495 <ABSTRACT>The database is a set of 405 cards. Each card corresponds to a genus with 17 characters, the present program allows a subset corresponding to the characters selected by the user to be extracted from this database. * It runs on an IBM PC compatible micro-computer with a dBase III+ compatible program. Each card comprises 18 fields. The first one for the genus name, the 17 others for descriptive

characters. Every character-state is coded in the following way: A for an absent character, P for a present one and AP for an ambiguous case. On running, with the same codes A, P, and AP, the operator submits a combination of 17 character-states corresponding to the specimens he wants to identify. Then, the computer quickly displays or prints a list of genera. A card (or a genus) is chosen if and only if all its fields at the state A correspond to an A or an AP of the request and if all its fields at the state P correspond to a P or an AP of the request. The check-list obtained shows junior synonyms genera and old comprehensive genera. This allows the omission of non reclassified species to be avoided and this is a major advantage for a zoological group in which generic assignments fluctuate so much. The program can be optimized by adding cards and characters. It runs as a generator of artificial classifications. The hierarchy of characters, inherent to the so called natural classifications is avoided and for a group in which fundamental characters are least conspicuous, the quality of identification may only be improved.

69532 <TITLE>Comunita a Poriferi nei Calcarei Grigi delle Vette Feltrine
(Giurassico inferiore, Prealpi Bellunesi).</TITLE>
69533 <SOURCE>Annali dell'Universita di Ferrara, n.s., ser. Scienze della
Terra 3, 4: 51-81.</SOURCE>
69534 <ABSTRACT>[...] From this approach to the Porifer facies of the Lower
Jurassic, the occurrence of the following taxa have been suggested: 1)
Demospongea, subcl. Ceractinomorpha and Tetractinomorpha; 2)
Hexactinellida, ord. Lychniscosida; 3) Sclerospongea, ord.
Stromatoporida and Ceratoporellida; The taxa associations appear to
establish three kinds of Porifer communities: 1. Demospongea and
Exactinellida comm. (Calcarei del Misone, Calcarei Selciferi a Poriferi
and Malga Agnerola facies); 2. Demospongea and Sclerospongea comm.
(Calcarei Grigi of Grappa Mt.); 3. Inozoa comm. (Giallo Reale and
Calcarei Gialli). The Demospongea and Exactinellida community from the
Cherty Limestone of the Vette Feltrine could represent a Porifer
meadow, while all the others have been referred to Porifer mud mounds.
Meadows and mounds should be placed on the external platform, below
the wave base. The setting depth has not been defined. On a
sedimentological basis, the Porifer Cherty Limestones bearing the
Demospongea-Hexactinellida community (Vette Feltrine) should correspond
a hundred meter-deeps. [fragment of extensive (!) summary]</ABSTRACT>

Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and
Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???
</SOURCE>
- 69573 <ABSTRACT>Reefs from the Late Jurassic comprise various types of coral
reefs, siliceous sponge reefs and microbolite reefs. Upper Jurassic
corals had a higher ratio of heterotrophic versus autotrophic energy
uptake than modern ones, which explains their frequent occurrence in
terrigenous settings. Coral communities changed along a bathymetric
gradient but sedimentation exerted a stronger control on diversities
than bathymetry. One coral community was adapted to brackish waters.
Reefal siliceous sponge biostromes and sponge microbolite mud mounds
generally occur below the coral facies, and hexactinellid-dominated
sponge communities generally occur below a zone of mixed "lithistid
"-hexactinellid growth. This distribution mirrors differences in
nutrient conditions, with coral facies related to stable, moderately
oligotrophic to mesotrophic conditions whereas siliceous sponges could
tolerate fluctuating levels and hence may range from extremely
oligotrophic to strongly mesotrophic settings. This is due to the fact
that hexactinellid sponges can largely live on osmotrophy and "
lithistid" sponges develop deposits of living organic matter by
hosting a huge mass of bacteria. Microbolite crusts demand strongly
reduced sedimentation and are important framework contributors in many
coral and sponge reefs. Eutrophication or oxygen depletion may exclude
reef fauna, giving rise to pure microbolite reefs. Most Upper Jurassic
reefs developed in ramp settings. High-energy reefs contain little
preserved framework, whereas low-energy reefs may have excellently
preserved framework and pronounced relief whenever microbolite crusts
provided stabilization. Reefs in steepened slope settings are generally
rich in microbolites because of bypass possibilities for allochthonous
sediment. Reef rimmed shallow-water platforms did occur but only
developed on preexisting uplifts. Upper Jurassic sponge-microbolite mud
mounds grew in subhorizontal mid to outer ramp settings and reflect a
delicate equilibrium of massive and peloidal microbolite precipitation
and accumulation of allochthonous mud and fine allochems, determined by
the distance to shallow-water carbonate factories. Disturbances in this
equilibrium lead to the development of sponge biostromes or the
disappearance of sponge facies … [fragment of extensive summary]

69597 <TITLE>Upper Jurassic reef types and controlling factors.</TITLE>

69598 <SOURCE>Profil 5: 1-45.</SOURCE>

69599 <ABSTRACT>Reefs occurred widespread during the Late Jurassic, particularly along the northern Tethyan shelf and the marginal basins of the young North Atlantic Ocean. They thrived in a variety of settings such as on intrabasinal tectonic and halokinetic uplifts, within lagoons or within siliciclastic fan deltas. Most frequently they grew in homoclinal to steepened ramp settings, where they occupied a wide bathymetric field from the innermost, partly even hypohaline, part down to outer ramp settings. Compositionally they comprise the end members 'coral facies'; 'siliceous sponges facies'; and 'microbial facies'; but transitions and successions are frequent. Microbial crusts are important not only in the microbial facies where they build thrombolitic reefs up to 30 meters thick but also within the siliceous sponge and coral facies where they occur at variable quantities and are largely responsible for constructing a positive relief. 69610 <TITLE>The origin of Jurassic reefs: Current research developments and results.</TITLE>

69611 <SOURCE>Facies 31: 1-56.</SOURCE>

69612 <ABSTRACT>In order to elucidate the control of local, regional and global factors on occurrence, distribution and character of Jurassic reefs, reefal settings of Mid and Late Jurassic age from southwestern Germany, Iberia and Romania were compared in terms of their sedimentological (including diagenetic), palaeoecological, architectural, stratigraphic and sequential aspects. Upper Jurassic reefs of southern Germany are dominated by siliceous sponge - microbial cnist [??] automicritic to allomicritic mounds. During the Oxfordian these form small to large buildups, whereas during the Kimmeridgian they more frequently are but marginal parts of large grain-dominated massive buildups. Diagenesis of sponge facies is largely governed by the original composition and fabric of sediments. The latest Kimmeridgian and Tithonian spongiolite development is locally accompanied by coral facies, forming large reefs on spongiolitic topographic elevations or, more frequently, small meadows and patch reefs within bioclastic to oolitic shoal and apron sediments. New biostratigraphic results indicate a narrower time gap between Swabian

- and Franconian coral development than previously thought. Palynostratigraphy and mineralostratigraphy partly allow good stratigraphic resolution also in spongiolitic buildups, and even in dolomitised massive limestones.[part of extensive summary] </ABSTRACT>

69651 <ABSTRACT>Coral reefs are complex ecosystems. Their main producers - the corals - are more primitive organisms. Nevertheless they create complicated constructed skeletons presenting a wide range of shapes. For half a billion years exist corals, for about 250 million years the stony corals (Scleractinia) which colonize also today oceans. Changing environmental conditions forced the sensible organisms to create again and again new constructions resulting in a almost unlimited richness of forms through time. Not much is known about the relationship between the construction of the skeleton made of calcium carbonate and the biology of the living animal, mainly for groups which lived in periods long ago making classification and taxonomy difficult. This book will be help to work with Mesozoic corals (without Triassic) and gives in five large chapters (morphology; palaeoecology, diversity and evolution; sampling and examination; systematics and list of common genera; coral localities) insight in the most important aspects of a difficult organism group. The book is based on lecture material and is

- written for geology and biology students, as well for interested amateurs and biologists or geologists who want to gain insight in this invertebrate group. Much yet unpublished data on systematics, diversity and taxonomy makes the book up to date and might be interesting also for specialists. All drawn figures of the book are new; the majority of fossil thin sections has been not published before. The numerous illustrations of fossil corals have been selected from a pool of more than 4000 scanned thin sections and peels - material from the whole world, among them samples from countries as exotic as Iran, Jamaica, Japan or Tanzania. - 69729 <ABSTRACT>Investigations are based on three different depositional areas in which siliceous sponges, mainly with a rigid skeleton (hexactinellids and "lithistids") represent the prevailing faunal elements. Within these sedimentary environments different forms of sponge bioconstructions developed, which comprise bioherms, biostromes and sponge meadows. The mainly flat-shaped "lithistid " biohermal assemblage of the Kimmeridgian developed in a deeper lagoonal environment, poor in water-derived nutrients. They gained bottom-derived nutrients and / or harbored autotrophic cyanobacteria. The dominating erect hexactinellids of the other two depositional areas reflect sufficient nutrient supply in the water body. They developed in

a partly restricted (Bajocian sponge biostromes) to open-marine (Lower Campanian sponge meadows) environment. Densely populated bioherms, associated with organic crusts developed under oligotrophic conditions to guarantee appropriate nutrients and substrate for attachment. A self-regulating biotic system developed, independent of the surrounding environment. This state of self-organization was not reached by sponges of biostromes and meadows. Sponge bioconstructions developed during transgressions since nutrients are better available and provided in a fine fraction, that can be metabolized by the organisms. Furthermore, low energies were necessary for transferring sponge tissue to automicrite. Different types of automicrite, aphanitic and peloidal cements reflect differences in water energy and chemistry. Higher energies and higher pH-values correspond to peloidal automicrites, low energy and more alkaline water to aphanitic ones. This is reflected in the state of preservation of sponges and the time of dissociation of their skeletons. Geochemical analyses hint at an original low-Mg-composition of those automicrites. Sulfur, organic carbon and the DOP (degree of pyritization)-values show different paleoredoxconditions during early diagenesis in the three environments which correlate with the density of population in the bioconstructions.

69740 <TITLE>Evolution of the post-Triassic pachythecaliine corals.</TITLE>

69741 <SOURCE>Bulletin Biological Society of Washington 10: 242-256.</SOURCE>

69742 <ABSTRACT>Triassic pachythecaliines, i.e., Zardinophyllids, and primitive amphistreids, differ from the coeval scleractinians in having pachythecal wall, septa developed deeply in the calice, smooth septal faces, and two-by-two manners of the protoseptal insertion. Among Jurassic and Cretaceous corals, only amphistreids have a thick, pachythecal wall (pachythecaliine apomorphy)., whereas other supposed post-Triassic pachythecaliines, i.e., carolastreaeids, donacosmiliids, intersmiliids, and heterocoeniids, share either only some morphological characters with pachythecaliines, or their coralla are too badly preserved and no diagnostic microstructural characters are recognizable. Review of various Mesozoic taxa that previously have been linked with the pachythecaliines, i.e., agatheliids (Agathelia, Stylohelina, Bracthelina), Amphimeandra, Bodeurina, and Palaeohelia suggests that their alleged "pachythecaliine" characters are either shared with other scleractinians (trabecular perithecium of agatheliids) or not homologous with those in pachythecaliines (thick wall of Palaeohelia). Pseudoastraeopora, the only Cenozoic (Eocene) coral that originally was classified as pachythecaliid, represents, most likely some distinct acroporoid taxon. It is generally assumed that pachythecaliines become extinct at the end of the Mesozoic era, and our review based on presence/absence of apomorphic characters corroborate this hypothesis. However, we still need more arguments to falsify an alternative hypothesis that some, and a few apomorphic pachythecaliine characters could be lost in some lineages that members are thus no longer recognizable as pachythecaliine descendants.

69781 <ABSTRACT>The volume contains a list of all 2,735 localities from which Cretaceous corals were reported. Each locality is provided with data on the stratigraphy, lithostratigraphy, additional literature, and often additional notes (exact positions are omitted on request by the majority of coauthors). Each locality is complemented by a list of indicated coral species. Many countries and regions are profoundly checked by 29 local specialists from all over the world. The Catalogue

of Localities may be an interesting handbook for everybody who is working on the Cretaceous, because numerous localities are not only known to have yielded corals but also other fossil organism groups.

69857 <TITLE>Biostratigraphical dating of Cretaceous coral communities using
large data sets.</TITLE>
69858 <SOURCE>Paläontologische Zeitschrift 76, 1: 75-81.</SOURCE>
69859 <ABSTRACT>Habitats of hermatypic corals are shallow and turbulent
marine environments that often lack biostratigraphic index fossils. For
that reason many Cretaceous coral faunas are imprecisely dated or dated
only on the basis of comparisons with other coral faunas. Using a large
database on the taxonomy, stratigraphical and geographical distribution
of corals in the Cretaceous, a method is proposed that will make it
possible to specify the stratigraphical age of coral associations on
the basis of their specific composition. In this process the
stratigraphical range of the species (calculated before from well-dated
faunas) is summarized and a probable age of the association proposed.
The method does not only help to assess the biostratigraphical age of a
fauna, but may also indicate whether a fauna represents an original
composition or is a mixed association derived from reworked horizons or
olistoliths. The method can be applied to any other organism group,
provided that the essential data for a comparison are available.

69870 <TITLE>Corals and rudists in the late Cretaceous: a critique of the hypothesis of competitive displacement.</TITLE>
69871 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 225-239.</SOURCE>
69872 <ABSTRACT>The late Cretaceous saw the sessile rudist bivalves reach maxima of adaptive diversity and abundance on Tethyan carbonate platforms, yielding extensive 'rudist formations'. Meanwhile, reef frameworks built by corals were of notably limited development, although diverse associations of corals in tabular bedded units may accompany the rudist formations. * The hypothesis of competitive displacement of reef-building corals by rudists has sometimes been invoked to explain these patterns. An alternative view is that they reflect passive faunal replacement mediated by environmentally triggered extinctions, perhaps together with changes in carbonate platform ecosystems. The hypothesis of competition between contemporaneous organisms cannot be tested by looking at patterns of biotic turnover alone, as such patterns are the effects of many factors. What is needed is detailed palaeoecological analysis of co-occurrences of the postulated competitors. * The Santonian carbonate platform deposits of Sant Corneli in the southern Central Pyrenees contain abundant and diverse corals, as well as rudists. A spectrum of biotic assemblages, from coral-dominated to rudist-dominated, is found to correspond with a sedimentary facies gradient expressed both in vertical successions and in a lateral zonation. The corals and rudists largely occupied different biotopes, and even in mixed assemblages no evidence for competitive interference between neighbors (e.g. overgrowth relationships) has been detected. These observations imply little, if any, mutual interference between members of the two groups, in the occupation of space, while inferred nutritional differences between them allow us to reject trophic overlap. * Similar distributional patterns reported for other Cretaceous assemblages lead us to conclude that there was probably little or no competition between rudists and corals, so undermining the competitive displacement hypothesis. We further dispute the underlying assumption that the rudists were occupying broadly the same kinds of habitats that hosted coral reefs at other times; the rudists usually thrived on flat to gently inclined mobile sediment surfaces, which we argue would have been unfavourable sites for reef development.</ABSTRACT>

69909 <TITLE>Taxonomy, autecology and palaeobiogeography of the middle Cretaceous genus Parkeria Carpenter, 1870 (spherical hydrozoan).</TITLE>
69910 <SOURCE>Journal of Systematic Palaeontology 1, 3: 161-186.</SOURCE>
69911 <ABSTRACT>A revision of the poorly known, colonial, spherical hydrozoan genus Parkeria Carpenter 1870 and its included species is presented. Corresponding skeletal architecture and mode of accretion confirm the suggestion that the genus belongs to the family Hydractiniidae Agassiz 1862. A previous classification of Parkeria and the Late Triassic spherical hydrozoan genus Heterastridium Reuss 1865 within the family Heterastridiidae Frech 1890 was based on external morphology only. Considering the similarities of Heterastridium with representatives of the family Milleporidae Fleming 1828, the Heterastridiidae may well be redundant. Parkeria sphaerica Carter 1877, from the Late Albian / Early Cenomanian mainly of Europe, is characterised by an originally aragonitic, spherical skeleton up to 70 mm in diameter formed by concentric laminae and radiating pillars interlaced by stolonal tubes. P. cf. sphaerica from Oman lacks the concentric internal fabric and shows irregularly-formed skeletons; therefore, it is placed in the species with reservation. P. provalei Parona 1909, from the Aptian of Italy, is smaller (~20 mm), has larger skeletal interspaces and lacks the strict incremental growth of P. sphaerica. The absence of external attachment areas in Parkeria suggests a free-living mode of life. The skeletons of P. sphaerica and P. provalei testify long-term uniform centrifugal skeletal accretion. Contrary to previous assumptions, they are not interpreted as floating (i.e. planktonic) colonies but as ' benthic drifters' that were constantly carried and drifted across the sea-bottom by currents and/or waves. This mode of life, where the zooids fed on benthic microorganisms, was aided by the light-weight design of the skeletons, the cavities of which were presumably filled with gas. Estimates of skeletal-interskeletal ratios and density calculations support the existence of weak buoyancy. The genus shows a rather disjunct palaeobiogeographical distribution in shallow seas of low to warm-temperate palaeolatitudes during the Aptian and Late Albian / Early Cenomanian.</ABSTRACT>

69923 <SOURCE>Paläontologische Zeitschrift 68: 211-221.</SOURCE>
69924 <ABSTRACT>A new thecate hydroid from the Maastrichtian Chalk (Upper Maastrichtian) preserved by bioimmuration is described as Filelloides cretacea n.g. n.sp. It comprises five hydrothecae of a hydrozoan colony settling upon an algae sheet, which were overgrown by a disc-shaped cyclostome bryozoan colony of the genus Actinopora. Its basal face shows the negative relief of the throughout annulated hydrothecae which are extremely well molded in all details. Among Recent colonial Hydroida the genus Filellum Hincks of the family Lafoeidae is the nearest relative, our specimen differs from the latter in that the hydrothecae are not connated with the hydrocaulus or the hydrorhiza. Filelloides n.g. is one of the few non-mineralized Cretaceous hydrozoan genera. Their rare record in the Mesozoic contrasts with their fairly common occurrence in the Palaeozoic.</ABSTRACT>

69935 <TITLE>Morphologic und Taxonomie der Gattung Pseudopolytremacis Morycowa 1971 (Octocorallia; Kreide).</TITLE>
69936 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 211-220. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
69937 <ABSTRACT>The genus Pseudopolytremacis Morycowa, 1971 (Octocorallia) has been morphologically examined in greater detail and taxonomically revised on the basis of abundant samples from the Cenomanian layers of the Saxon Upper Cretaceous and reference material from Westphalia (Germany). It differs from the otherwise very similar Polytremacis in that there are spiniform accretions on the inner edges of the septa. The genus Proheliopora Kuzmicheva 1975 is considered to be synonymous with Pseudopolytremacis. Four species occurring in the Cretaceous (Barremian - Cenomanian of Eurasia) are assigned to this genus, one of them being described as a new species.</ABSTRACT>

69948 <TITLE>Stratigraphy of Cretaceous coral genera.</TITLE>
69949 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Abhandlungen 238: 231-277.</SOURCE>
69950 <ABSTRACT>Post-Palaeozoic coral genera are known to be long-lived.

Systematic monographs define the stratigraphic distribution of the genera in general terms such as *Jurassic*; or *Early Cretaceous*. The usefulness of the coral genera as dating aids is restricted by imprecise data concerning their stratigraphic distribution. More precise data could make it easier to date sediments that contain only corals or other organisms not really suited as index fossils. To assess the stratigraphic distribution of Cretaceous coral genera, a computer database containing records of species taken from the literature was analysed and compared with available type material in museums and university collections worldwide. Cases where the specimen data did not agree with the stratigraphic distribution of a genus reported in the literature were examined in detail and are discussed here. According to the literature a total of 705 coral genera (subclass Hexacorallia with the order Scleractinia; subclass Octocorallia with the orders Alcyonacea, Coenothecalia, and Gorgonacea) are known from the Cretaceous. Range data were determined for 394 of them. The remaining 311 genera were found to be synonyms, poorly defined, invalid, or they simply did not occur in the Cretaceous. The results of this study are restricted by the poor definition of many genera so that it was not possible to indicate their distribution because their morphological characteristics were unknown and it was not clear what species had to be assigned to them. </ABSTRACT>

69963 <ABSTRACT>The middle Cretaceous genus *Paronastraea* Beauvais 1977 is being revised on the basis of sample material available from Italy, France, Germany, and Greece. *Paronastraea*, a plocoid and cerioid coral similar to *Pachycoenia*, is characterised by regular secondary septal apophyses arranged in pairs. Six species are distinguished by their respective numbers of septal cycles and systems, two of them in open nomenclature and one, *Paronastraea occulta* from the Early Aptian of Greece, is newly described. The genus occurred from the Barremian to the basal Cenomanian in the central and eastern Tethys.</ABSTRACT>

70000 <TITLE>Catalogue of Cretaceous Corals I. Repertoire of Species.</TITLE>
70001 <SOURCE>Catalogue of Cretaceous Corals 1, 137 pp; Dresden (CPress Verlag).</SOURCE>
70002 <ABSTRACT>The Repertoire lists a total of 3,030 coral species whose type localities are - as far as is known - of a Cretaceous age and were established in the period between 1758 and 1999. The Repertoire of Species is designed on the basis of the valuable work published by Bernard Lathuiliere on the Jurassic corals (1989), but some details have been modified (thus, the authors of genera are indicated, papers published by one and the same author in the same year are more clearly distinguished). The Repertoire lists all species under the current genus and under the genus under which the species was originally established (according to the literature published before January, 1, 2000). Synonyms, both objective and subjective ones, are generally not taken into account. All species are cited, whether they are synonymous or not. Species which are described in the sense of a subsequent author and used over a long time period are indicated. Invalid species are cited according to their low number but are indicated and invalid species names are cited without correction. Also homonyms (genera and species) are cited as they are. The type locality (or region, if no exact type locality is known), lithostratigraphy and chronostratigraphy are indicated under the original genus. It is indicated as correctly as possible. In some rare cases in which several localities in various countries are indicated, no locality is cited. Where the name of the locality (or of the formation) has changed since it was first used in the literature, the old name is indicated in brackets. An index is provided which cites the generic and specific names; the specific name points to two entries when the original and current genus differ. The reference list indicates all authors of taxa cited; in a few cases where the exact source was not found, it has been omitted.</ABSTRACT>

70013 <TITLE>Scleractinian corals of the Cretaceous. A compilation of Cretaceous forms with descriptions, illustrations and remarks on their taxonomic position.</TITLE>
70014 <SOURCE>published by the author: 539 pp., 142 pls., 86 text-figs; Knoxville, Tennessee.</SOURCE>
70015 <ABSTRACT>This study is a taxonomic review of the scleractinian coral genera of the Cretaceous period. It deals with over 600 taxa, of which nearly 300 are discussed in detail. It is the first extensive compilation of Cretaceous coral genera since the Treatise works of Alloiteau (1952a, 1957) and Wells (1956). A diagnosis is provided for each genus, as well as for each higher levels taxonomic category, and issues concerning taxonomic assignments are discussed in detail. The descriptions are accompanied by illustrations (142 pls. And 86 text-figs.) of representatives of each genus and, in many cases, include illustrations of the holotype or a paratype of the type species. Also included is the first comprehensive overview of the stratigraphical and geographical ranges of each genus from Triassic to recent. A glossary and index to the genera and approximately 2200 species are provided, and the following new taxa are described: Columnocoenia elachia nom. nov., Turnsekophyllia cantabrica gen. nov., sp.nov., Rhipidastraea eliasovae sp.nov., Cycloseris (?) wellsi sp.nov., and Comoseris aptiensis sp.nov. A neotype is established for the type species of the genus Thecosmilia, Thecosmilia trichotoma (Goldfuss, 1826).</ABSTRACT>

70039 <TITLE>Morphology, taxonomy and distribution of the Cretaceous coral genus Preverastraea (Late Barremian-Cenomanian; Scleractinia).</TITLE>
70040 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 113, 1: 3-19.</SOURCE>
70041 <ABSTRACT>The Cretaceous coral genus Preverastraea is being revised, mainly on the basis of sample material. This cerioid, occasionally astreoid or phaceloid, genus is characterised by round or polygonal calices, compact septa in a regular hexamerall symmetry and lonsdaleoid septa. The wall is of the same structure as the septa. The genera Bogdanovicoenia, Paraacanthogyra, and Saxuligyra are considered synonyms of Preverastraea. Related genera are Aulastraeopora and Apoplacophyllia, which only differ by their solitary or dendroid growth forms. There are altogether 13 species of Preverastraea. The genus,

which occurred worldwide, is restricted to the period from the Late Barremian to the Late Cenomanian, being most common in the Aptian to Early Albian. Eighty-three samples are either known from the literature or have been to hand. This makes *Preverastraea* a rather rare genus.

70065 <TITLE>A Cretaceous scleractinian coral with a calcitic skeleton.</TITLE>

70066 <SOURCE>Science 318, 5847: 92–94.</SOURCE>

70067 <ABSTRACT>It has been generally thought that scleractinian corals form purely aragonitic skeletons. We show that a well-preserved fossil coral, *Coelosmilia* sp. from the Upper Cretaceous (about 70 million years ago), has preserved skeletal structural features identical to those observed in present-day scleractinians. However, the skeleton of *Coelosmilia* sp. is entirely calcitic. Its fine-scale structure and chemistry indicate that the calcite is primary and did not form from the diagenetic alteration of aragonite. This result implies that corals, like other groups of marine, calcium carbonate-producing organisms, can form skeletons of different carbonate polymorphs.</ABSTRACT>

- 70144 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 115, 1: 49-58.</SOURCE>
- 70145 <ABSTRACT>The Cretaceous species of the coral genus Diplocoenia are revised, mainly on the basis of sample material. This genus is characterised by polygonal calices in a cerioid arrangement, compact septa in a regular symmetry and a dissepimental ring with the appearance of a second inner wall. Of the 18 Cretaceous species reported in the literature, five are confirmed, four are synonyms and nine do not belong to this genus. The species with the widest geographic and stratigraphic distribution is Diplocoenia dollfusii Prever, 1909, originally described from the Monti d'Ocre complex in the Abruzzo province. The genus occurs in the Cretaceous only in the central Tethys and in the Boreal, and ranges from the Middle Jurassic to the Aptian (?Early Albian). Only about 50 samples from the Cretaceous exist or are known from the literature, making Diplocoenia rather rare in the Cretaceous. [original abstract]</ABSTRACT>

- 70157 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 116, 2: 177-188.</SOURCE>
- 70158 <ABSTRACT>The Early Cretaceous coral genus Felixigyra Prever 1909 is revised on the basis of type material from Italy. Felixigyra has a hydnochoroid-meandroid colony organisation with conical monticules attached to each other. The very thick monticules are arranged in a way that calicular centres become apparent. The septa are compact and rhopaloid. The genus can be related to other genera of the Eugyridae family, but differs from them by its particularly developed monticules. It also shows certain resemblance to meandroid genera of the family Trochoidomeandridae. Of the six species originally assigned to Felixigyra only five are recognized, since the type of Felixigyra crassa is too poorly preserved to give a diagnosis. The remaining five species have almost no significant difference in calicular dimensions. In addition to the Italian material, one sample from the Early Cenomanian of Greece and one sample from the Early Albian of Mexico are also assigned to the genus. Material assigned to Felixigyra after Prever (1909) needs to be entirely reclassified to the genus Eohydrophora. [original abstract]</ABSTRACT>

- 70171 <ABSTRACT>The Early to early Late Cretaceous coral genus Tiarasmilia wells, 1932 is revised on the basis of the type species. The solitary coral is characterised by regular septal symmetry and the abundant apophysal septa that ornament the septa pairwise. The genus is re-assigned to the family Heterocoeniidae. The genus Budaia wells, 1933 is considered to be a junior synonym of Tiarasmilia. Four Tiarasmilia species are recognised, the respective type species of Tiarasmilia and Budaia, and two as yet unnamed species for which not enough specimens were available to erect new taxa. 70197 <ABSTRACT>On the base of type material and depicted specimens, features and genera of the family Aulastraeoporidae (Order Scleractinia, suborder Heterocoeniina) are discussed. The genus Aulastraeopora Prever 1909 is described in detail and is considered to be a senior synonym of Blothrocyathus wells 1932. The known species of Aulastraeopora are briefly described. One species - A. schnauzeae from the Cenomanian of Greece - is newly described.</ABSTRACT>

70208 <TITLE>A new Early Cretaceous coral (Anthozoa; Scleractinia; Dendrophylliina) and its evolutionary significance.</TITLE>
70209 <SOURCE>Journal of Paleontology 78, 3: 501-512.</SOURCE>
70210 <ABSTRACT>A new coral, Blastozopsammia guerreroterion, from the Mid-Cretaceous (upper Albian-lower Cenomanian) Mal Paso Formation of southwestern Mexico is the earliest known and the first Mesozoic colonial member of the Dendrophylliidae, an extant worldwide group. Blastozopsammia is characterized by a ramose corallum produced by extratentacular budding, dimorphic corallites, and branches with a continuous axial corallite sheathed in an orderly arrangement of radially arrayed secondary corallites and a robust layer of reticulate coenosteum. This growth form is similar to that of many modern reef-building species of Acropora Oken, 1815 and species of a nonreefal Petrophyllia Conrad, 1855 (=Archohelia Vaughan, 1919). Based on corallite configuration, growth form and analogy with Acropora, Blastozopsammia had a relatively high degree of colony integration and may have been zooxanthellate. The combination of an axial corallite with radially arrayed secondary corallites has been regarded as one of the morphological and ecological pinnacles of coral evolution, yet it is rare among the Scleractinia. This growth form has not been recognized in any Cenozoic dendrophylliids. Blastozopsammia is an evolutionary enigma because no ancestral lineage or closely related taxon has been identified. However, the most likely origin of colonial Dendrophylliidae is Jurassic or Early Cretaceous Actinacididae. [original abstract]</ABSTRACT>

- 70223 <ABSTRACT>Late Cretaceous hippuritid and radiolitid rudists have been analyzed in sclerochronological profiles for isotopic (δ13C, δ18O) and chemical (Ca, Mg, Sr, Mn, Fe) compositions of calcitic outer shell layers. Seasonal temperature gradients of 9-12°C are recorded in shells from paleolatitudes of 20-30° N (Greece, Turkey), and no distinct annual temperature variations existed in the probably more saline surface waters of the equatorial Tethys (Oman). Annular growth rates are delineated by a distinct cyclicity in δ18O and Mg concentrations, and range from <10 mm in calm lagoonal settings to 40mm in habitats with rapidly accumulating or unstable substrata. Potential community CaCO3 productions approach the upper limit of modern coral reefs, and occurred at similar levels in calcareous and siliciclastic environments. Sedimentation rates and rudist growth fabrics are constrained by different growth rates of coexisting species.</ABSTRACT>

- 70236 <ABSTRACT>An extensive catalogue of Cretaceous sponges within the collections of the two museums in Goettingen and Hildesheim. It starts with a general introduction and provides examples of the handwritings of Schrammen, Zittel and Roemer, which has proven very useful for the identification of non-figured types. It also contains a biographical chapter of life and work of Anton Schrammen who wrote the main well-known monograph on Jurassic and Cretaceous siliceous sponges. The catalogue itself is very detailed. It is organized according to the lowermost taxonomic species or subspecies level and contains all data, when and where published, nomenclatorical status, as well as (according to the labels) locality source and stratigraphic position. On the plates a representative choice of the types are figured, and the main skeletal architectures are shown in very nice and instructive SEM-photos. A great help for everybody interested in Cretaceous siliceous sponges!</ABSTRACT>

70260 <TITLE>Extinction and recovery patterns of scleractinian corals at the Cretaceous-Tertiary boundary.</TITLE>
70261 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 214, 3: 195-223.</SOURCE>
70262 <ABSTRACT>The extinction and recovery of scleractinian corals at the Cretaceous-Tertiary (K-T) boundary was analyzed based on a global database of taxonomically revised late Campanian to Paleocene coral collections. In contrast to earlier statements, our results indicate that extinction rates of corals were only moderate in comparison to other marine invertebrates. We have calculated a 30% extinction rate for Maastrichtian coral genera occurring in more than one stratigraphic stage and more than one geographic region. Reverse rarefaction suggests that some 45% of all coral species became extinct. Photosymbiotic (zooxanthellate) corals were significantly more affected by the extinction than azooxanthellate corals; colonial forms were hit harder than solitary forms, and among colonial forms an elevated integration of corallites raised extinction risk. Abundance, as measured by the number of taxonomic occurrences, had apparently no influence on survivorship, but a wide geographic distribution significantly reduced extinction risk. As in bivalves and echinoids neither species richness within genera nor larval type had an effect on survivorship. An indistinct latitudinal gradient is visible in the extinction, but this is exclusively due to a higher proportion of extinction resistant azooxanthellate corals in higher-latitude assemblages. No significant geographic hotspot could be recognized, neither in overall extinction rates nor in the extinction of endemic clades. More clades than previously recognized passed through the K-T boundary only to become extinct within the Danian. These failed survivors were apparently limited to regions outside the Americas. Recovery as defined by the proportional increase of newly evolved genera, was more rapid for 31 zooxanthellate corals than previously assumed and less uniform geographically than the extinction. Although newly evolved Danian azooxanthellate genera were significantly more common than new zooxanthellate genera, the difference nearly disappeared by the late Paleocene suggesting a more rapid recovery of zooxanthellate corals in comparison to previous analyses. New Paleocene genera were apparently concentrated in low latitudes, suggesting that the tropics formed a source of evolutionary novelty in the recovery phase.</ABSTRACT>

70273 <TITLE>Corals of the K/T-boundary: Scleractinian corals of the Suborders Astrocoeniina, Faviina, Rhipidogyrina, and Amphistraeina.</TITLE>

- 70274 <SOURCE>Journal of Systematic Palaeontology 2006, 4: 1-108.</SOURCE>
- 70275 <ABSTRACT>This taxonomic review of the scleractinian corals of the Maastrichtian and Paleocene period focuses on the scleractinian suborders Astrocoeniina, Faviina, Rhipidogyrina and Amphistraeina. This, the first extensive compilation of coral species of the K/T (Cretaceous/Tertiary) boundary, deals with more than 2500 records of 550 nominal taxa. In addition to the re-examination and re-evaluation of described forms, this study also includes the first description of the largest Maastrichtian coral assemblage known (consisting of about 4000 specimens from Jamaica), as well as new material from the Campanian-Maastrichtian of Argentina, Lower Maastrichtian of Mexico (Cerralvo), and the Paleocene of Austria (Kambübel-Kalke). A diagnosis is provided for each species, as well as for each higher-level taxonomic category and issues concerning taxonomic assignment are discussed in detail. The descriptions are accompanied by illustrations of representatives of each species and, in many cases, include illustrations of type or original material. Also included is the first comprehensive overview of the stratigraphical and geographical ranges of each taxon. In the four suborders evaluated in this paper, 123 valid species can be reliably documented as occurring in the Maastrichtian and/or the Paleocene. The largest number of species is in the suborders Faviina and Astrocoeniina. In the Faviina 62 valid species are known from the Maastrichtian, of which 35 (56.5%) crossed the K/T-boundary, while in the Paleocene 14 new species appeared. In the Astrocoeniina 18 valid species occurred in the Maastrichtian, eight of which (44.4%) crossed the K/T-boundary and 16 new species appeared in the Paleocene. Only eight species of Rhipidogyrina and five species of Amphistraeina occurred in the Maastrichtian and although two amphistraeinid made it into the Paleocene, only one of the rhipidogyrinids crossed the K/T boundary. No new species of Amphistraeina appeared in the Paleocene. According to this revision on the genus level 44 out of the 65 genera crossed the K/T-boundary, which is 67.7% (12 genera went extinct, 9 genera have their first occurrence in the Paleocene). In comparison to previous estimates this result (generic extinction of around 32%) represents the best estimation for scleractinian corals at present and corresponds to recently reported results of other macroinvertebrate groups after taxonomic revision (e.g. echinoids).</ABSTRACT>

70325 <TITLE>Lower and Mid-Cretaceous Coralline Sponge Communities of the Boreal and Tethyan Realms in Comparison with the Modern Ones - Palaeoecological and Palaeogeographical Implications.</TITLE>
70326 <SOURCE>Proc. 3rd International Cretaceous Symposium Tuebingen 1987 [Wiedmann J. (ed.): Cretaceous of the Western Tethys]: 851-878; Schweizerbart, Stuttgart.</SOURCE>
70327 <ABSTRACT>The coralline sponges (chaetetids, stromatoporoids, sphinctozoans, pharetronids) are sponges with a rigid calcareous basal skeleton. Within modern oceans 3 communities are observed: 1. An Indopacific reef community characterized by calcified demosponges like Acanthochaetetes, Astroclera, Stromatospongia, Merlia, and pharetronid calcarean sponges (Murrayonida, Minchinellia). 2. A Mediterranean non-reefal community characterized by pharetronids (e.g. Petrobiona) and the calcified demosponge Merlia normani. 3. A Caribbean reef community characterized by ceratoporellid / agelasid calcified demosponges. From the mid-Cretaceous comparable communities are known. Non-reefal subtropical pharetronid communities are known from the Aptian of Faringdon (England) and the Cenomanian of the Essener Gruensand (West Germany). These sponge communities are characterized by sycettid sphinctozoans (Barroisia, Thalamnopena), minchinellid pharetronids (Lymnopena), and rarely by the calcified demosponge Neuropora. The Barremian / Lower Aptian coralline sponge communities from the Tethyan Realm (e.g. Helvetic " Schrätkalk") are not comparable with the modern ones. After the Middle Aptian (Gargasian) events new coralline sponge communities occurred within the North Spanish Urgonian reef platforms, e.g. the Acanthochaetetes community which has close taxonomic and ecological relationship with the modern

- Pacific Acanthochaetetes community. The genus Acanthochaetetes is first reported from the Albian Mural Limestone in Arizona (USA). From a late Cenomanian hardground (Liencrees, Northern Spain) a deeper water sphinctozoan demosponge community is described (Vaceletia / Acanthochaetetes community) which has also a close correspondence to some modern occurrences of coralline sponges within deeper water environments of Indopacific reefs. The extant Indopacific Acanthochaetetes / Vaceletia community and the Mediterranean coralline Calcareia community are relict faunas ("living fossil communities "); from the mid-Cretaceous Tethyan Ocean.</ABSTRACT>

- 70365 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 101, 2: 215-230.</SOURCE>
- 70366 <ABSTRACT>Twenty-seven Tertiary species belonging to the cosmopolitan reef-building scleractinian genus Actinacis, have been described in the literature. A detailed systematic revision has been carried out for Italian and European species by thin section measurements of material mostly sampled from several Italian localities, by observation of some holotypes and topotypes and accurate examination of the available literature. A combination of several measured corallite morphologic characters and diagnostic features is proposed as a reliable tool for species recognition. Results indicate that only three species, of the twelve described for the Italian Tertiary sites, actually belong to the

genus Actinacis. Moreover, a list of synonyms and a stratigraphic range chart of the established species are proposed. An approximate taxonomic identification and stratigraphic distribution are given for those species not included in the systematic revision. Preliminary examination of the stratigraphic and geographic distribution of Actinacis species suggests that: 1) the Tertiary distribution of the genus ranges from the Late Paleocene to the Late Oligocene (from Late Cuisian to Middle Chatian as concerns Italy); 2) the highest species diversity occurred during the Middle Eocene, when the genus consisted of a relatively large number of geographically restricted species; 3) only two widespread species survived the Eocene/Oligocene turnover and reached the Late Oligocene, when the genus became globally extinct.

70377 <TITLE>Présence d'une structure septale de type Montlivaltide chez Trochosmilium, Madréporaire Eocene.</TITLE>

70378 <SOURCE>Annales de Paléontologie 1973: 35-80.</SOURCE>

70379 <ABSTRACT>In the Jurassic genera Montlivaltia, Stereophyllia and Thecosmilium and in Cyclostraea spinosa of Cenomanian age, Gill (1970) and Gill and Lafuste (1971) have recognized a common structure to the septa. This structural pattern is characterized by trabeculae, rhombic in transverse section, which compose a median part often thickened by laminar layers. Described in the two above-mentioned works, this type of septa was proposed as a basis for the superfamily Montlivaltiidae All. 1952 emend. Gill and Lafuste, 1971. The authors suggested as well that such a septal scheme existed also from the Upper Cretaceous and onwards. A collection of Eocene corals from Northern Italy permits the time upper limit of this structure to be extended into the Tertiary due to its discovery in Trochosmilium corniculum (Mich.) and other genera still under study. The inventory of corals having a Montlivaltid septal type is for the time being rather small and an elaboration of a detailed classification within the superfamily is therefore premature. Nevertheless, a comparison of characters of the aforementioned genera emphasizes the distinction of two groups, one containing Montlivaltia, Stereophyllia and Thecosmilium, the other Cyclostraea and Trochosmilium. In the present work Trochosmilium corniculum (Mich.) from the Eocene of Capo Mortola, province of Imperia (Northern Italy) is described. The neotype, chosen by Alloiteau for the genus Trochosmilium is lost but a thin section of it still exists permitting the identity of T. corniculum from Italy to be confirmed. A complementary description of the genotype Cyclostraea spinosa is given in order to demonstrate its relationship with Trochosmilium.</ABSTRACT>

- 70417 <SOURCE>Proceedings of the Royal Society of London (B) 273, 1589: 975-982.</SOURCE>
- 70418 <ABSTRACT>*Acropora* is the most diverse genus of reef-building corals in the world today. It occurs in all three major oceans; it is restricted to latitudes 31°N-31°S, where most coral reefs occur, and reaches

greatest diversity in the central Indo-Pacific. As an exemplary genus, the long-term history of *Acropora* has implications for the evolution and origins of present day biodiversity patterns of reef corals and for predicting their response to future climate change. Diversification of *Acropora* was thought to have occurred in the central Indo-Pacific within the previous two million years. We examined Eocene fossils from southern England and northern France and found evidence that precursors of up to nine of 20 currently recognized *Acropora* species groups existed 49–34 Myr, at palaeolatitudes far higher than current limits, to 51°N. We propose that pre-existing diversity contributed to later rapid speciation in this important functional group of corals.

70469 <SOURCE>FC&P 13, 2: 31-34.</SOURCE>
70470 <ABSTRACT>At the fourth International Symposium on Fossil Cnidaria, held in Washington in August 1983, a small group of attendants met informally to discuss ways of encouraging and co-ordinating studies of Cainozoic (i.e. including Recent) corals. * At the moment, most Cainozoic coral work is concentrated on faunas of a particular region and/or age, but it is also necessary to balance this with more work on the taxonomy of whole systematic groups like genera and families, throughout their geographical and stratigraphical ranges. * It was agreed that the group would especially try to encourage and co-ordinate systematic work and that it should remain very informal. Initially at least, Fossil Cnidaria [FC&P] (and possibly other existing newsletters) will be used as means of circulating information to participants. * In due course it is aimed to devise and announce projects for participation by post, and perhaps, eventually, to hold workshops, e.g. in conjunction with the four-yearly Fossil Cnidarian Meetings. [first fragment of a note; presented is also a circular for gathering info on researchers and their study areas]</ABSTRACT>

70495 <SOURCE>Geol. Soc. London Spec. Publ. 83 [D.W. Bosence & P.A. Allison (eds): Marine Palaeoenvironmental Analysis from Fossils]: 181-229.</SOURCE>
70496 <ABSTRACT>The value of quantitative surveys of ancient reef slopes for palaeobathymetrie analysis is reviewed. Reefs are selected for palaeobathymetrie analysis because they are characterized by in situ preservation of benthic communities which are often depth related. In addition, if the reef crest and slope are preserved then ancient water depths can be measured. The zonation of living reefs has been measured using semi-quantitative phytosociological methods as well as a range of plot and plotless techniques, but there is little agreement as to a single best method. For this study a modified line intercept transect method is selected as it may be used on both living reefs and on various types of outcrops of fossil reefs. This method minimizes

problems arising from outcrop conditions, is faster than quadrat methods, can be used to assess different frame-building taxa, matrix, cement and porosity along ancient reef surfaces, and is also frequently used in studies of living reefs. [first part of extensive summary]

70508 <SOURCE>Eclogae Geologicae Helvetiae 98, 2: 169-187.</SOURCE>

70509 <ABSTRACT>Historically, the genus *Culicia* (Anthozoa Scleractinia) was known (until Chevalier 1961) as beginning in the Burdigalian of Basse-Provence (France). The study of new crops in Aquitaine Basin as well as works in varied collections, show that the species *Culicia parasita* (Michelin 1847) has been living in this region since the Oligocene (Chattian), which is a noticeable extension of the stratigraphical range of this genus. This species is here amply illustrated, with specimens from each concerned stage, and paleoecologic data are provided. Otherwise, a whole bibliographic review of references concerning the genus *Culicia*, added to the new collection made in the western France and Mediterranean Neogene, mainly fills the classical stratigraphic hiatus recorded in the distribution of this genus between the Middle Miocene of Eastern Atlantic and the Pliocene-Quaternary of Australia; the question of possible phyletic relations between fossil and extant *Culicia* species is set. A map of biogeographic migration is proposed, including all the taxa of this genus.</ABSTRACT>

70520 <TITLE>Recognizing species of Late Cenozoic Scleractinia and their evolutionary patterns.</TITLE>

70521 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.): Paleobiology and Biology of Corals]: 59-80.</SOURCE>

70522 <ABSTRACT>New morphometric methods for distinguishing morphologically similar species of Recent colonial scleractinian corals involve the analysis of three dimensional landmarks digitized on calical surfaces. Variables suitable for multivariate statistical analysis are derived from the landmark data by applying various geometrical techniques, including Bookstein size and shape coordinates and generalized resistant fitting. Cluster analyses of these variables and study of the relative positions of replicates from the same colony on the resulting dendrograms are used to recognize clusters of colonies representing morphospecies. Comparisons with the results of genetic analyses on the same specimens suggest that these morphospecies correspond closely with biological species. Although slightly less effective, similar analyses of two dimensional landmark data collected on thin sections of the same specimens also distinguish species, and suggest that biological species

can be approximated in the fossil record. Multivariate statistical analyses show that variables derived from two dimensional landmarks can be used to trace the stratigraphic ranges of these fossil species. The appropriate method for tracing ranges depends of the evenness of sampling in different geologic horizons. Preliminary comparisons of observed stratigraphic ranges determined by this approach with those determined by cladistic analysis suggest that overall patterns in evolutionary rates through geologic time are the same for both approaches. Thus, nontraditional morphologic characters determined by subsequent examination of morphometrically-defined species have potential for providing sufficient resolution for phylogenetic analysis.

- 70560 <SOURCE>Paläontologische Zeitschrift 73, 3/4: 217-240.</SOURCE>
- 70561 <ABSTRACT>This report presents a systematic revision of the Tertiary species of the common reef-building coral Hydnohpora. Major diagnostic characters of various Tertiary genera that have been commonly confused with Hydnohpora (Leptoria, Monticulastraea, Staminocoenia, Michelottiphyllia and Angeliphyllia) are defined and subsequently compared in order to establish differences and synonymies. With the exception of Leptoria, all other genera are considered synonyms of Hydnohpora. * Forty-five Tertiary species ascribed to Hydnohpora, or to synonymous genera, have been revised and type material analyzed. Collected material from Oligocene Italian localities and Miocene localities from Somalia and Pakistan has been also analyzed in order to provide a consistent taxonomy for distinguishing species within the genus, especially for the Mediterranean Tertiary. * According to this report, of the forty-five species of Hydnohpora previously described, only twenty-one to be distinct. The Tertiary distribution of the genus, which started in the Late Paleocene, clearly shows that species richness increased significantly from Paleocene to Miocene. Originations of species were mostly concentrated during two time intervals, respectively the Chattian for the Mediterranean and the Burdigalian for the Eastern Tethys. As regards the Mediterranean, the genus developed only during Chattian time with five fully described species. The genus became extinct in both Caribbean and western-central Mediterranean regions at the end of the Oligocene and subsequently developed in eastern Tethys regions during the Miocene. * A new name is proposed for the only Paleocene species: Hydnohpora gregoryi. 70612 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunkel F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
70613 <ABSTRACT>Encrusting organisms play key roles in the development of reefs and carbonate sedimentation. In this study two small scaled encrustation phenomena consisting of encrusted echinoids and macroid formation from the lower Miocene are investigated quantitatively and compared with other examples including those from the Recent. The dominating encrusters are bryozoans followed by balanids, serpulids and coralline algae. The methods used were image analysis programs assessing percentage of encruster coverage as well as sphericity determination of the macroids. The results point to the complexity of encrustation sequences, the importance of growth form strategies, the interpretation of encrusted macrofossils and macroids as carbonate factories as well as the possible influence of soft-bodied organisms.

70650 <TITLE>Genetic control of septal numbers and the species problem in a fossil solitary scleractinian coral.</TITLE>
70651 <SOURCE>Lethaia 16, 3: 185-191.</SOURCE>
70652 <ABSTRACT>Intraspecific morphological variations of a Pleistocene scleractinian coral, *Cylindrophylia orientalis* (Yabe & Eguchi), have been examined based on 792 specimens. The specimens are discoidal to short cylindrical in shape, with no significant change in their diameter during skeletal growth. Septal arrangements of the coralla are observed on upper and basal surfaces. Septal numbers do not change through the ontogeny of each corallum, even when the last cycle of septa is incomplete. Septal arrangements and numbers are controlled by intrinsic genetic factors. Heights of the coralla are controlled by environmental factors where they lived. If growth rates are presumed to be constant, heights can be regarded as indicating age of specimen. Assuming that this is the case, the survivorship curve shows that this fossil population had a constant death rate. Two varieties exist in this population: one has 20-28 septa, the other 30-40 septa, showing a dimorphic feature.</ABSTRACT>

70663 <TITLE>Intraspecific morphological variations in a Pleistocene solitary coral, Caryophyllia (Premocyathus) compressa Yabe & Eguchi.</TITLE>
70664 <SOURCE>Journal of Paleontology 61, 1: 21-31.</SOURCE>
70665 <ABSTRACT>Intraspecific morphological variations have been investigated based on 1.090 specimens of a Pleistocene solitary scleractinian coral, Caryophyllia (Premocyathus) compressa Yabe & Eguchi. Special attention has been paid to variations in special arrangements, septal numbers, insertion patterns of third cycle septa, and pali. The specimens contain nine different septal plans from hexamerall to decatetramerall, among which those having a decamerall plan are the most common. There is a clear regularity in number and position of the third-cycle septa. Specimens in which the third cycle is incomplete are also considered to be mature forms. Number and position of pali are intimately related to the number and insertion pattern of the third-cycle septa. In extreme cases, there exist specimens having only two cycles of septa and lacking pali. Ninety-nine varieties in septal arrangements are considered to be present in the fossil population, although only 57 have been found in the collection. The present species includes many specimens which do not show bilateral symmetry.</ABSTRACT>

70819 <TITLE>Coral reef diversity refutes the neutral theory of biodiversity.</TITLE>

70820 <SOURCE>Nature 440, 2: 80-82. [letter to Nature]</SOURCE>

70821 <ABSTRACT>The global decline of coral reefs highlights the need to understand the mechanisms that regulate community structure and sustain biodiversity in these systems. The neutral theory, which assumes that individuals are demographically identical regardless of species, seeks to explain ubiquitous features of community structure and biodiversity patterns. Here we present a test of neutral-theory predictions with the use of an extensive species-level data set of Indo-Pacific coral communities. We show that coral assemblages differ markedly from neutral-model predictions for patterns of community similarity and the relative abundance of species. Within local communities, neutral models do not fit relative abundance distributions as well as the classical log-normal distribution. Relative abundances of species across local communities also differ markedly from neutral-theory predictions: coral communities exhibit community similarity values that are far more variable, and lower on average, than the neutral theory can produce. Empirical community similarities deviate from the neutral model in a direction opposite to that predicted in previous critiques of the neutral theory. Instead, our results support spatio-temporal environmental stochasticity as a major driver of diversity patterns on coral reefs. 70832 <TITLE>Coral communities are regionally enriched along an oceanic biodiversity gradient.</TITLE>

70833 <SOURCE>Nature 429: 867-870. [Letters to Nature]</SOURCE>

70834 <ABSTRACT>Ecological communities are influenced by processes operating at multiple scales. Thus, a better understanding of how broad- as well as local-scale processes affect species diversity and richness is increasingly becoming a central focus in modern community ecology. Here, in a study of unprecedented geographical scope, we show significant regional and local variation in the species richness of coral assemblages across an oceanic biodiversity gradient. The gradient that we sampled extends 10.000 km eastwards from the world's richest coral biodiversity hotspot in the central Indo-Pacific. Local richness and the size of regional species pools decline significantly across 15 islands spanning the gradient. In addition, richness declines across three adjacent habitats (reef slopes, crests and flats). In each habitat, a highly consistent linear relationship between local and regional species richness indicates strong regional enrichment. Thus,

even on the most diverse coral reefs in the world, local coral assemblages are profoundly affected by regional-scale processes. Understanding these historical and biogeographical influences is essential for the effective management and preservation of these endangered communities.

70846 <SOURCE>Rudolstädtsche naturhistorische Schriften 13: 37-113.</SOURCE>

70847 <ABSTRACT>In the Naturhistorisches Museum of the Thüringer Landesmuseum Heidecksburg at Rudolstadt (Thuringian State Museum Heidecksburg) there is with 271 species a rich collection of stony corals. The earliest specimens of it are older than 200 years. In former times they were belonging to the royal natural cabinet, but nearly than 400 specimens were collected recently by diving in the Caribbean Sea, the Mediterranean Sea, the Red Sea, the Indian Ocean, the Pacific and adjacent waters. Among them are rare and fragile corals, i.e. *Leptoseris papyracea* (Dana 1846), *Acropora scabra* Vaughan 1907, and *Galaxea horrescens* (Dana 1846) from the deeper water of the reef front. Two paratypes of *Stylophora kuehlmanni* Scheer & Pillai 1983 and *Stylophora mamillata* Scheer & Pillai 1983 were collected in the Red Sea. Some new discoveries, shore, geographical and ecological information are given.</ABSTRACT>

70858 <TITLE>Paleotemperatures from deep-sea corals: Overcoming vital effects.</TITLE>

70859 <SOURCE>Palaios 15, 5: 25-32.</SOURCE>

70860 <ABSTRACT>Thirty-five azooxanthellate (non-photosynthetic) corals belonging to 18 species were collected at sites ranging from the Norwegian Sea to the Antarctic and of depths ranging from 10 to 5220m. All specimens showed distinct, well-defined linear correlations between carbonate oxygen and carbon isotopic composition, with slopes ranging from 0,23 to 0,67 (mean 0,45 ± 0,9) and linear correlation r² values that averaged 0,89. These pronounced isotopic disequilibria have, to date, rendered azooxanthellate corals unsuitable for use in paleothermometry. Most, but not all, of the heaviest skeletal δ¹⁸O values reached or approached equilibrium. If the isotopically-heavy ends of the δ¹⁸O vs δ¹³C regression lines reliably approximated isotopic equilibrium with seawater, these values could be used to estimate the temperature of the water in which the coral grew. The δ¹³C values of the heavy ends of each line, however, were always depleted compared to carbon isotopic equilibrium with ambient bicarbonate by varying amounts. * Despite the disequilibria, a reliable method for obtaining paleotemperature data was obtained. It was found

that, if a $180 \text{ vs } 13\text{C}$ regression line from an individual coral could be generated, the 180arag value corresponding to $13\text{Carag} = 13\text{Cwater}$ and corrected for 180water was a linear function of temperature: $180 = 0,25 \text{ T}(\text{°C}) + 4.97$.

70937 <SOURCE>C. R. Acad. Sc. Paris 307, III, Medecine et Therapeutique: 485-491.</SOURCE>
70938 <ABSTRACT>The biocompatibility of mammal bone with aragonite and calcite skeletons of aquatic invertebrates (Corals, Molluscs) led us, after animal experimentation, to implant in humans artificial dental roots derived from such invertebrates. These roots, incorporated but not resorbed, serve as supports for a prosthetic crown; they are equipped to isolate the root from the buccal cavity and to ensure shock absorption during mastication. The greater ease of implanting artificial teeth and their excellent acceptance will in many cases modify the strategy of current dental treatment.</ABSTRACT>

70949 <TITLE>Complexity of Coral Interactions: Influence of Time, Location of Interaction and Epifauna.</TITLE>
70950 <SOURCE>Marine Biology 69: 215-222.</SOURCE>
70951 <ABSTRACT>The potential role of competition for space in a community depends on the arrangement of interaction relationship. A survey (255 m²) of the interactions between corals (Scleractinia) on a Caribbean reef (depth 10-30 m) indicated the outcome of 17-35% of the aggressive and defensive interactions to be unpredictable. Experiments on the reef (depth 7-13 m) with pairs of interacting corals - *Madracis mirabilis* (Duchassing et Michelotti), *Agaricia agaricites* (L.), *Montastrea annularis* (Ellis et Solander), *Eusmilia fastigiata* (Pallas) - showed that, after the initial contest through extracoelenteric digestion, there are at least two additional processes which can result in a reversal of dominance: interference by epifauna and sweeper tentacle development. Moreover, the impact of extracoelenteric digestion and the extent of sweeper tentacle development varied over the surface of the corals. Employing laboratory and field experiments to distinguish

between the impact of extracoelenteric digestion, epifauna behaviour and sweeper tentacles, we show the three processes combined to explain the coral interaction process in toto. The outcome of the interaction process on the reef depends on numerous, partly unpredictable, variables, including mode of contact and effects of position. Consequently, patterns of community organization resulting from spatial competition will be slow to emerge and easily erased prematurely by disturbances.</ABSTRACT>

70962 <TITLE>A review of modern coral $\delta^{18}O$ and $\delta^{14}C$ proxy records.</TITLE>

70963 <SOURCE>Earth-Science Reviews 81, 1-2: 67-91.</SOURCE>

70964 <ABSTRACT>This paper is a review of published modern coral $\delta^{18}O$ and $\delta^{14}C$ isotopic records that are at least 30 and 20 years long, respectively. The data are presented to show basin-scale trends in both of these proxy records on decadal-to-centennial timescales. The goal was to qualitatively integrate the general inter-annual-to-centennial timescale variability revealed in these data, as well as the statistical and modeling output results that have been produced using these coral records. While many review papers typically include a representative subset of the data available, this review aims to include as much of the available data as possible. In general, coral $\delta^{18}O$ records show a long-term warming and/or freshening throughout the tropical oceans, and agree with the NOAA Extended Reconstruction Sea Surface Temperature 2 (ERSST) on decadal timescales. In the western Pacific, it is most likely a freshening of the seawater $\delta^{18}O$ that dominates the signal. El Niño Southern Oscillation (ENSO) variability dominates most $\delta^{18}O$ records either by varying local seawater temperature or salinity, depending on the regional oceanography/climatology. Outside of the Pacific, ENSO affects seawater temperature and salinity via atmospheric or oceanic teleconnections. Post-bomb coral $\delta^{14}C$ records collectively show that the uptake of ^{14}C has been greatest in gyre-water fed sites, followed in descending order by western boundary current areas, equatorial upwelling regions, and eastern tropical Pacific upwelling sites. These surface water $\delta^{14}C$ values indicate the proportion of surface water and/or the residence time of water at the surface at a given location, and can be used to model water mass mixing rates. Such models have only begun to be run and show that the amount of eastern Pacific water entering the central South Pacific increases during El Niños and that the Indonesian throughflow is supplied year-round by the North Pacific. Comparing ocean circulation models with coral $\delta^{14}C$ -modelled circulation enables researchers to explore the mechanisms that drive seawater $\delta^{14}C$ variability and fine-tune their models. In addition, our comparison between the rate of coral $\delta^{14}C$ increase between 1960 and 1970 and total anthropogenic CO₂ uptake rates show general agreement, demonstrating the value of coral records in understanding past carbon fluxes. Overall, coral $\delta^{18}O$ and $\delta^{14}C$ proxy records represent natural archives of seawater conditions and are critical for studying the natural variability in local and regional patterns within, and teleconnection patterns between, the tropics, extra-tropics, temperate, and Polar Regions on intra-annual-to-centennial timescales. 71001 <TITLE>Hydraulic exchange between a coral reef and surface sea water.
</TITLE>
71002 <SOURCE>Geological Society of America Bulletin 104: 1280-1291.</SOURCE>
71003 <ABSTRACT>Hydraulic exchange between overlying sea water and the
internal structure of a patch reef in Kaneohe Bay, Oahu, Hawaii, was
studied with an array of wells 1, 2, and 4m deep. Two natural chemical
tracers, radon, and salinity, were used to calculate the exchange rate
between surface sea water and reef interstitial waters. Dissolved radon
concentrations are substantially higher in interstitial waters than in
surface water. The degree of radon enrichment is quantitatively related
to the time elapsed since interstitial water had equilibrated with the
atmosphere. Residence time estimates are 1-40 days, with deeper wells
having slower exchange. The average residence time for 1-m-deep wells
was 2.1 days. A rainstorm-induced dilution of the salinity of Kaneohe
Bay provides the second tracer. Samples of surface and reef
interstitial waters following this salinity perturbation are used to
calculate an average residence time of 2.6 days at a depth of 1m and 42
days at a depth of 2m. Three types of physical forces thought to cause
exchange between surface and interstitial water are considered by
measurement of the forcing functions and reef permeability. Hydraulic
conductivities are about 50 m/d, with lower values near the seaward
side of the reef. Most exchange seems to be caused by high-frequency,
wave-driven oscillatory pumping and by unidirectional hydraulic head
gradients (of uncertain origin) that are stable for at least 3-4 days.
Wave-driven mixing is probably more important shallower in the reef,
whereas head-driven flow may dominate deeper in the reef. Tidal pumping

does not seem to contribute to exchange. All methods indicate that exchange in the upper part of Checker Reef is primarily through vertical exchange. The best estimate for the residence time of water at a depth of 1m is 2 days. Water at depths of 2-4m probably has a residence time of weeks to months.</ABSTRACT>

71027 <TITLE>Sediment-Shifting Experiments: A Guide to Functional Behavior in Colonial Corals.</TITLE>
71028 <SOURCE>In Boardman, Cheetham, and Oliver (eds): Animal colonies (Dowden, Hutchinson & Ross, Inc., Stroudsburg, Pa.): 31-42.</SOURCE>
71029 <ABSTRACT>Four species of Porites were selected from the Florida reef tract for experimental studies designed to determine the functional relationship of the polyp to the calcareous skeleton. Each species was subjected to systematic sediment-shedding and cursory feeding and calibrated current-flow experiments, crude lethal-limit studies of their temperature and salinity tolerances, and time-marked growth studies under laboratory conditions. At the end of these experiments branches of Porites furcata Lamarck and P. divaricata Lesueur were prepared for standard histological and petrographical observations. An analysis of these results shows that Porites is neither truly colonial nor truly polystomous; it possesses diagnostic characteristics of both these types of organization and is therefore designated quasi-polystomous. It is a colonial coral in which the polyps comprise incomplete individuals with a common enteron; but they also have distinct stomodea and tentacular rings which are capable of independent action. Porites also possesses unique regenerative properties which probably help it to survive adverse conditions. * Examples are given from other Floridian reef corals from known environments of the gradations in coloniality indicated by wells (this volume). Thus structurally linked colonial corals show behavioral responses which range from solitary reactions in Mussa angulosa (Pallas) through partial coordination in Porites to complete coordination in Diploria and "brain" corals. Complete confidence as to the behavioral nature of coloniality can only be ascertained from combining histological and behavioral techniques with observations on skeletal anatomy.</ABSTRACT>

71040 <TITLE>Incorporation of strontium into reef coral skeletal carbonate.
</TITLE>
71041 <SOURCE>Geochimica et Cosmochimica Acta 37, 9: 2173-2190.</SOURCE>
71042 <ABSTRACT>220 well-characterized coral specimens from 17 localities
have been analysed for Sr. 73 genera and subgenera, mostly hermatypic
scleractinians, are represented. For some genera, specimens living in
surface reef environments are compared with those from 18,3m depth on
the same reefs. Growth rates for some species have also been measured
at these depths at one of the sampling sites. Skeletal Sr for a given
genus decreases with increasing water temperature, a relationship which
previously eluded detection. Aragonite deposited by corals living in
the reef at depth of 18,3m contains more strontium than the skeletal
aragonite of the same coral genera from shallow-water, surface
environments. * Quantitative treatment of the data for Acropora, one of
the most abundant and widely distributed of the reef-building corals,
suggests that the observed Sr variations may reflect variations in the
rate of skeletal calcification, rather than direct dependence upon
temperature or water depth. There is evidence for "species effect
", apparently unrelated to growth rate differences, in that certain
coral genera are consistently enriched or depleted in skeletal Sr
content relative to other genera living in the same reef environments
under identical ambient conditions. Temperature, salinity, water depth,
sea-water composition and/or other such parameters may in part
determine the levels of trace element concentration in carbonate
deposited by corals and other marine invertebrates, but it would appear
that these variables more directly affect physiological processes which
in turn control skeletal chemistry.</ABSTRACT>

magnesium from sea-water.</TITLE>
71054 <SOURCE>American Journal of Sci. 274, 1: 84-93. title?</SOURCE>
71055 <ABSTRACT>Little is known about the magnesium content of the skeletal
aragonite deposited by the hermatypic reef-building, scleractinian
corals. Over 2000 corals specimens were analysed in an attempt to
determine the extent to which environmental and genetic factors control
magnesium uptake during skeletogenesis. Only three of the 49 genera
investigated show any evidence that skeletal magnesium levels are
temperature dependent, and even in these 3 cases, the relationship is
poorly defined. Calcification rate and water depth also appear to exert
no detectable influence. There is considerable variability in skeletal
magnesium content, even within a given genus, but patterns linking Mg
concentrations to taxonomic affinity suggest that physiologic controls
predominate in determining the quantity of this element that can enter
the aragonitic skeleton.</ABSTRACT>

71131 <TITLE>Basis for skeletal plasticity among reef-building Corals.</TITLE>
71132 <SOURCE>Geology 1974, 2, 3: 153-154.</SOURCE>
71133 <ABSTRACT>Reef corals are remarkably variable in growth form and skeletal configuration. This high degree of phenetic diversity has contributed greatly to the success of the hermatypic scleractinians as widespread reef builders in tropical oceans. Although phenetic variability or "plasticity" is common, its cause remains obscure, because the species are genetically stable. The extent of phenetic variability is surprising in view of the morphologic simplicity of the animal itself. Carbon isotope ratios have been used to determine changes in the relative proportions of skeletal carbon in the form of carbonate derived from sea-water bicarbonate and metabolic carbon dioxide sources. Increasing amounts of respiratory CO₂ incorporated into skeletal aragonite are attributed to decreasing efficiency of metabolite excretion. Isotope data indicate that zooxanthellae are effectively removing metabolic waste products from the tissues of hermatypic scleractinians, and that, for these corals, diffusion is not an important excretion mechanism. Ahermatypic corals, however, depend on diffusion processes to eliminate metabolic waste products. 13C/12C ratios indicate that, among the ahermatypes, small changes in corallum geometry that result in greater coarctation [?] of the polyps and (or) a decrease in the size of the polyp surface exposed to sea water have a large effect on the isotopic composition of the skeletal carbonate. These findings suggest that corals that do not build reefs are restricted to small and relatively simple forms because of serious difficulties in the metabolite excretion they would encounter in more complex corallum geometries. In the case of the hermatypes, however, the metabolite excretion problems that would limit the range of possible skeletal configurations have been resolved by zooxanthellae. The spectacular phenetic variability in reef corals is thus achieved through a symbiotic association of the hermatypic corals with zooxanthellae.</ABSTRACT>

71157 <TITLE>Distribution and nature of incorporation of trace elements in modern aragonite corals.</TITLE>
71158 <SOURCE>Sedimentology 20: 47-64.</SOURCE>
71159 <ABSTRACT>The objective of this study is to locate as closely as possible the sites of strontium, magnesium, sodium, and potassium in modern aragonitic corals, specifically whether these cations are adsorbed, or are substituted in the carbonate lattice or are incorporated in organic components. In addition to locating the sites of each of these four elements we wanted to find out quantitatively how much of each element occurs at each site. The experiments in this study are based on the dissolution rate of aragonite in distilled water and on the substitution of strontium and magnesium by calcium and sodium. Special attention has been given to the occurrence of strontium, magnesium, sodium and potassium in the organic components of the corals. * The main site for strontium in the corals is in the aragonite lattice. Twenty-five per cent of the total magnesium occurs in adsorbed sites and in organic compounds. The rest of the magnesium may be located in the aragonite lattice, but it is easily removed by repeated leaching or by replacement with calcium ions. Another possibility is that magnesium may occur in a dispersed mineral phase more soluble than aragonite because magnesium was released at a higher Mg to Ca ratio than is found in the solid coral; also because no local concentration of magnesium could be detected with an electron microprobe. About 12% of the total sodium is in adsorbed sites and is included in the organic compounds. The rest of the sodium might be in the lattice replacing calcium, but the low total exchange capacity is not enough to provide the needed charge balance. Another possibility is that sodium is located in a proposed mineral phase. Potassium is in adsorbed sites and incorporated in the organic compounds to an extent greater than all the other elements studied (30% of the total potassium), but again the evidence suggests that the remaining potassium is in a proposed mineral phase. * Calcite is detected on the surfaces of aragonite corals after 5 months in the substitution experiment. The change of aragonite to calcite took place after the inhibitor magnesium was exchanged from the surface sites and replaced by calcium. * The organic compounds in corals contain small amounts of strontium, magnesium, sodium and potassium. Strontium is preferentially enriched in the organic compounds over magnesium.</ABSTRACT>

71171 <SOURCE>Annales de la Societe geologique de Belgique 97, 1: 145-152.</SOURCE>
71172 <ABSTRACT>Des observations réalisées sur des coraux vivants, tant sur le récif qu'en aquarium, ont permis d'intégrer les caractéristiques de leur distribution zonéographique aux propriétés fonctionnelles de leur morphologie squelettique. Les relations existant entre la nature et le taux d'activité des polypes, d'une part, et la morphologie du squelette, d'autre part, sont d'abord discutées: la micromorphologie des septes ainsi que leur angle de divergence, la forme des calices et l'orientation des corallites sont mises en relation avec la paramètres physiques du milieu. De là, l'auteur tire des arguments rendant compte de la distribution spatiale des espèces considérées. * Ces observations sont ensuite transposées dans le passé et servent de fil conducteur à l'interprétation des relations existant entre la distribution de Rugueux paléozoïques et les caractères des sédiments associés.</ABSTRACT>

- 71289 <ABSTRACT>Korallen (vor allem Scleractinia und Oktokorallen) aus dem Besitz von Dr. H.C. Carl Weber-Sulzer (1845-1915) ausgestellt. Diese Sammlung zeigt einen recht guten Querschnitt durch die Formenvielfalt der Korallenfaunen des Roten Meeres, Indischen Ozeans und des Pazifiks sowie z.T. auch von Bermuda und den Antillen. Verschiedene der Korallenkolonien besitzen ungewoehnlich grosse Ausmasse, wie sie nur selten in europaeischen Museen aufbewahrt werden. Obwohl die wissenschaftlichen Namen auf den Etiketten meist nicht der modernen Korallen-Taxonomie entsprechen, kann die Sammlung doch fuer Spezialisten der weiteren Region bei vergleichenden Untersuchungen von grossem Nutzen sein, vor allem, da derartig grosse Kolonien auch heute nicht ohne beträchtlichen technischen und finanziellen Aufwand gesammelt und bis nach Europa transportiert werden koennen. 71313 <TITLE>The ultrastructure of skeletogenesis in hermatypic corals.</TITLE>
71314 <SOURCE>International Review of Cytology 67, 171-214.</SOURCE>
71315 <ABSTRACT>A structural organic matrix is present in the adult skeleton of Pocillopora damicornis. One component of this structural matrix is present transiently at the growth surface of the skeleton, and it consists of individual sheaths enveloping each forming aragonite crystals. These crystal sheaths, plus some small extracellular vesicles that are presumed to represent a precursor for the sheaths, are together implicated in the following hypotheses for coral calcification. * 1. The precipitation of calcium carbonate, and thereby skeletal accretion, occurs only within the crystal sheaths, i.e. within the terminal matrix compartments. * 2. The crystal sheaths have a role in crystal nucleation. * 3. The sheaths isolate and actively modify the space within these compartments, thereby controlling the rate of epitactic crystal growth subsequent to nucleation. * 4. The movement of calcium ions from seawater toward the skeleton is principally via a paracellular route. * 5. The matrix precursor vesicles, by analogy with vertebrate matrix vesicles, have a role in the transport of calcium and/or carbonate ions from the lateral extracellular spaces of the calicoblastic ectoderm to the growth surface of the skeleton. * 6. The synthesis of matrix precursor material by the calicoblast cells is enhanced in the presence of photosynthetic products translocated to the coral tissues from the zooxanthellae. 71327 <SOURCE>Oxford University Press, 352 pp. ISBN 978-0-19-856635-9</SOURCE>
71328 <ABSTRACT>Coral reefs represent the most spectacular and diverse marine ecosystem on the planet as well as a critical source of income for millions of people. However, the combined effects of human activity have led to a rapid decline in the health of reefs worldwide, with many now facing complete destruction. * This timely book provides an integrated overview of the function, physiology, ecology, and behaviour of coral reef organisms. Each chapter is enriched with a selection of 'boxes' on specific aspects written by internationally recognised experts. As with other books in the Biology of Habitats series, the emphasis in this book is on the organisms that dominate this marine environment although pollution, conservation, climate change, and experimental aspects are also included. Indeed, particular emphasis is placed on conservation and management due to the habitat 's critically endangered status. A global range of examples is employed which gives the book international relevance.</ABSTRACT>

71367 <ABSTRACT>we present evidence for the formation of woven bone between human maxillary lamellar bone (the target site), and a coral implant (Corallium johnsoni Gray). This newly formed bone is characterized by numerous osteocytes located in spherical lacunae and having many ramified processes directed towards the coral; some of these processes continue into the implant surface. Healthy osteocytes were detected within the superficial part of the coral, next to the newly formed bone. Neither osteoclast nor surface of resorption has been noticed.</ABSTRACT>

- 71378 <TITLE>Compositional diversity of soluble mineralizing matrices in some recent coral skeletons compared with fine-scale growth structures of fibres. Discussion of consequences for biomineralization and diagenesis. </TITLE>
- 71379 <SOURCE>International Journal of Earth Sciences [Geol. Rundsch.] 88, 3: 582-592.</SOURCE>
- 71380 <ABSTRACT>In contrast to the purely crystalline model of the coral fibre, a transversal zonation is made visible within fibres by specific preparations (enzymatic or light acidic etchings). This growth zonation that corresponds to the successive positions of the secretory ectoderm during septal development shows that crystallization of coral fibre is controlled not only by an external organic coating of fibres, but also includes intra-fibrous organic components. This results in a micron-scaled internal structure of fibres, with a noticeable diversity depending on species. In parallel, soluble matrices also exhibit significant differences, although the global high content in acidic amino acids is always observed. Gathering these two sets of data allows the current ideas concerning structures and growth modalities of coral septa to be discussed. Basically, the respective role of centres of calcification and fibres during septal development appears clearly different from the current ideas, resulting in significant change in interpretation of coral structures, with concerns in both skeleton formation and understanding of diagenetic processes. - 71393 <ABSTRACT>Verons's award winning Corals of Australia and the Indo-Pacific, first published in 1986 and now considered a classic, is completely eclipsed by Corals of the world. The book is one of the most comprehensive, authoritative and spectacular productions ever given to a group of marine organisms, the reef-building corals worldwide. * Brief characteristics: (1) an extravaganza of colour and art - a portrayal of the variety and the beauty of corals as never before - over 3.000 underwater photographs including hundreds taken by the best underwater photographers from around the world; (2) from reefs to aquaria - a history of discovery - which comes first - the reefs or the corals? - corals in aquaria: a path of interest and discovery; (3) 900 distribution maps - an atlas of information and explanation - one hundred superb works of art reveal the beauty of microscopic detail; (4) what are species - the nature of species, how they vary according to environment and how they change geographically; (5) encyclopaedic information - one in ten species is new to science; there are several new genera and a new family; this book is the outcome of comprehensive taxonomic revisions of all reef-building corals - non-technical summaries of the distinguishing features of all species, genera and families - information about the colours, habitats and abundances of all species - references to taxonomic detail and regional field guides - chapters on what are species?, evolution, biogeography, the fossil record, coral reefs, the structure of corals, reproduction and the history of coral studies; (6) reproduction and dispersal - the reproduction and dispersal mechanisms of corals - how reproduction and dispersal relate

to biogeographic and evolutionary issues; (7) structure - a non-technical account of coral morphology - a glossary explains all terminology; (8) geological history - an account of the **big picture** of evolutionary change; (9) evolution - the mechanisms which control the origin and evolutionary change in species - an original concept of **reticulate** evolution which integrates the information and observations presented throughout the book.

71404 <TITLE>Learning from the collector: a survey of azooxanthellate corals affixed by xenophora (Gastropoda: Xenophoridae), with an analysis and discussion of attachment patterns.</TITLE>

71405 <SOURCE>Nautilus 112, 3: 73-83.</SOURCE>

71406 <ABSTRACT>All species of the gastropod family Xenophoridae affix foreign objects to the upper shell surface. Affixed objects may include bivalve shells, smaller gastropod shells, shell fragments, and coral skeletons, as well as a wide array of inorganic material. In deep water, xenophora may serve as useful proxy collectors of benthic organisms. Since 1842, coral skeletons have been noted among the attached objects, but this association has never been studied in detail. This paper surveys 227 Xenophora shells, comprising 8 species from 69 stations, for affixed azooxanthellate corals. Five hundred and eighty-one coralla were found, representing 74 coral species, 2 of which remain undescribed. Twenty-four of the affixed coralla were alive at the time the xenophora hosts were collected; xenophora not only collect the corals, but corals can remain alive long after being affixed. Corals were found at 6 sites where they had previously been unknown, and the geographic ranges of 29 species of coral were expanded as a result of specimens found on Xenophora. * This paper has two sections. In the first, quantitative observations were made on the orientation of affixed corals; statistical analysis of these observations revealed non-random patterns of attachment, based on orientation of both the long axis of the coral and the coral calice. Qualitative observations suggest that species of xenophora favor corals of particular shapes. In the second section, the speculations of previous authors regarding the ecological basis for attachment behavior are summarized and new theories are discussed. Four of these explanations suggest defensive adaptations, and the remaining 3 are functional support adaptations. Three of these hypotheses (armor, tactile camouflage, and snow-shoeing) are proposed for the first time in this paper. [original abstract]</ABSTRACT>

- 71432 <SOURCE>Nature 428: 66-70. [letter to Nature]</SOURCE>
- 71433 <ABSTRACT>Zooxanthellae, endosymbiotic algae of reef-building corals, substantially contribute to the high gross primary production of coral reefs, but corals exude up to half of the carbon assimilated by their zooxanthellae as mucus. Here we show that released coral mucus efficiently traps organic matter from the water column and rapidly carries energy and nutrients to the reef lagoon sediment, which acts as a biocatalytic mineralizing filter. In the Great Barrier Reef, the dominant genus of hard corals, *Acropora*, exudes up to 4.8 litres of mucus per square metre of reef area per day. Between 56% and 80% of this mucus dissolves in the reef water, which is filtered through the lagoon sands. Here, coral mucus is degraded at a turnover rate of at least 7% per hour. Detached undissolved mucus traps suspended particles, increasing its initial organic carbon and nitrogen content by three orders of magnitude within 2 h. Tidal currents concentrate these mucus aggregates into lagoon, where they rapidly settle. Coral mucus provides light energy harvested by zooxanthellae and trapped particles to the heterotrophic reef community, thereby establishing a recycling loop that supports benthic life, while reducing loss of energy and nutrients from the reef ecosystem. - 71446 <SOURCE>Zoologische Mededelingen 78: 209-240.</SOURCE>
- 71447 <ABSTRACT>A new family of antipatharian corals, Aphanipathidae (Cnidaria: Anthozoa: Antipatharia), is established for *Aphanipathes sarothamnoides* Brook and related species. The family is characterized by tall, conical to acicular to cylindrical spines, which can be smooth, papillose or covered with small, conical tubercles, and by polyps that are 0.5-2.5 mm in transverse diameter and have small, subequal tentacles. The family is divided into two subfamilies based on differences in the development of the polypar spines. In the Aphanipathinae the polypar spines are subequal. Genera are recognized on the basis of morphological features of the corallum. *Aphanipathes* Brook (type species *A. sarothamnoides* Brook) has a sparsely to densely branched corallum with straight, usually ascending, branchlets.

- Phanopathes gen. nov. (type species *Antipathes expansa* Opresko & Cairns) forms fan-shaped colonies with short, bilateral branchlets. Pteridopathes, gen. nov. (type species *P. pinnata* sp.nov.) has simple pinnules arranged in two rows. Tetrapathes gen. nov. (type species *Aphanipathes alata* Brook) has simple pinnules arranged in four rows, and Asteriopathes gen. nov. (type species *A. arachniformis* sp.nov.) has simple pinnules arranged in six or more rows. In the Acanthopathinae the circumpolyar spines are considerably enlarged and the hypostomal spines are usually reduced or absent. As in the Aphanipathinae, genera are recognized on the basis of morphological features of the corallum. Acanthopathes gen. nov. (type species *Antipathes humilis* Pourtales) forms candelabra and flabellate colonies and has reduced hypostomal spines. Rhipidopathes Milne Edwards and Haime (type species *Antipathes reticulata* Esper), forms flabellate colonies and has hypostomal spines that are not always reduced in size. Distichopathes gen. nov. (type species *D. disticha* sp.nov.) has simple, straight pinnules arranged in two rows, and Elatopathes gen. nov. (type species *Antipathes abietina* Pourtales) has simple pinnules arranged in four or more rows. </ABSTRACT>

71457 <SOURCE>Zoologische Mededelingen 75: 147-174. </SOURCE>
71458 <ABSTRACT>A new family of antipatharian corals, Myriopathidae (Cnidaria: Anthozoa: Antipatharia), is established for *Antipathes myriophylla* Pallas and related species. The family is characterized by polyps 0.5 to 1.0 mm in transverse diameter; short tentacles with a rounded tip; acute, conical to blade-like spines up to 0.3 mm tall on the smallest branchlets or pinnules; and cylindrical, simple, forked or antler-like spines on the larger branches and stem. Genera are differentiated on the basis of morphological features of the corallum. *Myriopathes* gen. nov., type species *Antipathes myriophylla* Pallas, has two rows of primary pinnules, and uniseriably arranged secondary pinnules. *Tanacetipathes* Opresko, type species *T. tanacetum* (Pourtales), has bottle-brush pinnulation with four to six rows of primary pinnules and one or more orders of uniserial (sometimes biserial) subpinnules. *Cupressopathes* gen. nov., type species *Gorgonia abies* Linnaeus, has bottle-brush pinnulation with four very irregular, or quasi-spiral rows of primary pinnules and uniserial, bilateral, or irregularly arranged higher order pinnules. *Plumapathes* gen. nov., type species *Antipathes pennacea* Pallas, has simple pinnules arranged regularly in two rows. *Antipathella* Brook, type species *Antipathes subpinnata* Ellis and Solander, has simple branchlets/pinnules arranged irregularly in one to four rows. </ABSTRACT>

- Schizopathidae.</TITLE>
71470 <SOURCE>Zoologische Mededelingen 76: 411-442.</SOURCE>
71471 <ABSTRACT>The family of antipatharian corals, Schizopathidae (Cnidaria: Anthozoa: Antipatharia), is revised. The family is characterized by polyps elongated in the direction of the axis and having a transverse diameter of 2 mm or more. Genera are recognized on the basis of morphological features of the corallum. Schizopathes Brook (type species *S. crassa* Brook) has a simple, pinnate corallum with a hook-like holdfast for support in soft sediments. Bathypathes Brook (type species *B. patula* Brook) is characterized by a simple pinnate corallum and a flat discoidal basal plate for attaching to a solid substrate. Parantipathes Brook (type species *Antipathes larix* Esper) has a largely monopodial corallum with simple pinnules in six or more rows. Taxipathes Brook (type species *T. recta* Brook) has a branched corallum and simple pinnules in four to eight rows. Lillipathes gen. nov. (type species *Antipathes lillieii* Totton) has simple pinnules in four rows. Stauropathes, gen. nov. (type species *S. staurocrada* spec. nov.) is branched with simple, bilateral, subopposite pinnules. Abyssopathes, gen. nov. (type species *Bathypathes lyra* Brook) is monopodial with two rows of simple, lateral pinnules and one (sometimes multiple) row of simple or branched anterior pinnules. Dendrobathypathes gen. nov. (type species *D. grandis* spec. nov.) has a branched, planar corallum with two rows of subpinnulated primary pinnules. Saropathes gen. nov. (type species *Bathypathes scoparia* Totton) is monopodial to sparsely branched, with four rows of subpinnulated primary pinnules.</ABSTRACT>

71483 <SOURCE>Zoologische Mededelingen 77: 495-536.
<http://www.repository.naturalis.nl/record/216169></SOURCE>
71484 <ABSTRACT>The family of antipatharian corals Cladopathidae (Cnidaria: Anthozoa: Antipatharia) is revised. The family is characterized by polyps 2mm or more in transverse diameter, six primary mesenteries, and no secondary mesenteries. The family is divided into three subfamilies: Cladopathinae Kinoshita, Hexapathinae subfam. nov. and Sibopathinae subfam. nov. The subfamily Cladopathinae is characterized by a branched pinnulate corallum with three or more rows of primary pinnules, some of which are subpinnulate. Included in the subfamily are the genera Cladopathes Brook (*C. plumosa* Brook, 1889), Chrysopathes gen. nov. (*C. formosa* spec. nov. and *C. speciosa* spec. nov.) and Trissopathes gen. nov. [*T. pseudotrística* spec. nov., *T. tetracrada* spec. nov., and *T. trística* (van Pesch, 1914)]. The subfamily Hexapathinae is characterized by a monopodial or sparsely branched pinnulate corallum, with two rows of simple lateral primary pinnules and one or more rows of simple or subpinnulate anterior primary pinnules. Included in the subfamily are the genera Hexapathes Kinoshita, 1910 and Heliopathes gen. nov. Hexapathes contains the type species *H. heterosticha* Kinoshita, 1910, as well as *H. australiensis* spec. nov. Heliopathes contains the type species *H. americana*, spec. nov. and *Antipathes heterorhodos* Cooper, 1909. The subfamily Sibopathinae van Pesch is defined by the absence of an actinopharynx. Species in the single genus Sibopathes [type species *S. gephura* van Pesch, 1914, and including *S. macrospina* Opresko, 1993] possess a branched corallum with four to six

- rows of simple pinnules. [original abstract] </ABSTRACT>

- 71510 <ABSTRACT>A new family of antipatharian corals, Stylopathidae (Cnidaria: Anthozoa: Antipatharia), is established for *Arachnopathes columnaris* Duchassaing 1870, and related species. The family is characterized by small polyps, 1.5 mm or less in transverse diameter; small, conical, smooth spines, often distally directed (especially at the tips of the branchlets and/or pinnules); and by the tendency for the pinnules and branchlets to occur in subopposite pairs or to be arranged in verticils of three or four (rarely five) pinnules. In many species adjacent pinnules or branchlets fuse together or anastomose, resulting in the formation of cylindrical, reticulated worm runs along the stem or branches. Genera are established on the basis of morphological features of the corallum. *Stylopathes* gen. nov., includes the type species, *Arachnopathes columnaris* Duchassaing, and is characterized by a monopodial or very sparsely branched corallum. *Triadopathes* gen. nov. contains only the type species *Parantipathes triadocrada* Opresko, and has multiple, vertically directed, stem-like primary branches, arising primarily from the lower parts of the corallum. *Tylopathes* Brook contains the type species *T. crispa* Brook, and is characterized by a flagellate corallum with short, mostly bilateral branchlets.</ABSTRACT>

71573 <TITLE>Characterization of Organic Matrix Proteins Enclosed in High Mg-Calcite Crystals of the Coralline Sponge *Spirastrella* (*Acanthochaetetes*) *wellsi*.</TITLE>
71574 <SOURCE>Goettinger Arbeiten zur Geologie und Palaontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke l F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
71575 <ABSTRACT>Protein components found in freeze-dried specimens of the coralline sponge *Spirastrella* (*Acanthochaetetes*) *wellsi* were separated and characterized. Proteins extracted from skeleton crystals (matrix proteins) contained high concentrations of glycine (16%) as well as enhanced amounts of asparagine/aspartic acid (11%) and glutamine/glutamic acid (10%). At least 10 proteins could be separated by SDS-PAGE. Six of them, with molecular weights between 30 and 45 kDa, may be considered as distinct matrix proteins. The bulk of total soluble proteins as well as all soluble matrix proteins are acidic with pH values below 5. Our results indicate that at least in one stage crystal growth is matrix mediated, i.e. controlled by the sponge.</ABSTRACT>

71612 <TITLE>Oxygen isotope fractionation in marine aragonite of coralline sponges.</TITLE>

71613 <SOURCE>Geochimica et Cosmochimica Acta 64, 10: 1695-1703.</SOURCE>

71614 <ABSTRACT>Oxygen isotope values of the extant Caribbean coralline sponge *Ceratoporella nicholsoni* are compared with published temperatures and $\delta^{18}O$ of water calculated from salinities. The measured values from aragonitic sponge skeletons have a mean offset of $1.0 \pm 0.1\%$ from calculated calcite equilibrium values ($\delta^{18}O_{\text{aragonite-calcite}} = 1.0010$). This is in good agreement with published values from synthetic aragonite. They further agree with published near-equilibrium oxygen isotope values of temperate and cold water molluscs and foraminifera extrapolated to the temperature range of the coralline sponges. These results and the mode of skeleton formation of *Ceratoporella nicholsoni* suggest that these sponges precipitate aragonite close to isotopic equilibrium. * The temperature dependence of oxygen isotopic fractionation between the aragonite of *Ceratoporella nicholsoni* and water is only roughly constrained by the available data, due to the narrow temperature range of the Caribbean reef sites. However, as the data suggest oxygen isotopic equilibrium, we can calculate a well constrained temperature equation combining temperate and cold water equilibrium values from molluscs and foraminifera with our sponge data: $103 \ln \delta^{18}O_{\text{aragonite-water}} = (18.45 \pm 0.4) * 103/T(K) - (32.54 \pm 1.5)$ and $T (^{\circ}C) = (20.0 \pm 0.2) - (4.42 \pm 0.10) * (\delta^{18}O_{\text{a}} - \delta^{18}O_{\text{w}})$; for $3^{\circ}C \leq T \leq 28^{\circ}C$. 71625 <TITLE>Skeletal Formation in the Modern but Ultraconservative Chaetetid Sponge *Spirastrella* (*Acanthochaetetes*) *wellsi* (*Demospongiae*, *Porifera*).</TITLE>

71626 <SOURCE>Facies 34, 1: 193-208.</SOURCE>

71627 <ABSTRACT>The modern hadromerid coralline sponge *Spirastrella* (*Acanthochaetetes*) *wellsi* exhibits a unique secondary high-Mg calcite ($\approx 19 \text{ mol } \% \text{ MgCO}_3$) basal skeleton. The basal skeleton is constructed of bundles of elongated crystals more or less tangentially orientated. The initial formation of these crystals is controlled by soluble highly acidic aspartic and glutamic-rich (40%) macromolecules. The skeletal mineralization occurs in four different loci: in the top of the calicles, at the tabulae, on collagenous anchor fibres, and within closed spaces between the tabulae. The calicle walls are formed on the uppermost top of the basal skeleton as a continuous process. Based on long term stainings with Ca^{2+} -chelating fluorochroms (calein,

chlorotetracyclines) the growth rate of this sponge is extremely low with ca. 50-100µm/a. The skeletal formation takes places outside the sponge, within a narrow zone (300-500 mm) between the basopinacoderm and the mature basal skeleton. The sponge produces thread-like folded templates (spaghetti fibres) of 0,5-2 µm size, the shape controlling insoluble organic matrix. These templates become mineralized in a first step as MgCO₃, then are stretched. A soluble organic matrix is also secreted, and remains are included inside the mineralized skeleton. This organic matrix consists of in a complex mixture containing small very acidic proteins (5, 13, 31 KD; 40% Asp and Glu and therefore most probably Ca²⁺ -binding) and high molecular weight glycoproteins among several other organic compounds. The mature crystals are high-Mg calcites. During calcification large cells with large reserve granules (LCG) are always present in a tight connection with the basopinacoderm. These cells form also the collagenous anchor fibres. Primary tabulae are formed by a non-collagenous organic sheet. Calcification happens only when LCG cells are enriched on the organic sheet. Randomly oriented high-Mg calcite crystals are growing on the collagenous anchor fibres. The same type of the mineralization is observed within the spaces of the tabulae. This particular case of mineralization is controlled by decaying sponge tissue (ammonification). The δ¹³C values are in equilibrium with the ambient sea water and vary between +3.2 and +2.8‰. The mode of mineralization of the basal skeleton can be described as biologically induced resp. matrix mediated.

71691 <SOURCE>Zoomorphology 110: 301-311.</SOURCE>
71692 <ABSTRACT>The tissue organization of Farrea occa has been examined by light microscopy, transmission electron microscopy (TEM), and scanning electron microscopy (SEM). It was found to agree closely with the hexactinellid model established for Rhabdocalyptus dawsoni by Mackie and Singla (1983) in consisting of a thin general syncytium incorporating few discrete cellular components, several of which share membrane continuity with the general syncytium by distinctive plug junctions. The general syncytium, supported by a thin collagenous mesolamella, is specialized regionally as dermal membrane, gastral membrane, peripheral trabecular strands, and primary reticulum (R1) of flagellated chambers. Extensions of the syncytium, which lack mesolamella support, form the distinctive secondary reticulum (R2) inside chambers and a newly discovered structure, the inner membrane, which occupies the central region of flagellated chambers. The choanosyncytia are enucleate networks of collar bodies and stolons embedded in R1 and plugged into R1 and choanoblasts. The discrete cell population consists of choanoblasts and archeocytes located in the thin mesohyle space and plugged to syncytial elements, cystocytes and vacuolar cells also located in the mesohyle but lacking plug connections, and granular cell emergent on R1 and apparently not bearing plug connections. The status of scleroblast syncytia has not been solved. Large populations of rod-shaped bacteria occupy the mesohyle space; intracellular ovoid bodies, possible symbiotic prokaryotes, are common in R1 and R2. The previously unknown inner membrane probably functions to control flagellar activity on a very localized scale and to accumulate and release egesta in packages.

71704 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 135-141.</SOURCE>
71705 <ABSTRACT>Two hexactinellid sponges from the Florida Keys, Holtenia pourtalesii and H. saccus, described by O. Schmidt in 1870, were re-examined to determine their taxonomic status. Both belong to a single species which is redescribed here. The species belongs to the subfamily Rossellinae (Hexasterophora, Lyssacinosida) but cannot be included in any of the recognized genera. The genus Vazella, Gray, 1870, is reinstated to accommodate the single species, Vazella pourtalesi (Schmidt, 1870). [original abstract]</ABSTRACT>

71808 <SOURCE>Senckenbergiana maritima 19, 3/4: 149-161 [in French, with English summary].</SOURCE>
71809 <ABSTRACT>The current data concerning *Corallium rubrum* Linne 1758 allowed to identify a skeletal mineralization mode by ectodermal secretion of independent units. These elements later amalgamate by adjunction of calcitic cement. This growth process extended to all Corallidae contrasts with the regular secretion of fibro-crystals observed among the other Cnidarians. The analysis of *Corallium johnsoni* Gray 1860 proves that this interpretation can not be applied in every case. Indeed, the axial skeleton of this less common Corallidae shows two successive mineralization stages: the first one, brief and fibrous and the second one, most important, composed of radial cylindrical units associated with groups of lamellar elements.</ABSTRACT>

71834 <SOURCE>Journal of sedimentary Petrology 53, 3: 779-786.</SOURCE>
71835 <ABSTRACT>Soft rubber tumbling barrels, some with screen windows, were used to simulate natural abrasion of coral branches. Tumbled for equal times, sealed barrels produced more sediment from coral branches than barrels with windows, and dead coral produced more sediment than live coral. Tumbled dead coral produced a gravel mode (2-4 mm) of fragmented barnacles and a sand mode (0.2 mm) of coral. Tumbled live coral produced similar results but lacked barnacles. Time series tests of

1-1000 min. showed that closed barrels produced increasingly greater percentages of carbonate mud and increasingly finer sand grain-size modes. Tumbling barrels with screen windows yielded particles of unchanging size through the same intervals. Natural sediment with broken coral branches contained coral sand most abundantly between 0.125-0.250 mm, which is the same as produce: by tumbling dead coral in barrels with screen windows. Strong grain -size modes at 0.2 mm produced by sonification and tumbling of live and dead coral and sealed and screen-window barrels support the Sorby Principle of skeletal breakdown. 71846 <TITLE>Carbon and oxygen isotope fractionations in Scleractinian corals.</TITLE>

71847 <SOURCE>Earth Science Reviews 19: 51-80.</SOURCE>

71848 <ABSTRACT>The present theories on the fractionation of stable isotopes in scleractinian corals are critically discussed in the light of data available on primary productivity, respiration and stable isotope chemistry. These data support a model of fractionation in which the carbon and oxygen isotopes are decoupled. Calcification occurs from a reservoir of carbon dioxide derived from both organic and inorganic sources. Photosynthesis preferentially fixes ¹²C and thereby leaves behind ¹³C. Increases in the rate of photosynthesis therefore also enrich the carbon isotope ratio of the skeleton. From theoretical considerations, photosynthesis has little effect on the oxygen isotope ratio of the skeleton, a fact confirmed by available data. The process of respiration adds depleted carbon and oxygen to the calcification reservoirs. The varying correlations between carbon and oxygen isotopes seen in hermatypic corals are caused by changes in the relationship between photosynthesis and respiration at different geographical localities. The isotopic compositions in the skeletons of non-zooxanthellate corals, which show a consistent positive correlation, can also be explained by the above scenario. (Original summary) </ABSTRACT>

71872 <TITLE>Reef-building properties of Tubastraea micranthus (Scleractinia, Dendrophylliidae), a coral without zooxanthellae.</TITLE>
71873 <SOURCE>Mar. Ecol. Prog. Ser. 20: 93-99.</SOURCE>
71874 <ABSTRACT>One characteristic of reef-building corals is a skeletal strength sufficient to endure hydrodynamic stress. Porosity, compressive and bending strength, elastic modulus and resistance to abrasion were measured in the reef-inhabiting colonial dendrophylliids Tubastraea micranthus and T. aurea and in the acroporids Acropora palmata and A. cervicornis. Dendrophylliids are devoid of zooxanthellae, acroporids possess zooxanthellae and are well recognized reef-builders. The mechanical properties of T. micranthus colonies, collected in Philippine reefs, equal or even surpass those of the acroporids, which rank at the high-strength end of the porosity/strength continuum. Skeletal strength and colony form set out T. micranthus as a primary framework-builder (sensu Goreau 1963), corroborating field observations on Philippine reefs. Therefore the conventional affiliation of T. micranthus to the **athermatypic** category (sensu Wells 1933) is not functionally correct. The respective data of T. aurea, however, show that this species has little significance as a reef-builder.</ABSTRACT>

71912 <SOURCE>Senckenbergiana lethaea 82, 1: 125-130.</SOURCE>

- 71913 <ABSTRACT>The scleractinian *Manicina areolata* is a common coral on Caribbean hard and soft substrata and was studied at Lee Stocking Island (Exuma Cays, Bahamas). It is not only found in reefal areas but also in bioclastic sand with seagrasses. The meandroid coralla typically grow to sizes of 2 to 10 cm and are morphological variable. Growth form can vary from conical with round to oval cross-section to turbinate forms with few meanders and flat oval cross-section. The conical morphotype is usually attached to hard substratum, while the turbinate morphotype tends to live unattached, usually upright, in soft substratum. In infratidal areas, both attached and unattached turbinate forms were found in close vicinity, however, conical attached forms were rare. Habitats with sandy softgrounds, where free-living turbinate morphotypes were common, were influenced by strong tidal currents with concurrent danger of burial or disorientation of the coralla. Therefore, strategies are necessary for the coral to remain in the upright position. Besides a high self-cleaning potential (Fabricius 1964), the colony shape itself leads to passive cleaning and self-righting, which is achieved by the flat-turbinate morphology of the corallum, with a concave side and a flat to slightly convex opposite side, under high current speeds. The concave side, and particularly the median lobes formed by many meandroid coralla, are the critical morphological factors. Particularly the grooves formed inbetween the lobes channel currents in a way that scour underneath the coral and drag produced by the lobes act together to allow passive self-righting.</ABSTRACT>

71963 <TITLE>Debating phylogenetic relationships of the scleractinian *Psammocora*: molecular and morphological evidences.</TITLE>
71964 <SOURCE>Contributions to Zoology 76, 1: 35-54.
<http://www.repository.naturalis.nl/record/217424></SOURCE>
71965 <ABSTRACT>The phylogenetic relationships of the scleractinian genus *Psammocora* with the other genera traditionally included in the family Siderastreidae and some Fungiidae are assessed based on combined skeletal and molecular data. *P. explanulata* differs from the other examined congeneric species (*P. contigua*, *P. digitata*, *P. nierstraszi*, *P. profundacella*, *P. superficialis*, and *P. stellata*) in possessing interstomatous septa between adult corallites, costae, and in having continuous buttress-like structures joining septal faces (i.e., *fulturae*) which typically occur in fungiids. These characters are shared with *Coscinaraea wellsi* but not with the remainder of the examined siderastreids (the congeneric *C. columna*, and *Anomastrea irregularis*, *Horastrea indica*, *Pseudosiderastrea tayamai*, *Siderastrea savignyana*) whose septa are interconnected by typical synapticulae. Most of the examined species form septa with distinct transverse groups of centers of calcification, a biomineralization pattern typical of the Robusta clade. The observations on skeletal structures corroborate the results of the ITS2 and 5.8S molecular phylogeny. *C. wellsi* and *P. explanulata* are phylogenetically very close to each other and show closer genetic affinity with the examined Fungiidae (*Halomitra pileus*, *Herpolitha limax*, *Fungia paumotensis*, and *Podabacia crustacea*) than with the other species in the genera *Psammocora* and *Coscinaraea*, or with any other siderastreid. Our results show that neither *Psammocora* nor *Coscinaraea* are monophyletic genera. The high genetic distances between the species of Siderastreidae, especially between *Pseudosiderastrea tayamai* and *Siderastrea savignyana* on one side and the other genera on the other, suggest a deep divergence in the phylogenetic structure of the family.</ABSTRACT>

71976 <TITLE>Environmental controls on corallite morphology in the reef coral *Montastrea annularis*.</TITLE>
71977 <SOURCE>Bulletin of Marine Science 80, 135/75 : 233-260.</SOURCE>
71978 <ABSTRACT>Scleractinian reef-coral species display high phenotypic

plasticity in skeletal morphology. Understanding environmental and physiologic controls on this variation is essential to explaining the distribution and abundance of coral species as well as understanding their susceptibility to pollution and global climate change. Here we assess phenotypic plasticity in the corallite morphology of genetically determined colonies of *Montastraea annularis* s.s. (Ellis and Solander, 1786) by analyzing the three-dimensional morphology of calical surfaces and the two-dimensional corallite morphology represented in transverse thin sections. Samples were collected along gradients of seawater depth and coastal influence on the island of Curacao, Netherlands Antilles, and additionally compared to *M. annularis* and two closely related species, *M. franksi* (Gregory, 1895), and *M. faveolata* (Ellis and Solander, 1786), collected from Panama. Significant phenotypic plasticity was found between seawater depths and localities of Curacao, as well as between the two geographic regions. Morphologic characters associated with calical surfaces were significantly more plastic than characters preserved in transverse thin sections. While characters preserved in thin section were more successful at classifying the three closely related species, characters associated with calical surfaces provide a basis for interpreting the adaptive significance of the observed differences between these three species. 71989 <TITLE>High resolution synchrotron radiation studies on natural and thermally annealed scleractinian coral biominerals.</TITLE>

71990 <SOURCE>Journal of Applied Crystallography 40, 1: 2-9.</SOURCE>

71991 <ABSTRACT>The structural phase transition from aragonite to calcite in biogenic samples extracted from the skeletons of selected scleractinian corals has been studied by synchrotron radiation diffraction. Biogenic aragonite samples were extracted en bloc without pulverization from two ecologically different scleractinian taxa: *Desmophyllum* (deep-water, solitary and azooxanthellate) and *Favia* (shallow water, colonial, zooxanthellate). It was found that natural (not pulverized) samples contribute to narrow Bragg peaks with d/d values as low as 1×10^{-3} which allows the exploitation of the high resolution of synchrotron radiation diffraction. A precise determination of the lattice parameters of biogenic scleractinian coral aragonite shows the same type of changes of the a, b, c lattice parameter ratios as that reported for aragonite extracted from other invertebrates [Pokroy, Quintana, Caspi, Berner & Zolotoyabko (2004). *Nat. Mater.* 3, 900-902]. It is believed that the crystal structure of biogenic samples is influenced by interactions with organic molecules that are initially present in the biomineralization hydrogel. The calcite phase obtained by annealing the coral samples has a considerably different unit-cell volume and lattice parameter ratio c/a as compared with reference geological calcite and annealed synthetic aragonite. The internal strain in the calcite structure obtained by thermal annealing of the biomineral samples is about two times larger than that found in the natural aragonite structure. This effect is observed despite slow heating and cooling of the sample.</ABSTRACT>

72003 <SOURCE>Senckenbergiana biologica 71, 4/6: 369-429. [in German]</SOURCE>
72004 <ABSTRACT>In Espers Werk "Die Pflanzenthiere" (Bibliographie s. Grasshoff & Scheer, 1991) stellen die Steinkorallen mit 74 abgehandelten Arten einen gewichtigen Teil dar. In Verbindung mit der Sammlung, die jetzt im Senckenberg-Museum aufbewahrt wird, wurden diese Arten kritisch ueberpruft. Zum grossen Teil waren sie anhand der guten Abbildungen schon in der bisherigen Literatur unstrittig und klar identifiziert, fur eine ganze Reihe jedoch erbrachte die jetzige Ueberpruefung erst eine Klarung. Nur wenige, namlich 8 Arten, müssen auch heute noch als nicht gedeutet oder aus anderen Grunden als nomina dubia gelten. Esper stellte alle Steinkorallen zu der Gattung Madrepora. Wegen der durch die septen sternformig gekammerten Kelchoffnungen nannte er sie "Sternkorallen", ein Name, der spaeter kaum mehr benutzt und ganzlich durch "Steinkorallen" ersetzt wurde. Wie auch bei anderen der damaligen Gattungen (Esper nannte sie "Geschlecht", die Art nannte er "Gattung") waren die Zuordnungen nicht immer klar, zwei Steinkorallen-Arten behandelte Esper unter Millepora, und 5 von ihm zu Madrepora gestellten Arten sind keine Steinkorallen. Esper hat in der Gattung Madrepora 72 Arten beschrieben und auf 100 Tafeln abgebildet, zwei weitere Steinkorallen-Arten behandelt er unter Millepora, namlich Millepora Nr. 5 und 11, hier im systematischen Teil die Nr. [73] und [74]. Von diesen 74 Arten sind 25 Erstbeschreibungen, davon sind nach heutiger Kenntnis neun Arten Synonyme und drei nomina dubia. Fünf Arten sind keine Steinkorallen, Espers Nummern 15, 30, 34, 45, und eine bei Esper ohne Nummer, hier Nr. [72]; insgesamt sind somit in Espers werk 69 Steinkorallen Arten (darunter eine fossile) behandelt und auf 97 Tafeln in 121 Exemplaren abgebildet. [part of original introduction]</ABSTRACT>

72015 <TITLE>Systematics of the Coral Genus Acropora: Implications of New Biological Findings for Species Concepts.</TITLE>
72016 <SOURCE>Annu. Rev. Ecol. Syst. 25: 237-262.</SOURCE>
72017 <ABSTRACT>The large coral genus Acropora occurs throughout the world 's reefs and is potentially a model for evolution and development of modern reef faunas. New research including breeding trials and genetic analyses of sympatric populations of Acropora and other corals is suggesting misalignments of breeding, morphological and genetic boundaries such that species limits may be sometimes narrower, sometimes broader, than presently perceived. Ongoing biogeographic and phylogenetic analyses are reexamining coral species in space and time and generating hypotheses about the origination of species. Synthesis of new findings from these research areas with preliminary insights from molecular data on species boundaries and phylogenies is allowing assessment of the current taxonomic framework of Acropora and of the order Scleractinia. The fact assumption that currently defined coral species encompass biological, evolutionary, and phylogenetic species

- concepts may be unfounded.</ABSTRACT>

- 72056 <ABSTRACT>Morphometric data for two commonly known living "species " of Montastraea are reanalyzed using cluster and canonical discriminant analysis to search for morphologic discontinuities that could correspond with morphotypes recently recognized by neontologists on the basis of behavioral and electrophoretic evidence. The samples were collected at four environmentally distinct reef habitats near Discovery Bay, Jamaica. The characters consist of linear distances and counts made on several corallites within each colony. Despite the lack of polymodality in univariate histograms, the multivariate results show two distinct morphs in M. "annularis" and three in M. "

- cavernosa". The character complexes which best distinguish these morphs are closely associated with corallite size and spacing and with number of septa, and are also found to vary among "species" and among habitats within morphs. When environmental variation is examined separately within each morph, patterns emerge which are more consistent with variation in environmental factors than those found in previous research, and thus offer added promise for the use of skeletal morphology in interpreting past environments. Patterns of environmental variation within morphs of the same "species" are similar, although different complexes may be involved within morphs of different "species", due to differences in nutritional energetics. As shown using the Neogene species *M. limbata* as an example, similar patterns can be used to detect relative differences in sedimentation and light intensity among habitats.</ABSTRACT>

72067 <TITLE>Phenotypic corallum variability in Recent mobile reef corals.</TITLE>
72068 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 263-272. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
72069 <ABSTRACT>Among free-living reef corals a distinction is made between those that are loose and potentially mobile, and those that live partly buried in soft substratum, here defined as "semi-buried". A coral may become loose by (1) detachment from its substratum or by clonopary; (2) fragmentation by autotomy or traumatic breakage; (3) overgrowing its substratum. Most reef corals programmed to become loose are able to exhume and to right themselves, and to disperse over the bottom. The phenotypic corallum variability of mobile species is related to their (1) developmental history, (2) fission and fusion, and (3) habitat. Environmental parameters that may affect corallum shape are (1) light intensity, (2) sedimentation, and (3) turbulence; this may be reflected in (1) corallum convexity, (2) thickness, (3) number of mouths, and (4) coarseness of septocostal ornamentation. Some ecophenotypes may have adaptive significance with regard to sediment-shedding and mobility.</ABSTRACT>

72094 <SOURCE>Helgolaender Meeresunters 45: 423-443.</SOURCE>
72095 <ABSTRACT>The organization of the zooxantellate scleractinian coral *Leptoseris fragilis* was studied. The architecture of the corallite and the histology of the polyparium were analysed for adaptations that enable efficient capture and retention of suspended particles which would increase energy supply. The data indicate that the gastrovascular system of *L. fragilis* is not a blind but a flow-through system. Water entering the coelenteron through the mouth leaves the body not only through the mouth but also through microscopic pores (D 1-2 µm) which are located near the crest of the sclero-septa in the oral epithelia. Irrigation is achieved by flagellar and probably also by muscular activity. This type of filtration enables *L. fragilis*, which lacks tentacles, to utilize suspended organic material including bacteria. The supposed suspension feeding in combination with effective photoadaptations (presented in former communications) seems to be the basis for the survival of *L. fragilis* in an extreme habitat (between -95 and -145m) and for its successful competition with other scleractinian species provided with larger catching surfaces, and with other invertebrates depending on filter feeding.</ABSTRACT>

72119 <TITLE>*Gardinieria* - a scleractinian living fossil.</TITLE>
72120 <SOURCE>Acta Palaeontologica Polonica 41, 4: 339-367.</SOURCE>
72121 <ABSTRACT>The basic architecture (Bauplan) and microstructure of the skeleton of Recent *Gardinieria* are noticeably different from those of most other modern scleractinians. The wall of the *Gardinieria* skeleton is entirely epithecate (non-trabecular), while in the majority of modern scleractinia the epitheca is either absent or added to the main wall which usually is of trabecular nature. These different patterns of theca formation reflect significant anatomical differences in the peripheral parts of the polyp. The Bauplan of *Gardinieria* pattern, exceptional in the modern scleractinian fauna, was widespread among early Mesozoic corals, particularly among the Triassic

protoheterastraeids. Similar skeletons also occur in some late Palaeozoic rugosans (e.g., polycoeliids). Zardinophyllum zardini, an aberrant Triassic scleractinian coral, with a supposed rugosan septal insertion, supports the hypothesis of the rugosan origin of the Scleractinia. [original abstract]

72134 <ABSTRACT>The nutrition and the growth of zooxanthellate, hermatypic Scleractinians in the Gulf of Aqaba was studied. Growth rates of entire colonies are species-specific and depend upon water depth. Annual skeletal mass increment correlates best with the seasonally changing light regime (photosynthesis by the zooxanthellae). The supply with particulate food (seston, sediment) during the year has no marked effect on carbonate production. Zooxanthellae of different origin (various species, different depths) showed photoadaptations toward light limitation. However, the zooxanthellae of two species studied showed no genetic heterogeneity (enzyme electrophoresis). Thus the different photosynthetic features base on phenotypic plasticity. Adaptations improving phototrophic and heterotrophic food supply were detected. The biomass, the pigmentation, the spectrum of assimilates and the productivity of endolithic green algae was studied. The productivity is low and reaches 3-8% of that of the zooxanthellae under corresponding light conditions. The utilization of endolithic photoassimilates by the coral's metabolism could be proven. Endolithic algae are - like zooxanthellae - involved in recycling processes within the reefal food web. Although the annual availability of light for scleractinians in the Gulf of Aqaba is considerably reduced in comparison to low latitude reefs, the corals show luxurious growth. Besides a multitude of other factors, the luxurious growth could speculatively be due to a lack of temperature stress.</ABSTRACT>

</TITLE>
72146 <SOURCE>Facies 36, 1: 189-194.</SOURCE>
72147 <ABSTRACT>Soluble organic matrices extracted from aragonitic skeletons produced by recent zooxanthellate and non-zooxanthellate scleractinian

corals were studied after suitable hydrolyses, by FIPLC chromatographies allowing characterization of their amino acid and monosaccharide compositions. Clear compositional differences can be correlated with the symbiotic or non-symbiotic character in both proteic (via Asp, Glu, Ala and Ser) and glucidic phases of soluble matrices (via GalN, GlcN and Gal), providing new criteria to assess the impact of photosynthetic metabolism on skeletal features of scleractinian corals.</ABSTRACT>

72158 <TITLE>Plasticity of the Scleractinian Body Plan: Functional Morphology and Trophic Specialization of Mycedium elephantotus (Pallas, 1766).</TITLE>

72159 <SOURCE>Facies 39, 1: 227-241.</SOURCE>

72160 <ABSTRACT>Morphological, histological and behavioral features indicate that Mycedium elephantotus, a zooxanthellate scleractinian species without tentacles, is well adapted for utilizing suspended organic matter for nutrition. The colonies are composed of vertically growing fan-like plates and can reach diameters of more than 1 m in depths below 20 m. The external body surface is coated with a mucus layer (cuticle) which enables the acquisition and accumulation of suspended organic material. The mucus-entangled particles pass to the mouth openings by gravitational transport assisted by water movement. In experiments the corals were able to discriminate between suspended food and mineral particles. Both types of particles were rapidly entangled in fine mucus nets or filaments. Mineral particles were never ingested and instead tumbled down the inclined skeletal plates. In contrast, food particles were actively incorporated when the mucus filaments accidentally touched the stomodaea during the downward gliding. The food-enriched mucus filaments were either transported by ciliary activity into the coelenteron or were sucked into the body cavities by decreasing pressure in the coelenteron caused by contraction of longitudinal, mesenterial muscles. The discriminative reactions to mineral or food particles are probably based on the release of different types of mucus. Nematocysts are infrequent in the oral epidermis, indicating that the capture of living prey plays a subordinate role in nutrition. The mesenterial filaments, in contrast, are densely packed with large nematocysts. Storage products were piled up within the tissues of gastral pockets. The adaptations of Mycedium elephantotus for using suspended food particles may explain the particularly high abundance of this species between ca. 20 and 40 m depth on a steeply inclined fore-reef slope in the Gulf of Aqaba (Red Sea). The evidence indicating the importance of heterotrophic fueling to M. elephantotus is supported by carbonate production rates which are, in contrast to that of many other zooxanthellate scleractinian species, almost constant at depths between 5 and 40 m and which are unaffected by varying light regimes over the year, suggesting that the reduced phototrophic contribution by the zooxanthellae is compensated by mucus suspension feeding.</ABSTRACT>

72171 <TITLE>A new type of symbiosis: Heterocyathus japonicus (Cnidaria: Scleractinia) living on Fissidentalium vernedei (Mollusca: Scaphopoda).</TITLE>
72172 <SOURCE>Zoologische verhandelingen 323: 319-340.</SOURCE>
72173 <ABSTRACT>After introductory remarks on the solitary coral genera Heterocyathus and Heteropsammia, commonly known to be symbiotic with a sipunculan inhabiting a gastropod shell, Heterocyathus japonicus is redescribed in detail. It occurs from Taiwan to northern Honshu, Japan. It is the first of these symbiotic corals to be found in association with an alternative partner, living specimens of the large scaphopod Fissidentalium vernedei. The coral always occupies the apical end of the shell, the part that protrudes from the sediment. It is thus preserved from being buried and is maintained in an upright position (the same advantages it also gets when its partner is a sipunculan). On live F. vernedei, H. japonicus incrusts a manganese rich black mineral coating that characterizes the exposed, apical part of the shell. It is speculated about which factors may cause coral larvae to associate with the partner (sipunculan squatting a shell, scaphopod in its own shell).</ABSTRACT>

72184 <TITLE>Microstructural and physico-chemical characterization of " centers of calcification" in septa of some Recent scleractinian dorals </TITLE>
72185 <SOURCE>Pal. Zeitschr. 72, 3/4: 257-270.</SOURCE>
72186 <ABSTRACT>In order to define the value of the concept of "center of calcification", an attempt has been made to collect microstructural, physical, and chemical data from these particular structures. In each of the fifteen species studied, these data are compared with similar characteristics observed in the surrounding fibrous tissue. Results lead to a paradoxical conclusion. Although the existence of centers of calcification is sometimes denied, they have been evidenced by various techniques in septa of all the studied species, that belong to various families. Thus, "centers of calcification" appear to be a basic component in the development of corallian septal architecture. But taking into account their microstructural and chemical peculiarities allows to introduce some changes in the currently admitted view concerning their role in skeletogenesis of Scleractinia.</ABSTRACT>

72251 <ABSTRACT>L'étude de nombreuses Montlivaltia provenant de différentes régions du globe permet de préciser la constitution de leurs septes: ceux-ci présentent une structure axiale formée par la soudure de trabecules fibreuses, uniaxiales et de couches laminaires latérales. La même composition septale est reconnue chez Stereophyllia All. (Bathonien) et chez Cyclostraea All. (Cénomaniens). La permanence d'une telle constitution durant le Jurassique et le Crétacé fait croire à l'existence d'un groupe naturel qui devrait être introduit dans la Systématique. La structure septale de Fungia actuelle se révèle semblable à celle des genres cités ci-dessus.</ABSTRACT>

72275 <TITLE>Sediment rejection by recent scleractinian corals: a key to palaeoenvironmental reconstruction.</TITLE>
72276 <SOURCE>Geol. Rundschau 61, 2: 598-626.</SOURCE>
72277 <ABSTRACT>26 of the 59 living species of scleractinian corals found in western Atlantic and Caribbean waters, less than 68 meters deep, and two fungiid genera from the Pacific, are analysed in terms of their behaviour, sediment rejecting properties, functional, morphology and distribution patterns. The contrasting behaviour and skeletal structure of the two solitary fungiids provides evidence for the construction of

a theoretical mechanical model which is applied to the subsequent interpretation of the more complex colonial reef corals from the Atlantic province. Regional distribution patterns, growth forms and calical orientations of the Atlantic species and their associated sediment types were noted in dives across transects in extreme environments in the Caribbean. Representative samples were then selected from the five functional ecological niches in the Florida keys, and subjected to inundations of sized and painted carbonate sand particles in the laboratory. The coral was filmed before the sedimentary influx, on impact and during rejection. The skeletons were then extracted and dissected to construct a mechanical model compatible with their behavioural functions. There are four means of sediment rejection: distension by the stomodeal up-take of water, tentacular action, ciliary beat, and mucus entanglement. Differences in sediment rejection are ascribed to two factors (1) variations in the polyps distensional capacity, and (2) the geometry of the calice. A theoretical model of characteristic scleractinian distribution patterns on an Atlantic patch reef mirrors regional distribution patterns. The sediment rejecting experiments are used as additional evidence for interpreting other behavioural activities of greater consequence e.g. food gathering and the removal of excrement. Theoretical models are described for the relationship of calical form to polypal function and calical orientation to distribution patterns on the corallum; and also variations in growth form. Ecological distributions, in local patch reef and regional occurrences, are outlined in terms of the recent scleractinian corals of the Atlantic province. These models are tested against some rugose and tabulate coral distributions in the Irish Carboniferous.

(Ellis & Solander) and Siderastrea siderea (Ellis & Solander).
</TITLE>
72354 <SOURCE>J. Exp. Mar. Biol. Ecol. 39: 25-54.</SOURCE>

- 72355 <ABSTRACT>[…] although *M. annularis* shows more plasticity than *S. siderea*. both species have highly plastic phenotypes. A large number of characters describing the architecture of corallites respond to environmental factors such as light intensity, sedimentation rate, water activity, and food availability. The most plastic characters in *M. annularis* describe coenosteal features and the thickness of thecae. The most plastic characters in *S. siderea* describe the thicknesses of thecae, septa, and columellae. * This study suggests that phenotypic plasticity is an important species attribute in scleractinians and may be a significant mechanism in controlling the distribution and abundance of scleractinians on reefs. - 72368 <ABSTRACT>The calcification processes of the cool temperate coral *Balanophyllia regia* have been studied during the settlement and metamorphosis of planulae larvae into polyps. Ultrastructural studies of the fully developed and settled post-larval stages have implicated one of the gland cell types in the secretion of an organic matrix prior to skeletal growth. Qualitative X-ray analytical studies using the scanning transmission electron microscope (STEM) have supported these observations: calcium was detected in this organic substance after it had been secreted into the 1-3µm wide space between the skeletogenic epithelium and the substrate. Thirty-six hours later X-ray mapping of this matrix showed that high levels of calcium were more easily detected within crystal-like profiles than in the surrounding areas. - 72381 <ABSTRACT>Accurate determinations have been made of the distribution of uranium in fresh and diagenetically altered coral skeletons occurring both naturally and grown under a variety of experimental conditions. Whereas live coral skeletons are homogeneous in uranium distribution, dead skeletons show homogeneities relating to lithothamnioid algal encrustations and endolithic sponges. In the analyses of over 100 live coral skeletons, no zonal uranium distributions, described by previous workers, were found. In skeletons, free from organic material, uranium was found to exchange readily with the coral skeleton and/or to be precipitated along trabeculae axes and skeletal margins. Bioeroded specimens contained higher uranium concentrations than freshly formed aragonite; they were similar to fossil coral skeletons used by previous

- researchers for uranium series dating. [original abstract] </ABSTRACT>

72392 <TITLE>The name game: morpho-molecular species boundaries in the genus Psammocora (Cnidaria, Scleractinia).</TITLE>
72393 <SOURCE>Zoological Journal of the Linnean Society 160: 421-456.</SOURCE>
72394 <ABSTRACT>The morphometric and molecular boundaries between twelve Psammocora (Cnidaria, Scleractinia) nominal species were addressed. The type specimens of Psammocora haimiana Milne-Edwards & Haime 1851, P. togianensis Umbgrove 1940, P. folium Umbgrove 1939, P. digitata Milne-Edwards & Haime 1851, Maeandroseris australiae Rousseau 1854, P. samoensis Hoffmeister 1925, P. superficialis Gardiner 1898, P. profundacella Gardiner 1898, P. nierstraszi van der Horst 1921, P. verrilli Vaughan 1907, and P. albopicta Benzoni 2006, were analysed together with specimens from museum collections, including those depicted in widely cited taxonomic descriptions, and material collected for this study in different parts of the Indo-Pacific. Morphometric analyses of the dimensions of skeletal structures allowed the identification of groups of specimens with similar morphologies. Congruency between these groups and current species whose synonymies and descriptions were found in recent taxonomic references was, hence, investigated and the species revised. Finally, the phylogenetic relationships of a representative subset of specimens were reconstructed based on rDNA and COI, thus allowing a direct link between morphologic and genetic information. Incongruence between type of morphology and literature descriptions was evidenced for some widely recognised species. Based on this integrated approach, five species were unambiguously identified. 72405 <TITLE>Skeletal growth, ultrastructure and composition of the azooxanthellate scleractinian coral Balanophyllia regia.</TITLE>
72406 <SOURCE>Coral Reefs 29, 1: 175-189.</SOURCE>
72407 <ABSTRACT>The biomineralization process and skeletal growth dynamics of azooxanthellate corals are poorly known. Here, the growth rate of the shallow-water dendrophyllid scleractinian coral Balanophyllia regia was evaluated with calcein-labeling experiments that showed higher lateral than vertical extension. The structure, mineralogy and trace element composition of the skeleton were characterized at high spatial resolution. The epitheca and basal floor had the same ultrastructural organization as septa, indicating a common biological control over their formation. In all of these aragonitic skeletal structures, two main ultrastructural components were present: "centers of calcification" (COC) also called rapid accretion deposits (RAD) and "fibers" (thickening deposits, TD). Heterogeneity in the trace

element composition, i.e., the Sr/Ca and Mg/Ca ratios, was correlated with the ultrastructural organization: magnesium was enriched by a factor three in the rapid accretion deposits compared with the thickening deposits. At the interface with the skeleton, the skeletogenic tissue (calicoblastic epithelium) was characterized by heterogeneity of cell types, with chromophile cells distributed in clusters regularly spaced between calicoblasts. Cytoplasmic extensions at the apical surface of the calicoblastic epithelium created a three-dimensional organization that could be related to the skeletal surface microarchitecture. Combined measurements of growth rate and skeletal ultrastructural increments suggest that azooxanthellate shallow-water corals produce well-defined daily growth steps. [original abstract]

72418 <TITLE>Strontium-86 labeling experiments show spatially heterogeneous skeletal formation in the scleractinian coral *Porites porites*.</TITLE>
72419 <SOURCE>Geophysical Research Letters 36, L04604.</SOURCE>
72420 <ABSTRACT>This paper presents the results of an effort to label calcium carbonates formed by marine organisms with stable isotopes to obtain information about the biomineralization processes. The growing skeleton of the scleractinian coral *Porites porites* was labeled three times with enhanced abundances of ⁸⁶Sr. The distribution of ⁸⁶Sr in the skeleton was imaged with the NanoSIMS ion microprobe with a spatial resolution of 200 nm and combined with images of the skeletal ultra-structure. Importantly, the distribution of the ⁸⁶Sr label in the *P. porites* skeleton was found to be strongly heterogeneous. This constrains the physical dimensions of the hypothetical Extracellular Calcifying Fluid (ECF) reservoir at the surface of the growing skeleton, which is implicit in most geochemical models for coral biomineralization. These new experimental capabilities allow for a much more detailed view of the growth dynamics for a wide range of marine organisms that biomineralize carbonate structures. 72446 <ABSTRACT>Recruitment of juvenile scleractinian corals to natural calcium carbonate settlement plates varied seasonally and annually on 4 vertically separated reef front sites during a 3 yr study period. Early summer was the major recruiting season: of 1.470 recruits observed on 184 plates over 2 yr, 89% were in spring-summer (Oct to Feb), 8% in summer-winter (Feb to Jun) and 3% in winter-spring (Jun to Oct). The peak early summer recruitment was significantly greater in 1980-81 (32 juveniles per plate) than in 2 subsequent years (1981 - 82,9 per plate; 1982 - 83,1 per plate). 72457 <TITLE>Staghorn Corals of the World. A revision of the genus Acropora.</TITLE>
72458 <SOURCE>CSIRO Publishing; 436 pp. ISBN 9780643063914</SOURCE>
72459 <ABSTRACT>Staghorn corals (genus Acropora) are the most obvious and important corals on coral reefs throughout the world, providing much of the beauty and variety seen on the reefs. This invaluable reference tool, the first major review of Acropora in over 100 years, synthesizes all we know about the genus. It assesses all the known species worldwide, describing each in detail and illustrating the range of variability of form with habitat and geographic location. The classification, evolution and world-wide distribution of all species are reviewed and illustrated with colour plates, full page black and white plates and distribution maps. Details of the general biology of staghorn corals are discussed and illustrated. * The book is complemented by a CD-ROM, Staghorn Corals of the world: A key to Species of Acropora CD-ROM, containing a LucID-based key to all species of Acropora and a photographic database of type specimens from museums around the world.</ABSTRACT>

72471 <SOURCE>CSIRO Publishing; CD-ROM. ISBN 0643063919</SOURCE>
72472 <ABSTRACT>Coral reef workers know the importance of staghorn corals (genus Acropora) on reefs throughout the world, and will recognise the need to accurately identify the different species. They will therefore appreciate the value of this interactive key for identifying staghorn corals which has resulted from the first major review of the Acropora in over 100 years. * A simple step-by-step selection of characters will

enable the user to identify any of the 113 species of Acropora. Over 2000 photographs, micrographs and illustrations in colour and black and white are included to guide the user. Additionally there is a photographic database of the type specimens of Acropora collected from museums around the world. The CD-ROM is complemented by the book, Staghorn Corals of the world: A Revision of the Genus Acropora, which synthesizes all we know about this genus. It is an essential tool for all reef workers and coral workers around the world. </ABSTRACT>

72483 <TITLE>Matrices organiques intrasquelettiques des Scléractiniaux récifaux: Évolution diagénétique précoce de leurs caractéristiques biochimiques et conséquences pour les processus de cimentation. [in French, with English abstract]</TITLE>

72484 <SOURCE>Geobios 33, 1: 73-78.</SOURCE>

72485 <ABSTRACT>Biochemical character and properties of intraskeletal organic matrices are studied in skeleton pieces from several growth zones sampled in a 25cm long living Porites core. In experimental conditions these organic matrices exhibit an inhibitory effect on CaCO₃ precipitation which increases all along the 15-20 upper cm of the core. Parallely relative amino acid compositions are more and more enriched in aspartic and glutamic acids from the surface to the base of the core, and molecular weights of glycoprotein compounds are comparable to those of the uppermost living zone in all parts of the core except in the base. From the combination of experimental results it is concluded that the highest inhibiting efficiency of organic matrices is a consequence of quantity, the composition (Asp concentration) of organic matrices, and the preservation of high molecular weight assemblages. Consequences for cementation processes in superficial zones of coral reefs are examined. It is most probable that the diagenetic state of intraskeletal organic matrices influences the development of cements directly upon the surface of skeletal substrates, as well as the formation of diagenetic aragonite overlaying biogenic aragonite within skeletal structures. Conditions in reefal cryptic zones inhabited by sponges are discussed as a comparison with photic zones where scleractinian corals are located. [original abstract]</ABSTRACT>

72496 <TITLE>Ultrastructural controls on diagenetic patterns of scleractinian skeletons: evidence at the scale of colony lifetime.</TITLE>

72497 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 210-218.</SOURCE>

72498 <ABSTRACT>The earliest fine scale diagenetic changes in corals were investigated by comparing microstructural and ultrastructural features from the uppermost skeletal parts of living colonies with those obtained from older parts of the same specimen. In addition to its

organic mineral duality, the initial heterogeneity of the scleractinian skeleton is shown by the occurrence of a micron scale zonation within crystal fibers, resulting from incremental growth during elementary cycles of biomineralization and also by the presence of two basic structural features, calcification centers and fibers, clearly differentiated from each other. Within the species analyzed, micro and ultrastructural data reveal additional fine scale diversity related to taxonomy. At the time scale of colony life, the earliest processes of diagenesis produce a thin fringe of syntaxial aragonite cements, alteration of the incremental zonation of scleractinian fibers, and also, preferential diagenesis within calcification centers. These early modifications of coral skeletons are obviously controlled by the biological ultrastructural characteristics of scleractinian taxa and also suggest that early diagenesis does not necessarily imply drastic change in environmental conditions. 72509 <TITLE>XANES mapping of organic sulfate in three scleractinian coral skeletons.</TITLE>

72510 <SOURCE>Geochimica et Cosmochimica Acta 67, 1: 75-83.</SOURCE>

72511 <ABSTRACT>The presence and localization of organic sulfate within coral skeletons are studied by using X-ray absorption near edge structure spectroscopy (XANES) fluorescence. XANES spectra are recorded from four reference sulfur-bearing organic molecules; three amino acids (H-S-C bonds in cysteine; C-S-C bonds in methionine; one disulfide bond C-S-S-C bonds in cystine) and a sulfated sugar (C-SO₄ bonds in chondroitin sulfate). Spectral responses of three coral skeletons show that the sulfated form is extremely dominant in coral aragonite, and practically exclusive within both centres of calcification and the surrounding fibrous tissues of coral septa. Mapping of S-sulfate concentrations in centres and fibres gives us direct evidence of high concentration of organic sulfate in centres of calcification. Additionally, a banding pattern of S-sulfate is visible in fibrous part of the coral septa, evidencing a biochemical zonation that corresponds to the step-by-step growth of fibres. 72535 <TITLE>Systematics and ecology of mushroom corals (Scleractinia: Fungiidae).</TITLE>
72536 <SOURCE>Edited by the author; 471 pp., 700 figs., 11 tbls.</SOURCE>
72537 <ABSTRACT>[Unlike the majority of other reef corals, most Fungiidae do not remain attached to the bottom. Adult mushroom corals may be found on several kinds of substrata; they live on sand, rubble, dead coral or even on top of living coral. They can be found in environments where many other corals cannot live, such as lagoons, reef bases and terrigenous non-reefal bottoms. In the systematic part of this thesis, a taxonomic revision is given with descriptions of the 40 species that are presently classified with the Fungiidae (chapter 2.1). These descriptions define the material used in the other chapters. The family is divided into 51 genera, one of which, Fungia, is subdivided into seven subgenera. Three species are new to science and one is renamed because its name was already in use for another species. Furthermore, an overview of the stratigraphic distributions is given for all species. A tentative phylogenetic reconstruction down to the species level is given. The fungiidae are the first scleractinian family for which such an analysis has been undertaken. The cladogram that is provided should be considered a working hypothesis and not a sound basis for a completely revised classification. (fragment taken from extensive summary)]</ABSTRACT>

72575 <SOURCE>Smithsonian Contributions to Zoology 591: 55 pp., 10 pls.</SOURCE>
72576 <ABSTRACT>The monophyly of the Turbinoliidae is based on the unique (with the Caryophylliina) character of having its entire corallum invested with tissue, which is reflected in its well-formed costae from base to calice and its characteristically deep intercostal regions. All turbinoliids are solitary and free-living, and thus the complete investiture of its corallum might facilitate movement through or across a sandy substrate. The Turbinoliidae consists of 28 genera and 163 valid species, of which 22 genera and 49 species are extant. The earliest known turbinoliid is from the Late Cretaceous (Campanian) of Antarctica. All 28 genera are diagnosed and figured herein. The stratigraphic and geographic distributions are discussed for each genus, and a list of species known for each genus, including junior synonyms, is given. Two genera and two species are described as new: Pleotrochus, P. zibowii, Foveolocyathus, and Sphenotrochus wellsii. Peponocyathus is restricted to those species having transverse division, which requires the resurrection of Deltocyathoides Yabe and Eguchi 1932, for those species that do not reproduce by transverse division, and it also requires the synonym of Truncatocyathus Stolarski 1992. Tropicocyathus is divided into two genera, allowing the resurrection of Cyathotrochus Bourne 1905. Oryzotrochus stephensoni Wells 1959, is identified as a Turbinolia, which synonymizes Oryzotrochus and extends the stratigraphic range of Turbinolia from the Oligocene to Recent. 72587 <TITLE>Tissue damage in scleractinian and alcyonacean corals due to experimental exposure to sedimentation.</TITLE>
72588 <SOURCE>Beiträge zur Paläontologie 20: 51-63.</SOURCE>
72589 <ABSTRACT>Four South African scleractinian corals (Favia favus, Favites pentagona, Platygyra daedalea and Gyrosmilia interrupta) and four alcyonacean corals (Lobophytum depressum, Lobophytum venustum, Sinularia dura and Sinularia leptoclados) were experimentally exposed to high sedimentation conditions in the laboratory during a period of six weeks. Experimental sedimentation corresponded to the highest measured sedimentation levels on South African coral reefs, being 200 mg cm⁻²h⁻¹. Corals were monitored for tissue necroses and bleaching during the course of the experiment and histological sections were prepared after the termination of the experiment. During the experiment, tissue necroses appeared earlier and more frequently in alcyonacea than in scleractinia. Histological sections showed degeneration and necroses of epithelia and mucus-producing cells with accumulation of free mucous material in the epithelia as well as loss of zooxanthellae, was observed in three alcyonacea (Lobophytum depressum, Sinularia dura, Sinularia leptoclados). Not all parts of the alcyonacean colonies were equally affected by tissue damage and bleaching. In particular, elevated lobes and finger-like projections, which were never covered by sediment for long periods, did not exhibit

the same severe damage or bleaching as flat parts of the colonies. Scleractinia did not suffer the same amount of tissue damage as alcyonacea, no bleaching was observed. Partial necroses and degeneration of epithelia as well as changes in mucus producing cells were also observed in scleractinia. </ABSTRACT>

72613 <TITLE>High resolution Sr/Ca records in sclerosponges calibrated to temperature in situ.</TITLE>

72614 <SOURCE>Geology 32, 2: 145-148.</SOURCE>

72615 <ABSTRACT>Ratios of strontium to calcium have been analysed by laser-ablation inductively coupled plasma-mass spectroscopy (LA-ICP-MS) in a skeletal section of the sclerosponge *Ceratoporella nicholsoni*. The growth period, representative of 3 yr, was stained in the skeleton with a fluorochrome (calcein). Temperatures were recorded at 2 h intervals within the shallow cryptic reef enclosure that the sclerosponge inhabited on the northern coast of Jamaica, allowing the formulation of a direct empirical relationship between Sr/Ca and temperature. To verify this calibration, Sr/Ca ratios of two sclerosponges of the same species from depths of 67m and 136m in Exuma Sound, Bahamas, were analysed by LA-ICP-MS and compared to the temperatures from these depths over a decade prior to collection. The result is an independently verified, high-resolution empirical calibration for the temperature sensitivity of Sr/Ca ratios in the aragonite skeleton of sclerosponges from Jamaica and the Bahamas. The calibration is a first for *C. nicholsoni* and indicates that the sclerosponges are more sensitive temperature recorders than zooxanthellate corals. It represents an important step in establishing skeletal geochemistry of sclerosponges as a proxy of temperature in the upper 250m of the ocean. [original abstract]</ABSTRACT>

actuelle.</TITLE>
72640 <SOURCE>Coll. Int. CNRS 291 (Biologie des spongiaires): 283-293; Lyon.
</SOURCE>
72641 <ABSTRACT>A living fossil of the group Sphinctozoa has been
discovered in the Indian Ocean and in New Caledonia in a very cryptic
habitat of the outer slope of coral reefs. The living tissue is inside
a series of hemispherical chambers. The perforated chamber walls are
composed of aragonite and consist of a feltwork of microfibrils. In
the growing sponge, the skeleton of a new chamber appears first as an
organic matrix, which is the template for a later calcification. There
are no spicules. The histology, cytology and sexual reproduction are
compared to those of the recent Porifera. They are similar to those of
the Ceractinomorpha in the class Demospongia. * This study shows that
most fossil Sphinctozoa were relatives of Demosponges. They are
considered by the author as an order of the class Demospongia. These
sponges were devoid of spicules. Thus, the exclusion from the Porifera
of some fossil groups as Stromatopores or some Tabulates on the ground
of the absence of spicules is not valid. A new order Sphaerocoelida is
proposed for Cretaceous sponges which have the same structure, but
which have calcareous spicules and probably are homeomorphs of the
class Calcarea. A comparison is made between the 14 recent sponges
which possess a non-spicular calcareous skeleton. The large diversity
of both the skeleton and the living tissue of these sponges indicates
that their hypercalcification is an archaic character, which was
frequent in the past and which disappeared in most of the recent
sponges. [original abstract]</ABSTRACT>

72652 <TITLE>Calcification of Encrusting Aragonitic Algae (Peyssoneliaceae):
Implications for the Origin of Late Paleozoic Reefs and Cements.</TITLE>
72653 <SOURCE>Journal of Sedimentary Petrology 68, 2: 291-303.</SOURCE>
72654 <ABSTRACT>Encrusting aragonite calcareous algae of the family
Peyssoneliaceae are the largest group of calcified red algae outside
the well-known Mg calcite Corallinaceae. They are distributed

worldwide, are most heavily calcified in temperate and tropical waters, and grow as prone but arched sheets on soft mud substrates on hard rock surfaces, as extensive bridge-like networks between corals in reefs, and as concentric layers in nodules. Calcification is entirely aragonitic, species-specific and both intracellular and extracellular below the thallus as a hypobasal layer. The hypobasal layer develops outside the tissue as an encrustation of small aragonite botryoids attached to the lower surface between rhizoids, and on living plants it may exceed in thickness of the thallus. Calcification ranges from nonexistent in some cold-water forms, to thallus calcification only, to both thallus and hypobasal calcification, to species in which the thallus is noncalcified but there is a hypobasal layer of aragonite botryoids. Although the confirmed fossil range of this family extends only to the Early Cretaceous, striking similarities between these aragonitic forms and some late Paleozoic phylloid algae suggest that they may be closely related. Their ability to grow on soft mud substrates and form structures composed of irregular arched sheets with extensive pore space, as well as their brittle nature, so susceptible to fragmentation, are all characteristics of mound-forming fossil phylloid algae. The hypobasal layer of botryoidal aragonite, developed while the plant is still growing, could easily act as a nucleation site for further epitaxial submarine precipitation, thus explaining the common association of Paleozoic phylloid algae and extensive fossil-reef cements that resemble botryoidal aragonite. The presence of hypobasal botryoidal aragonite on plants with noncalcified thallus raises the possibility that some fossil-reef cements may be related to now-vanished algae.

72679 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunkel F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
72680 <ABSTRACT>Unlithified benthic microorganisms (potential stromatolites) have been identified as an important factor regulating spatial distributions of bryozoans and pioneer settlement in reefs. Skeletal adaptations and zoarial modifications of recent and fossil bryozoans provide information on competitive interactions with microbial mats. Mutualism with epizoic microorganisms also exists and is detectable in

zooidal sculptures (bryozoan microreefs). The rates of competitive and mutualistic interactions are suggested to be a tool for use in paleoecological and paleoclimatic research. Possibilities for an [applied paleontology](#); based on bryozoans as indicators for environmental stress and [artificial reef](#); studies are outlined.

72704 <TITLE>Reef-Bryozoans and Bryozoan-Microreefs - Control Factor Evidence from the Philippines and other Regions.</TITLE>

72705 <SOURCE>Facies 32: 109-144.</SOURCE>

72706 <ABSTRACT>In this paper, a preliminary concept on the interplay of local, regional and global control factors of bryozoan diversity and distribution pattern is introduced. Recent bryozoans from the Philippines, New Zealand and the Gulf of Aqaba are compared to the selected fossil specimens from the Oxfordian and Santonian. Reef bryozoan skeletons are studied in order to separate local control within the substrate-water interface from regional control. The latter originate mainly from the transport function of the water column (e.g. sediment load, wave energy, vagile predators). This is true especially for erect (tree-like) and massive (multilaminar) bryozoans which are subjected to the dynamics of the water body in the littoral area. This regional control, affects simultaneously several structural and substrate zones of a reef. Early life history of vertically growing reef bryozoans reflect local control, while older zoarial structures reflect the signals of regional influence. Three types of multiseriate nodular bryozoans are cited: self-overgrowing sheets ([S-Nodule](#); derived from [S-Sheet](#)); circumlaterally budding colonies ([C-Nodules](#)); and fungiform bryozoans. 72769 <TITLE>Studies in the Reef-dwelling Cnidarian Cassiopea spp.: RF-amide positive elements of the nervous system at different stages of development.</TITLE>
72770 <SOURCE>Beiträge zur Paläontologie 20: 21-29.</SOURCE>
72771 <ABSTRACT>The nervous system and its alterations in various stages of

development has been investigated in *Cassiopea andromeda* and *C. xamachana* using immunocytological detection of RF-amide (Arg-Phe-amide) related neuropeptides which are known to occur generally in cnidarians. Immunoreactive neurons, visualized by epifluorescence in whole-mount preparations, were found in all stages of development investigated so far (asexual buds, metamorphosing buds, polyps, strobilae, ephyrae, and young medusae), except for bud anlagen developing at the parental polyps. Congruent results were obtained in the two species, also with respect to non-specific immunostaining of some ectodermal gland cells and nematocytes. Immunoreactive nerve nets were observed in tentacles and the hypostome of the polyp stages, in the manubrium and subumbrella of the ephyra, and also in the exumbrella of the young medusa. Apicobasal tracts paralleling septal muscles of the polyps calyx were seen only during bud-to-polyp metamorphosis. Condensations of anti-RF-amide positive nerve cells occurred in the scyphistoma at the margin of the hypostome, and as a prominent nerve ring below the tentacle bases, connecting the individual tentacular nerve nets. Dense nerve cell populations were noticed next to the rhopalia in ephyrae and in young medusae, a connecting circular tract at the umbrellar margin was detectable only in the latter. An apparent lack of anti-RF-amide positive neurons was recorded in the free-swimming buds, and in some domains of both the polyp and the young medusa. We suggest that the immunoreactive nerve elements in *Cassiopea* spp. reported on here represent only a subset of neurons within a more complex nervous system.

72796 <SOURCE>Biomineralization Research reports 7: 37-45.</SOURCE>

72797 <ABSTRACT>Study with the scanning electron microscope shows basic differences in microstructure between several groups of coelenterates. The present report deals with skeletal microstructure and microarchitecture in *Millepora* (*Milleporina*), *Stylaster*, *Errina*, and *Distichopora* (*Stylasterina*) among hydrozoans. In the octocorals (*Anthozoa*) details are presented of *Tubipora*, *Helipora*, and the gorgonian *Eunicea*. * The aragonitic milleporines and stylasterines have similarities to the scleractinian skeleton and a similar ectodermal model of biocrystallization can be employed to explain observed skeletal characteristics. The three groups are unified by the presence

of a spherulitic type of crystallization, although the consistency of the proteinaceous templating material is obviously different for different groups. * Those coelenterates with mesogloal secretion of spicules or skeletal crystallites are all unified by needle-like crystallites of approximately the same size, each oriented with its long axis only slightly emergent from the surface of skeletal elements. The octocorals examined here each show such structure. Heliopora, in addition to this last has a different, more milleporine-like structure in the first-formed parts of its skeleton.</ABSTRACT>

72822 <SOURCE>Science 250: 1244-1248.</SOURCE>

72823 <ABSTRACT>[Recent and subfossil calcareous structures resembling cystose and subclathrate Paleozoic stromatoporoids have been discovered in an alkaline crater lake in Indonesia. The structures are produced by mats of coccoid cyanobacteria. Calcification of the mats is controlled by seasonal changes in calcium carbonate supersaturation. The structures are the result of periodic in vivo calcification of the surficial layers by low-Mg calcite and early post-mortem calcification of the aggregates below the mat surface by microbially precipitated aragonite. The authors believe this occurrence supports the cyanobacterial origin of stromatoporoids and the more alkaline nature and higher carbonate supersaturation of early Paleozoic seas in which the stromatoporoids lived.]</ABSTRACT>

- 72862 <ABSTRACT>Francoise Peron (1775-1810) and Charles-Alexander Lesueur (1778-1846) sailed with Captain Nicolas Baudin on the great French expedition to Australia from 1800 to 1804. The results of their work were published in 1807 (Peron 1807), translated into English in 1809 and have been very well analyzed recently by Wallace (1984) with the remark: Peron is a figure of equal importance to James Cook. During and after the voyage Peron and Lesueur became pioneers in the study of Medusae. At the beginning of the nineteenth century, the jellyfish were still a puzzle to scientists. Three species placed within the single genus Medusa without specific names but numbered as follows: Medusa 1286, Medusa 1287, Medusa 1288 were placed by Linnaeus (1746) among the Vermes. Medusa was placed among the molluscs by Bruguiere (1791), and with the echinoderms by Cuvier (1817) and Lamarck (1816). In 1799, Cuvier furthered the work of Reaumur (1710) and separated the genus Rhizostomites using the shape and number of mouths as characters. This last character was used by Peron and Lesueur to produce their work and separate the groups of the non-mouthed medusae and many-mouthed medusae. The structure of the mouth was the only character used at that time. The work of Peron and Lesueur was the first to show the diversity of the medusae with a description of 122 species and 29 genera. Their work was first read to the Academy of Sciences in 1808, and a table was published in the Annales du Museum (Peron and Lesueur 1810). It consisted of very specific descriptions which were made from the highly accurate Lesueur drawings. However, neither the drawings, except for the first 14 plates which were of some damaged animals (Lesueur 1815), nor most of the manuscript notes of Peron were ever published. After the death of Peron in 1810, this

immense work did not stand up to critical review by non-specialist scientists. However, in 1980, some 170 years later, the text published in *Annales du Museum d'Histoire naturelle*, Paris (Peron and Lesueur 1809, 1810), the 96 plates painted by Lesueur and the 400-page unpublished manuscript prepared by Peron were finally brought together. Lesueur's plates and Peron's manuscript are deposited in the *Museum d'Histoire naturelle* at Le Havre (France) with the reference numbers 70001 to 70062 and 68325 to 68839. At the outset of the expedition neither Peron nor Lesueur were regarded as zoologists; Peron was enrolled as a medical doctor and Lesueur as an assistant gunner. As the jellyfishes were dominant in the catch in quantity, diversity, coloration and bioluminescence, they became attracted to them.

72927 <ABSTRACT>Ba/Ca, Mg/Ca, Pb/Ca ratios were compared with Sr/Ca ratios
which have been shown to reliably record seasonal-scale temperature
changes in sclerosponges. Sclerosponge aragonite incorporates trace
elements with less vital effects than other organisms. Mg/Ca ratios
show an inverse correlation to temperature. Mg/Ca and Ba/Ca show strong
positive correlation and U/Ca values are 2.5x higher in sclerosponges
than corals and show an insignificant correlation with temperature
dependent Sr/Ca ratios.</ABSTRACT>

72965 <SOURCE>Geology 28, 6: 515-518.</SOURCE>
72966 <ABSTRACT>Lead concentrations have been analyzed on a 223 yr profile through the aragonitic skeleton of the reef-building Caribbean sclerosponge Ceratoporella nicholsoni by using laser- ablation inductively coupled plasma mass-spectroscopy. A parallel study of the 13C distribution in the skeleton validates the previously established mean annual growth rate of 230 µm/yr, at least for long-term important environmental changes. The Pb trend in the specimen displays a general increase from 0.30 ppm ca. A.D.1760 to 2.15 ppm ca. A.D.1984; a major three-fold increase occurred after 1930. This Pb profile is analogous to the results acquired from ice and coral cores and clearly highlights the potential of sclerosponges as a new proxy of environmental changes for time series extending over several centuries.</ABSTRACT>

72979 <ABSTRACT>Sponges (Porifera) belong to the most common and in terms of their biomass dominant sessile aquatic animals. The fact that sponges are important sources of raw material is well known due to the world wide use of Spongia officinalis, the bath sponge (order Dictyoceratida). Its massive organic skeleton of spongin and the absence of spicules makes this sponge suitable as a hygienic article. Bath sponges have been used over centuries for cleaning wounds, for contraception and even as implant after breast cancer operations (Arndt 1938). During Man's history, many different types of medicine, mainly as powders, have been made of dried sponges and used against all kinds of diseases. The oldest pharmaceutical sponge utilisation was the ashes of burned bath sponges, which because of its high iodine content has proven to be an efficacious medicine against diseases of the thyroid gland. 73017 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 227-229.</SOURCE>
73018 <ABSTRACT>Total genomic DNA of the four freshwater sponge species common in Belgium, Ephydatia fluviatilis, Ephydatia muelleri, Spongilia lacustris and Eunapius fragilis was isolated and restricted by the Eco RI endonuclease. Southern blot hybridization with a radiolabelled E. fluviatilis homeobox (Efh-1) revealed hybridization bands in the four species studied. Two restriction fragments of 2.2 kb and 5.4 kb were identified in E. fluviatilis and E. muelleri DNAs whereas in S. lacustris and Eunapius fragilis DNAs, only one fragment of 2.3 kb was detected. Our results demonstrate the existence of homeobox-containing genes in the four species. With Eco RI, no differences were observed between E. fluviatilis and E. muelleri, nor between S. lacustris and E. fragilis. It is suggested that S. lacustris and E. fragilis might be taxonomically related to each other as closely as are E. fluviatilis and E. muelleri. [original abstract]</ABSTRACT>

73029 <TITLE>A revised classification of Spongia mycofijiensis.</TITLE>

- 73030 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 117-122.</SOURCE>
- 73031 <ABSTRACT>The taxonomy of the Indo-Pacific sponge *Spongia mycofijiensis*, order Dictyoceratida, was investigated with particular regard to the appropriate genus assignment. This species, initially collected in Fiji in 1987, was noted for the presence of its unusual secondary metabolite chemistry. Since this time, there has been discussion of two alternative assignments for the species, namely *Leiosella* and *Hyattella*. Type specimens were studied from related genera of the families Spongiidae and Thorectidae, including *Spongia*, *Leiosella*, *Hyattella*, *Coscinoderma*, *Lendenfeldia*, *Hippospongia*, *Dactylospongia* and *Cacospongia*. It was found that the skeleton compared most closely to members of the genus *Cacospongia*, family Thorectidae (= *Irciniidae*) and is therefore concluded that the species be reassigned to this genus. - 73043 <SOURCE>Mar. Ecol. prog. Ser. 145: 77-85.</SOURCE>
- 73044 <ABSTRACT>Dense bush-like clumps of several hundred individuals of a new species of Cladorhiza (Demospongiae, Poecilosclerida) have been observed near methane sources in mud volcanoes, 4718 to 4943m deep in the Barbados Trench. The sponge tissue contains two main morphological types of extracellular symbiotic bacteria: small rodshaped cells and larger coccoid cells with stacked membranes. Stable carbon isotope values, the presence of MeDH and ultrastructural observations all indicate that at least some of the symbionts are methanotrophic. * Ultrastructural evidence of intracellular digestion of the symbionts and the stable C and N values suggest that the sponge obtains a significant portion of its nutrition from the symbionts. Ultrastructure of the sponge embryo suggests direct transmission through generations in brooded embryos. The sponge also maintains a carnivorous feeding habit on tiny swimming prey, as do other cladorhizids.</ABSTRACT>

- 73394 <SOURCE>Proceedings of the 8th International Coral Reef Symposium, vol. 2: 1427-1432.</SOURCE>
- 73395 <ABSTRACT>The different biomineralization processes of the two " living fossils", *Astrosclera willeyana* and " *Acanthochaetetes* " *wellsi* were studied by epifluorescence microscopy, SEM, TEM, and biochemical analyses. The basal skeleton of *A. willeyana* is made of aragonite spherulites. These spherulites are built in the dermal layer in large vesicle cells (LVC) in the early stages. After a releasing event, the spherules fuse together by epitaxial growth. In " *A. wellsii* the basal skeleton is made of high Mg-calcite. It is constructed of bundles of elongated, tangentially oriented crystals. The biomineralization takes place in three different places in the skeleton, the active zones are localized in the uppermost parts of the skeleton. In both cases the mineralization is associated with highly acidic mucus substances, rich in aspartic and glutamic acid which control the biomineralization processes. The understanding of the biomineralization processes in these two cases gives insight into the formation of ancient reef constructors like the stromatoporoids and chaetetids. 73406 <TITLE>Proceedings of the 5th International Sponge Symposium ' Origin & Outlook'.</TITLE>
73407 <SOURCE>Memoirs of the Queensland Museum 44; 720 pp.</SOURCE>
73408 <ABSTRACT>This is to announce the publication of the Proceedings of the 5th International Sponge Symposium, 'Origin & Outlook'.
The theme of the Symposium, 'Origin & Outlook' (held at the Queensland Museum, Brisbane, in June-July 1998), refers to the adage that scientific progress rests on the knowledge of the past, and reflects the productive interaction between palaeontology, biology, chemistry, ecology, cytology, molecular biology and other disciplines as multidisciplinary approaches to the strange but innovative world of sponges. * The Proceedings volume contains 720 pages, comprising 4 invited papers, 67 peer-reviewed general papers, and an additional 72 'Notes' scattered throughout the volume (the latter consisting of other abstracts of papers and posters presented at the Symposium). The Proceedings volume contains information on all aspects of sponge sciences, encompassed a broad range of topics, including: the production of chemicals and the chemical ecology of sponge metabolites with pharmaceutical potential; commercial sponge fisheries and their human impacts; sponge cell behaviour and their immunological implications; the role of sponges as pollution indicators and their ecological interactions with other communities; the role of ' living fossil' sponges in coral reef geomorphology; advances in the origins and relationships of Porifera as evidenced by molecular biology; recent discoveries in biodiversity, evolution, biogeography and palaeontology of the phylum; and the physiology, ultrastructure and interactions of sponges with symbiotic microbes. [book presentation]</ABSTRACT>

- 73771 <SOURCE>Biotechnic and Histochemistry 78, 2-4: 191-199.PMID 14714883</SOURCE>
- 73772 <ABSTRACT>Siliceous and calcareous sponges commonly are treated with acid to remove the spicules prior to embedding and cutting for histological investigations. Histology of spiculated sponge tissue represents a challenging problem in sponge histotechnology. Furthermore, fluorescence in situ hybridization (FISH), a key method for studying sponge-associated microbes, is not possible after acid treatment. For a broad range of siliceous sponge species, we developed and evaluated methods for embedding in paraffin, methylmethacrylate resins, LR white resin and cryomatrix. Different methods for cutting tissue blocks as well as mounting and staining sections also were tested. Our aim was to enable histological investigations and FISH without prior removal of the spicules. To obtain an overview of tissue and skeleton arrangement, we recommend embedding tissue blocks with LR white resin combined with en bloc staining techniques for large specimens with thick and numerous spicules, but paraffin embedding and subsequent staining for whole small specimens. For FISH on siliceous sponges, we recommend Histocryl embedding if the spicule content is high, but paraffin embedding if it is low. Classical histological techniques are used for detailed tissue examinations. [original abstract]</ABSTRACT>

- 73810 <SOURCE>BioEssays 31: 89-97.</SOURCE>
- 73811 <ABSTRACT>Sponges branch basally in the metazoan phylogenetic tree and are believed to be composed of four distinct lineages with still uncertain relationships. Indeed, some molecular studies propose that Homoscleromorpha may be a fourth Sponge lineage, distinct from Demospongiae in which they were traditionally classified. They harbour many features that distinguish them from other sponges and are more evocative of those of the eumetazoans. They are notably the only sponges to possess a basement membrane with collagen IV and specialized cell junctions, thus possessing true epithelia. Among Homoscleromorphs, we have chosen *Oscarella lobularis* as a model species. This common and easily accessible sponge is characterized by relatively simple histology and cell composition, absence of skeleton, and strongly pronounced epithelial structure. In this review, we explore the specific features that make *O. lobularis* a promising homoscleromorph sponge model for evolutionary and developmental researches.</ABSTRACT>

 <ABSTRACT>Petrobiona massiliana is a Recent pharetronid sponge with a secondary basal skeleton composed of high Mg calcite. Petrobiona is linked with the subclass Calcaronea. The basal skeleton is mainly constructed of elongated spherulitic elements. The living tissue of the sponge is restricted to the upper part of the calcareous skeleton, except for narrow canals which penetrate the basal skeleton. The basal skeleton grows within an extremely thin mucus layer between the pinacoderm of the living sponge and the substrate or ontogenetically older basal skeleton. This layer is called the extra-pinacodermal mucus layer. The primary basal skeleton elements are called sclerodermites or elongated cement-chips and grow within the outer-pinacodermal space. The shape of the chips is influenced by the upward movement of sponge tissue during growth. The spicular skeleton of the sponge is partly entrapped by syn-vivo-formed cement-chips. Chemistry of the spicules is nearly similar to the primary elements. An early diagenetic neomorphic process alters the single Mg calcite crystals of the spicules into polycrystalline, granular, or prismatic structures. Within the oldest parts of the basal skeleton the entire structure of the spicules is changed into diagenetic spherulites. Stable isotope content (C13/ O18) of the primary cement-chips and spicules are nearly similar. Cements of the basal skeleton differ only in more positive O18 values, a typical diagenetic feature. Remarkable are relatively high C13 values (+2,3). A strong vital effect (e.g. high content of respirative CO2) is therefore not noticed. The basal skeleton of Petrobiona was compared with another pharetronid species of the Calcaronea group, Minchinella lamellosa. This particular sponge is a true living fossil and is characterized by a rigid interior choanosomal spicular skeleton. This second type of pharetronid basal skeleton is constructed of spicules which are connected by high Mg calcite cements, analogous to with the primary cement-chips of Petrobiona. Chemical data as well as stable isotope content are comparable with Petrobiona. [fragment of extensive original summary]

- 73850 <ABSTRACT>well illustrated (112 drawings and black and white photos) important new contribution to sponge biology. The book represents on ca. 100 pages the results of Prof. Weissenfels and co-workers investigations during the last sixteen years on four European fresh water sponges (Ephydatia fluviatilis (L.), E. muelleri (Lieberkohn), Spongilla lacustris (L.), and Eunapius (Spongilla) fragills (Leidy) and therefore the current knowledge of this group. Weissenfels's group was able to cultivate fresh water sponges in aquaria, the species Ephydatia fluviatilis was the main object of research. Important is, the new developed and used SEM-preparation technique (critical point drying) to demonstrate the outer shape of cells and other soft tissue characters beside well done TEM micrographs. The author gives an extremely good overview on the ontogenetic development of a young sponge hatching from a gemmule or developed from an incubated parenchymella-larvae. All stages of tissue development are figured with

SEM, TEM, and LM micrographs and described in simple but informative German, which allows not native speakers to understand the main content. Beside the characteristics of tissue structures different cell types, and ontogenetic development, physiology aspects are described and help to understand e.g. how a sponge feeds, how an injured sponge recreates, and how organic- and mineralized skeletal elements are constructed. The problem of individuality of a sponge is discussed. An ontogenetic ("phylogenetic") tree of sponge cells is given and allows a short overview on the different sponge cell types and their function. The book is made specially for biologists and students of biology. I believe this book is good also for paleontologists, because it gives an excellent overview on the anatomy, function morphology of certain characters, the physiology of the excretions processes (function of the pore- and channel system), and finally the formation of the collagen/spongine- and spicule skeleton. The latter is very important for paleontologists to understand more about sponge skeletons in respect of taxonomy and phylogeny. Recommendation: necessary for all scientists who are working on sponges and closely related organisms like "stromatoporoids", "chaetetids", "sphinctozoans" and "archeocyathids" and should be available in every scientific library.  73863 <ABSTRACT>Sanidastra yokotonensis Volkmer-Ribeiro and watanabe 1983 was known till now only from the type locality in the eastern Japan. We refer here on three new findings from running waters of Corsica and Sardinia Islands. The diagnostic characters of our specimens, such as spicules morphology and gemmule structure, fit well with those of the original description. The peculiar disjunct distribution is intriguing and we propose some hypotheses to explain it. We discuss also some aspects of the systematic position of this species. [original abstract] </ABSTRACT>

73914 <SOURCE>Bochumer geol. geotechn. Arb. 15: 310.</SOURCE>
73915 <ABSTRACT>The study of the quantitative transformation in the diagenesis of Mg-calcite (especially with regard to the coronas of the sea-urchin Echinocyaas pusillus, to regular echinoid spines, to coralline algae, and to skeletons of the bryozoan Sertella beaniana) requires a detailed knowledge of the used methods (mainly XRD-analysis) and of the composition of modern carbonate material. For this reason the chapters concerning diagenesis are preceded by a methodic summary and an extensive description of the MgCO3-content of modern calcitic skeletons. Examples from the Greek coasts are used to explain the character, environment, and extent of the Mg-calcite diagenesis. Different patterns of diagenesis are used to illustrate the regional importance of diagenetic investigations. Special aspects of Mg-calcite diagenesis, referred to in this study, are dolomitization, Fe-calcitization, cathodoluminescence, silicification, and undulosity of Mg-calcites.</ABSTRACT>

73926 <TITLE>Coral Reefs: Coral's adaptive response to climate change.
</TITLE>
73927 <SOURCE>Nature 430: 741. [brief communication]</SOURCE>
73928 <ABSTRACT>The long-term response of coral reefs to climate change depends on the ability of reef-building coral symbioses to adapt or acclimatize to warmer temperatures, but there has been no direct evidence that such a response can occur. Here we show that corals containing unusual algal symbionts that are thermally tolerant and commonly associated with high-temperature environments are much more abundant on reefs that have been severely affected by recent climate change. This adaptive shift in symbiont communities indicates that these devastated reefs could be more resistant to future thermal stress, resulting in significantly longer extinction times for surviving corals than had been previously assumed. </TITLE>
73940 <SOURCE>Science 301, 5635: 929-933.</SOURCE>
73941 <ABSTRACT>The diversity, frequency, and scale of human impacts on coral reefs are increasing to the extent that reefs are threatened globally. Projected increases in carbon dioxide and temperature over the next 50 years exceed the conditions under which coral reefs have flourished over the past half-million years. However, reefs will change rather than disappear entirely, with some species already showing far greater tolerance to climate change and coral bleaching than others. International integration of management strategies that support reef resilience need to be vigorously implemented, and complemented by strong policy decisions to reduce the rate of global warming. 73952 <TITLE>A new estimate of global reefal carbonate production including the fore-reefs.</TITLE>
73953 <SOURCE>Global and Planetary Change 43: 1-18.</SOURCE>
73954 <ABSTRACT>Reefal carbonate production is an important component of the carbon cycle. In this paper, the methods for assessing this production are compared. Data on framework-dominated and biodetritusdominated for-reefs are integrated for new estimates of the global reef area (304.000 - 345.000km²), of the production in reef-flat to fore-reef transects (average 0,9 - 2,7 kg.m⁻² year⁻¹), and of the

production in the worlds reefs (0,65 – 0,83 Gt year⁻¹). These estimates are the first to incorporate the recently published global reef-flat area and to integrate fore-reef data from all reef provinces. The amount of reefal carbonate production at the local, regional, and even more at the global scale remains poorly constrained of few data.

73966 <SOURCE>Nature 429: 827-833. [Nature review]</SOURCE>

73967 <ABSTRACT>The world-wide decline of coral reefs calls for an urgent reassessment of current management practices. Confronting large-scale crisis requires a major scaling-up of management efforts based on an improved understanding of the ecological processes that underlie reef resilience. Managing for improved resilience, incorporating the role of human activity in shaping ecosystems, provides basis of coping with uncertainty, future changes and ecological surprises. Here we review the ecological roles of critical functional groups (for both corals and reef fishes) that are fundamental to understanding resilience and avoiding phase shifts from coral dominance to less desirable, degraded ecosystems. We identify striking biogeographic differences in the species richness and composition of functional groups which highlight the vulnerability of Caribbean reef ecosystems. These findings have profound implications for restoration of degraded reefs, management of fisheries, and the focus on marine protected areas and biodiversity hotspots as priorities for conservation.</ABSTRACT>

73993 <ABSTRACT>[Not everyone agrees that reefs are shrinking. According to

calculations by Joan Kleypas of the US National Center for Atmosphere Research, increasing CO₂ should already be making reefs grow more slowly. But exactly the opposite may be true on the Great Barrier Reef, according to a study of old coral skeletons by Dave Barnes of the Australian Institute of Marine Science. Calcification rates for the major reef-building genus *Porites*, he found, were 4 per cent higher from 1930 to 1979 than for each of the three preceding 50-year periods, perhaps because rising ocean temperatures gave the corals a growth boost. So what happened to the calcification problem? In follow-up experiments in the laboratory, Barnes found a possible explanation: as CO₂ concentrations rise to levels approaching double the pre-industrial norm, reef rocks release carbonate in a form known as magnesian calcite. This has a buffering effect, shifting the acidity of ocean water back towards its normal value and so stimulating calcification. At about the same time, Robert Halley and his colleagues with the US Geological Survey in St. Petersburg, Florida, used an underwater chamber on an actual reef to monitor chemical responses to raised CO₂ levels. They observe the same buffering phenomenon. "we found it occurred at much less than a doubling of atmospheric CO₂"; he says. Many experts doubt this buffering mechanism will do much to offset the expected decrease in calcification, though. Researchers led by Chris Langdon of Columbia University saw no sign of buffering at doubled CO₂ levels in the Biosphere 2 experiments, for example. Halley counters that this may simple be due to the oversimplified nature of the Biosphere reef. For example, he notes, in natural reefs the surf produces a soluble fine sediment that is absent in Biosphere 2. But even if buffering takes place, mixing by ocean currents will likely overwhelm any locally produced effects on water chemistry, says Kleypas. "I think it might help some reefs in very calm, enclosed areas," she says, "but I don't think it's going to operate on a large scale."

74044 <SOURCE>Geology 23, 1: 4-8.</SOURCE>
74045 <ABSTRACT>Elevations and ages of drowned Acropora palmata reefs from the Caribbean-Atlantic region document three catastrophic, metre-scale sea-level-rise events during the last deglaciation. These catastrophic rises were synchronous with (1) collapse of the Laurentide and Antarctic ice sheets, (2) dramatic reorganization of ocean-atmosphere circulation, and (3) releases of huge volumes of subglacial and proglacial meltwater. This correlation suggests that release of stored meltwater periodically destabilized ice sheets, causing them to collapse and send huge fleets of icebergs into the Atlantic. Massive inputs of ice not only produced catastrophic sea-level rise, drowning reefs and destabilizing other ice sheets, but also rapidly reduced the elevation of the Laurentide ice sheet, flipping atmospheric circulation patterns and forcing warm equatorial waters into the frigid North Atlantic. Such dramatic evidence of catastrophic climate and sea-level change during deglaciation has potentially disastrous implications for the future, especially as the stability of remaining ice sheets - such as in west Antarctica - is in question.</ABSTRACT>

- 74057 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 49-61.</SOURCE>
- 74058 <ABSTRACT>A database for storing information from a survey of the sublittoral benthos of the Northern Ireland coast was developed in the Ulster Museum during the period 1982-1985. The database included a thesaurus of species names compiled with the intention of covering all marine species known in the British Isles. This species dictionary was then edited and published by the Marine Conservation Society, with individual lists being checked by experts in each group. Code numbers allocated to the species were used to store information on the species present at each site surveyed. * These data have now been transferred to a new database, programmed in Advanced Revelation. The relational features of Advanced Revelation have been used to store a hierarchical Linnaean taxonomy, enabling sorting of species in taxonomic order while taking into account changing taxonomies. Special consideration has been given to the coding of synonymous species names. Literature references have been incorporated into the database and linked to the species names. Specimens in the Ulster Museum collections and in the herbarium of University College, Galway have been entered into the database. Field sites have their own tables within the database, and specimen records are linked to the details of the sites where they were collected and the other species recorded at that site. Details of photographs are also stored and linked to species, sites and specimens where appropriate. [...] The Species Directory Marine Database is described and the details of the structure of the database and the validation routines discussed. A strategy for entering all species names for the group Porifera, together with all citations of these names in the literature and all specimens held in museums around the world is presented. - 74070 <SOURCE>Goettinger Arbeiten zur Geologie und Palaontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
- 74071 <ABSTRACT>The effects of different hard substrate surface roughness on the early development of subtidal sessile invertebrate communities were studied over a period of two years in a shallow tidal channel (3m water depth) and a deeper platform edge habitat (27m) near Lee Stocking Island, Exuma Cays, Bahamas. PVC-panels of different surface roughness and panels of natural Key Largo Limestone were deployed and collected after 6, 12 and 24 months of exposure. Sessile invertebrates of nearly all major taxa also found in natural cryptic habitats at each study site recruited on these panels (foraminifera, sponges, hydrozoans, scleractinian corals, bryozoans, synascidian tunicates, serpulid polychaetes and cirriped crustaceans). Recruited communities showed

- clear variations between substrate roughness both in mean number of species per panel and mean diversity with higher values on rough surface PVC. A tendency towards community assimilation between all substrate types from 12 to 24 months of recruitment was observed. Recruitment on smooth surfaces may be a delayed convergence compared to rough surfaces. This is likely to be the consequence of a much slower development of bioorganic films by microbial activities due to low potentials of adhesion on smooth substrates.</ABSTRACT>

74082 <TITLE>Grazing and Bioerosion by Herbivorous Fishes - Key Processes Structuring Coral Reef Communities.</TITLE>
74083 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
74084 <ABSTRACT>Recolonization experiments were carried out in 10 and 20m depths within a fore reef area near Aqaba (Red Sea). Substrates were exposed in different orientations towards light and in different depths. Grazing by Diadema setosum was avoided by the experimental design. The recolonization process of these substrates was heavily affected by grazing herbivorous fish. Experimental substrates, made of coral skeleton were measured before and after exposition. The loss of material quantifies the impact of grazing. The rate of erosion varies with orientation of the substrates and depths. Grazing fish belonged mostly to families unsuspecting of being active bioeroders. Bioerosion rates were compared with net carbonate production in the respective area. A theoretical scenario of the impact of herbivorous fish on coral reef communities is deduced. The study will present how grazing by herbivorous fish is one of the major control factor structuring coral reef communities.</ABSTRACT>

74097 <ABSTRACT>Integrated electrochemical and biogenic deposition of hard material in sea water provides an attractive substrate for many hard bottom settlers. Brucite, aragonite and other minerals are precipitated from the ambient seawater on a cathode of the shape desired. The integration of direct-current phases and dead phases permits the calcareous matter to be deposited by electrochemical precipitation and by the secretion of sessile organisms. The physical substrate is colonized by a highly diverse community of marine organisms as they occur on natural hard substances in the sea. This method is well suited for restoring damaged coral reefs and other habitats which have been degraded by industrial activities or by the exploitation of building

- materials in coastal areas.</ABSTRACT>

- 74110 <ABSTRACT>This interim report deals with investigations on key factors controlling reef growth by zoophysiologicals, ecologists, paleontologists and geologists. The different levels of emphasis are the coral animal and the reef community. The main study area is the Red Sea which reaches over 20° latitude up to the northernmost margin of the global coral reef belt. Supplementary results on microborer ecology are provided from the Bahamas. The desert enclosed Red Sea, not influenced by land runoff and only minimally by anthropogenic (urban and touristic) nutrient inputs, is predestined for a study on the principal influence of light on calcification within bathymetrical and latitudinal gradients. Hence, on the level of the zooxanthellate scleractinian animal phototrophic and heterotrophic energy supply and its bearing on calcification are being measured in different coral species - in particular in Porites sp., one of the most important reef builders. The growth of 15 zooxanthellate scleractinians in the Gulf of Aqaba correlates with the annual light cycle. This correlation is observable down to 40m depth. Other growth promoting factors seem to have less influence on coral extension. [first part of extensive summary]</ABSTRACT>

- 74122 <SOURCE>Journal of Sedimentary Petrology 63, 3: 523-527.</SOURCE>
- 74123 <ABSTRACT>A combination of field and theoretical work is used to study controls on the saturation state of aragonite inside a coral-reef framework. A closed-system ion-speciation model is used to evaluate the effect of organic-matter oxidation on the saturation state of aragonite. The aragonite saturation state initially drops below 1 but becomes oversaturated during sulfate reduction. The C:N ratio of the organic matter affects the degree of oversaturation, with N-poor organic material resulting in a system more corrosive to aragonite. Precipitation of sulfide as FeS strongly affects the aragonite saturation state, and systems with much FeS formation will have a stronger tendency to become oversaturated with respect to aragonite. Both precipitation and dissolution of aragonite are predicted at different stages of the organic reaction pathway if the model system is maintained at aragonite saturation. Field data from a coral-reef framework indicate that the system maintains itself at aragonite saturation, and model-predicted changes in dissolved calcium follow those observed in the interstitial waters of the reef. Aragonite

probably acts as a solid-phase buffer in regulating the pH of interstitial waters. Because interstitial water in the reef has a short residence time, the observed equilibration suggests rapid kinetics.

74188 <ABSTRACT>Das Buch ist sowohl ein Erlebnis- als auch Forschungsbericht aus den Riffen des Roten Meeres und des Indopazifiks. Hier werden jedoch nicht die verwirrende, bunte Vielfalt der Rifforganismen und die oftmals phantastischen Unterwasserlandschaften der Korallenriffe in das Zentrum des Interesses gerückt, sondern das Verhalten der Rifftiere zueinander und in Beziehung zu ihrem Lebensraum. So lesen wir unter anderem von Aggressivität und ihrer innerartlichen und zwischenartlichen Kontrolle bei Korallenfischen, von Kannibalismus und Selbstmord unter Gorgonenhauptern, vom Verhalten der Riffseeigel sowie von sozial kontrollierter Wachstumshemmung und Geschlechtsumwandlung bei Anemonenfischen. </TITLE>
74291 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 040: 235-253.
</SOURCE>
74292 <ABSTRACT>The coral-reef hypothesis of deglacial CO₂ buildup in the atmosphere can account for about one-half of the signal seen in ice cores, assuming additional coral-reef growth releases 2 atmospheric carbon masses (ACM). The carbonate dissolution signal on the deep sea floor suggests titration of only 1 ACM. At least 4 ACM of CO₂ must be made available to satisfy the requirements of p CO₂-increase, growth of biosphere and of sedimentary carbon pool, carbonate dissolution on the sea floor, and saturation of newly introduced meltwater. A drop in ocean fertility is called for to provide the missing CO₂. Such a drop is evident in deep-sea cores from the western equatorial Pacific. CO₂ buildup appears to occur as a step, near 13,500 years B.P. Dissolution on the deep-sea floor begins near 11,000 years B.P. The difference of 2,500 years may describe a mixing lag due to meltwater input (the [Worthington Effect](#)). [original summary]</ABSTRACT>

74304 <SOURCE>Developments in marine geology 5, 17: 532 pp., 157 figs; Elsevier. ISBN 978-0-444-53247-3 ISSN 1572-5480</SOURCE>
74305 <ABSTRACT>This book presents both state-of-the art knowledge from Recent coral reefs (1.8 million to a few centuries old) gained since the eighties, and introduces geologists, oceanographers and environmentalists to sedimentological and paleoecological studies of an ecosystem encompassing some of the world's richest biodiversity. Scleractinian reefs first appeared about 300 million years ago. Today coral reef systems provide some of the most sensitive gauges of environmental change, expressing the complex interplay of chemical, physical, geological and biological factors. The topics covered will include the evolutionary history of reef systems and some of the main reef builders since the Cenozoic, the effects of biological and environmental forces on the zonation of reef systems and the distribution of reef organisms and on reef community dynamics through time, changes in the geometry, anatomy and stratigraphy of reef bodies and systems in relation to changes in sea level and tectonics, the distribution patterns of sedimentary (framework or detrital) facies in relation to those of biological communities, the modes and rates of reef accretion (progradation, aggradation versus backstepping; coral growth versus reef growth), the hydrodynamic forces controlling water circulation through reef structures and their relationship to early diagenetic processes, the major diagenetic processes affecting reef bodies through time (replacement and dissolution, dolomitization, phosphatogenesis), and the record of climate change by both individual coral colonies and reef systems over the Quaternary.</ABSTRACT>

74331 <ABSTRACT>Authorized translation of the German book, "Das lebende Riff", published by Verlag Edition Leipzig, German Democratic Republic and by Landbuch Verlag Hannover, Federal Republic of Germany. The book is an up-to-date scientific review concerning recent hermatypic corals and coral reefs. Content: * history of coral research, * structure, growth and diversity of Scleractinia, * environmental factors, * other reef-builders, * coral reefs - their genesis, types and structure, * ecology of reef organisms, * importance and imperilment of coral reefs, * classification and distribution of recent Scleractinia. * The book is useful for scientists, students and all people who want to know more about the physiological and ecological causal connections, and the reasons of danger and devastating and now killing of coral reefs.</ABSTRACT>

74343 <SOURCE>Journal of theoretical Biology 130, 2: 205-212.</SOURCE>
74344 <ABSTRACT>Equations of several metabolic quotients of symbiotic units

are derived taking a zooxanthellate scleractinian coral as a case study but are useful in any plant-animal symbiotic association. These quotients are: the photosynthetic quotient of the coral (PQnet) and zooxanthellae (PQz), and the respiratory quotient of the coral (RQC).

74355 <TITLE>The species richness-energy hypothesis in a system where historical factors are thought to prevail: coral reefs.</TITLE>

74356 <SOURCE>The American Naturalist 148, 1: 138-159.</SOURCE>

74357 <ABSTRACT>Much of the variance in species richness of terrestrial organisms has been related to levels of available energy (the species richness-energy hypothesis). In contrast, the global patterns of coral diversity have been hypothesized to depend mainly on disturbance and historical factors. In this study, we test several general diversity hypotheses as they relate to hermatypic corals by examining the relationships between coral generic richness at 130 sites worldwide and descriptors of the environment that would be suggested by the hypotheses. The best environmental predictors of diversity are mean annual ocean temperature and an estimate of regional coral biomass, which suggests that available energy limits regional generic richness. In contrast, we found little evidence supporting other ecological hypotheses, including the hypotheses that disturbance or environmental stability is an important control of diversity. We also investigated historical hypotheses proposed to explain coral distributions. We found a relationship between coral richness and up-current island density that is consistent with vicariance models of speciation and theories of coral dispersal. Using multiple regression, 71% of the variation in coral generic richness could be statistically explained using a combination of variables representing both ecological and historical factors. Similar patterns exist for both coral species and reef fishes. [original summary]</ABSTRACT>

74459 <TITLE>what is hermatypic? A redefinition of ecological groups in corals and other organisms.</TITLE>
74460 <SOURCE>Coral Reefs ??, 4: 1-9.</SOURCE>
74461 <ABSTRACT>The term hermatypic, as widely used in the literature of extant and fossil scleractinia, includes, by definition (Wells 1933), the confusing generalization of equating reef-building with containing zooxanthellae. In course of time the use of the term diverged into denoting organisms which are either reef-building (including calcareous Rhodophyta) or those that contain zooxanthellae (including soft Alcyonaria). The equation: reef-building corals harbour zooxanthellae and vice-versa, is invalidated by reviewing the various ecological categories of corals such as: reef-building species without the support of zooxanthellae, zooxanthellae-containing corals which inhabit but do not build reefs, zooxanthellae-containing, non-reef-building corals beyond the bathymetric and latitudinal limits of reefs, and framework-erecting corals in deep waters without zooxanthellae. Former attempts to improve the original definition of hermatypic are shown to

be insufficient to match the ecological diversity of corals. A strict terminological separation of the properties zooxanthellae-containing, reef-building and (more generally) framework-building is provided by the use of the revised, respectively new terms zooxanthellate, hermatypic and constructional (with the respective antonyms azooxanthellate, ahermatypic and nonconstructional). This terminology also applies to non-scleractinians.</ABSTRACT>

74472 <TITLE>Compositional heterogeneity and microstructural diversity of coral skeletons: implications for taxonomy and control on early diagenesis.</TITLE>

74473 <SOURCE>Coral Reefs 22, 2: 109-120.</SOURCE>

74474 <ABSTRACT>Fine-skeletal features of scleractinian skeletons were investigated in living colonies, from ultra-thinsections and SEM preparations. In contrast to what is commonly admitted, the coral fiber is a composite structure differing markedly from a simple aragonite crystal unit. The heterogeneity of coral fiber is shown by the occurrence of a micron-scale zonation resulting from incremental growth during cycles of biomineralization. In addition, high magnification SEM reveals that a calcification center corresponds to a particular structural element clearly differentiated from the surrounding fibers and defined by its own crystal arrangement. The duality of this center / fiber arrangement corresponds to a general architecture of scleractinians, resulting from similar processes of skeletogenesis. An additional fine-scale diversity related to taxonomy is reflected by variations in the geometry and crystallinity of centres and also in the strength and regularity of fiber incremental zonation. These initial differences both within the same colony and between distinct taxa would be emphasized during diagenetic history, leading to differential susceptibility of structural elements to diagenetic processes, and also to specific behavior of distinct taxa in relation to diagenesis.</ABSTRACT>

74486 <SOURCE>Encyclopedia of Geology [Selley R. C., Cooks L. R. M. & Plimer I. R. (eds)]: vol. 2: 321-334.</SOURCE>

74487 <ABSTRACT>This paper is an entry to the Encyclopedia of Geology and gives an overview on the actual knowledge of corals and related organisms. "Cnidarian Organization and Classification", "Geological History", "Coral Structure and Taxonomy", and "Coral Ecology and Palaeoecology" are the topics. In "Geological History"the different groups are discussed, their Precambrian origins and the Phanerozoic diversity, the latter characterized by the main groups Hydrozoa, Scyphozoa and Anthozoa. Organization, distinguishing features, origin and relationships are

- treated in more detail - especially of the three main groups Tabulata, Rugosa and Scleractinia. "Coral structure and taxonomy" deals as well with problems of interpretation. Coral classification, Ecology and Paleoecology are discussed with the Scleractinians first and in comparison with those of the Rugosa and Tabulata. Instructive graphs - for example life cycles, geological ranges of zoantharian corals, relationship between septal insertion, and generalized ecological and palaeoecological ranges of the three main groups - and representative figures impart additional information. A glossary and selected references for further reading complete this very informative representation of "Corals and other Cnidaria".</ABSTRACT>

74602 <TITLE>Clonal growth, algal symbiosis, and reef formation by corals.</TITLE>
74603 <SOURCE>Paleobiology 13, 4: 363-378.</SOURCE>
74604 <ABSTRACT>The occurrence of zooxanthellae in Recent scleractinian corals is strongly correlated with their growth form, corallite size, and degree of morphological integration of corallites. The great majority of zooxanthellate corals are multiseriate with small, highly integrated corallites, whereas most corals lacking zooxanthellae are solitary or uniseriate forms with large, poorly integrated corallites. Beginning in the Jurassic, fossil scleractinian faunas are morphologically similar to Recent faunas dominated by zooxanthellate species, strongly implying that most scleractinians contained zooxanthellae by that time. Evidence for Siluro-Devonian tabulates and Triassic scleractinians is equivocal but still suggests that rugosan corals lacked zooxanthellae. Most populations of Recent zooxanthellate corals contribute to reef formation, but many do not. Similarly, fossil corals interpreted to contain zooxanthellae on morphological grounds did not always form reefs. Recent reef formation depends upon a host of environmental factors that have little to do with the possession of zooxanthellae per se. Coral morphology should be a better predictor of the presence of zooxanthellae in fossil corals than their association with reefs.</ABSTRACT>

74655 <SOURCE>Science 312, 5775: 857-858.</SOURCE>
74656 <ABSTRACT>Symbiosis is the most relevant and enduring biological theme in the history of our planet. Photosymbiosis - whereby photosynthetic microorganisms (symbionts) live inside an animal (host), deriving benefits, sometimes mutual - is found today among calcifying foraminifers and giant clams but is best exemplified in corals, the master builders of reefs. Photosymbiosis fosters diversity and novel adaptations. Recent studies on global change, coral degradation, and the future of coral reefs highlight the relevance of photosymbiosis to reef evolution. 74667 <TITLE>Use of fractal dimensions to quantify coral shape.</TITLE>
74668 <SOURCE>Coral Reefs 26, 3: 541-550.</SOURCE>
74669 <ABSTRACT>A morphometrical method to quantify and characterize coral corallites using Richardson Plots and Kaye's notion of fractal dimensions is presented. A Jurassic coral species (Aplosmilia spinosa) and five Recent coral species were compared using the Box-Counting Method. This method enables the characterization of their morphologies at calicular and septal levels by their fractal dimensions (structural and textural). Moreover, it is possible to determine differences between species of Montastraea and to tackle the high phenotypic plasticity of Montastraea annularis. The use of fractal dimensions versus conventional methods (e.g., measurements of linear dimensions with a calliper, landmarks, Fourier analyses) to explore a rugged boundary object is discussed. It appears that fractal methods have the potential to considerably simplify the morphometrical and statistical approaches, and be a valuable addition to methods based on Euclidean geometry.</ABSTRACT>

74771 <TITLE>Gerolsteiner Fossilien in der Sammlung Goethe.</TITLE>
74772 <SOURCE>Die Eifel 85: 89-90.</SOURCE>
74773 <ABSTRACT>It easily falls into oblivion that the greatest German poet Johann Wolfgang Goethe also had a secondary occupation. As a " Private Legation Councillor" of the dukedom Sachsen-Weimar he - among other things - was endeavoured to revive the mining industry. This led him to deal with geology and mineralogy more thoroughly. He not only started a mineralogical collection in which fossils also existed, he also grappled with geological questions. In 1816 Goethe received three fossils from Gerolstein together with some other pieces. These specimens can be seen in the illustrations 1-3. whereas Calceola sandalina Linne (fig. 1) is obvious, Favosites gotlandica Goldfuss (fig. 2) can only be classed to the genus Favosites Lamarck in a wider sense. It seems doubtful whether the coral fragment referred to as Cyathophyllum helianthoides (fig. 3) belongs to the species of Goldfuss. [fragment of paper]</ABSTRACT>

- 74837 <SOURCE>Mitt. Zool. Mus. Berlin 67,1: 209-218.</SOURCE>
- 74838 <ABSTRACT>Existing coral reef theories fail to explain the origin of all types of coral reefs, because biological aspects are insufficiently considered. However, biological factors, especially metabolism of

symbiotic, hermatypic corals, are among the most important in the construction of coral reefs, despite the importance of geological, palaeoclimatic and hydrographic features. Of the different ways of feeding, the autotrophic one is the most effective for corals living in shallow waters. The intracellular cycling of metabolic products of host and symbiont uses the minimum of energy, leaving more energy available for growth, reproduction and production of calcium carbonate. Adaptation to different environmental factors by corals at different depths leads to the power of the hermatypic corals to compensate for oscillations of sea floor and relative sea level. Therefore, the biologic complex is the central point in understanding the origin of coral reefs. Because of the adaptational peculiarity of corals and their ability to compensate for environmental alterations, this proposal is called the coral reef theory of compensation. The model is valid for all reef types of all coral reef regions.

</TITLE>
74863 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.):
Paleobiology and Biology of Corals]: 81-105.</SOURCE>
74864 <ABSTRACT>within a family, genera are usually separated on the basis of
their colonial structure. The periodic occurrence of transgeneric
highly variable specific units (spectra) in the fossil record poses
nomenclatural and phylogenetic problems. A detailed example among
Jurassic montlivaltiids is presented in this paper involving the genera
Montlivaltia, Coenotheca, Thecosmilia, Latiphyllia and Complexastrea.
These spectra are related to peculiar unstable nonreefal environments
and are characterized by the dominance of young stages of the colonial
growth (astogeny). The arising nomenclatural difficulties are solved by
way of spectral nomenclature which allows naming morphological types,
as well as taxonomic units and keeping some stability within the
general frame of nominal taxa. Genera correspond to grades (solitary,
thamnasterioid, phaceloid, meandroid, cerioid) rather than clades and
the colonial structure is a labile character. Several alternative
phylogenetic hypotheses are proposed, among which, some can renew our
vision of this group and emphasize that the iterative production of
generic level shapes is best explained by mean of heterochronic
processes. It is suggested that testing of these hypotheses be extended
to other families such as Microsolenidae, Stylophyllidae or Fungiidae.

</TITLE>
74876 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.):
Paleobiology and Biology of Corals]: 249-291.</SOURCE>
74877 <ABSTRACT>There is a fundamental ecologic differentiation between
zooxanthellate and non-zooxanthellate corals. This paper reviews
factors which govern the stable carbon and oxygen isotopic composition
of these groups of corals. Although the stable carbon and oxygen
isotope compositions of coral skeletons are strongly influenced by
environmental and physiological factors, the precise mechanisms remain
a matter of debate. In particular the oxygen isotopic composition is
known to be governed by the temperature and the oxygen isotopic
composition of the water and perhaps also by kinetic factors. In
contrast the carbon isotopic composition is controlled by a combination
of photosynthesis, respiration, autotrophy, heterotrophy, and the
isotopic composition of dissolved inorganic carbon. Using a combination
of carbon and oxygen isotopes it is possible to distinguish
zooxanthellate from non-zooxanthellate corals.</ABSTRACT>

74888 <TITLE>Corals as Proxy Recorders of Volcanic Activity: Evidence from
Banda Api, Indonesia.</TITLE>
74889 <SOURCE>Palaios 11, 3: 286-292.</SOURCE>
74890 <ABSTRACT>Corals growing on the flanks of Banda Api, Indonesia, contain
records of volcanic activity which occurred in May, 1988. Ashfall
killed portions of some massive coral colonies (Porties lobata),
resulting in the formation of death surfaces. These surfaces were
preferential sites for extensive bioerosion and incorporation of
volcanic ash into underlying skeletal pores. Subsequent coral
regeneration resulted in the preservation of death / regrowth surfaces
overlying trapped volcanic ash. An orange-colored iron-rich chemical
precipitate is preserved in the skeletons of corals which survived the
volcanic event. These distinct orange bands are contemporaneous with
the death / regrowth surfaces. The iron banding is interpreted as being
a product of hydrothermal activity which accompanied volcanism
X-radiographs of coral skeletons confirm that the timing of formation
of both the death surfaces and the orange banding is coincident with
the 1988 eruption. The features preserved in these corals may be
valuable proxy indicators of volcanic events in analogous recent and
ancient environments.</ABSTRACT>

- 75007 <ABSTRACT>The historical development of research on density banding and related features of cy-clomorphic growth are briefly reviewed. Since the growth of interest in sclerochronology in the early 1970's work on Recent and fossil corals has proceeded quite separately. In Palaeozoic corals, it has been the practice to study and illustrate density banding in acetate peel or thin sections, whilst in Recent corals, X-radiography of thick (± 10 mm) slices has been almost universally the rule. The problems inherent in this latter practice are discussed. A study of the structure of density banding in Recent and fossil corals underlines the close similarity between these features in the two groups and supports their interpretation as comparable in origin and temporal significance.</ABSTRACT>

- 75019 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 185-198. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
- 75020 <ABSTRACT>Symbiosis means living together and encompasses various types of associations between different species, ranging from parasitism through commensalism and amensalism to mutualism. Instances of macrosymbiosis involving modern zoantharian corals are numerous, especially in reefs, but only a small proportion of these are likely to be preserved and recognizable in fossil material. Sessile symbionts have the best potential for fossilization and recognition. Fossil coral macro-symbioses can be classified conveniently into encrusting, boring and intergrowth categories. Trophic relationships between symbionts and the effects of the symbionts on each others fitness are matters of speculation, but data on obligacy, taxonomic specificity, structural integration of symbionts etc. are accessible in fossil material. A preliminary review of coral macrosymbioses suggests that: (a) few symbioses are species specific and obligate for both partners; (b) although some symbionts show apparent adaptations for living in symbiosis, convincing examples of coevolution have yet to be demonstrated; (c) symbioses peaked in numbers during the Devonian, declined in the later Paleozoic, and increased towards modern high levels from about the Miocene onwards; (d) whereas encrusting and

- intergrowth symbioses predominated in the Paleozoic, boring and intergrowth symbioses are commoner at the present day. </ABSTRACT>

- 75033 <ABSTRACT>Species of Caribbean Porites were recognized independently in material collected from St. Croix and Florida using live tissue, allozyme, and morphometric techniques. Preliminary results suggest close correspondence between methods, although more subgroups can be distinguished using live tissues and allozymes. Although no morphometric differences separated three samples of P. "astreoides ", differences in allele frequencies and pigmentation suggest the existence of two species. Morphometric and allele frequency differences both suggest that two species exist within samples of P. "divaricata ". Both approaches also suggest that corals collected as P. "furcata" from St. Croix and as P. "porites" from Miami are the same species; P. "furcata" and P. "porites" from St. Croix can be distinguished by both techniques. Phylogenies constructed separately using the two approaches also tend to agree. Incorporation of fossils into the analysis suggests that two radiations may have occurred in the Caribbean since the Eocene: (1) early to middle Miocene and (2) Pleistocene to early Holocene. Extinctions appear concentrated between the late Pliocene and early Holocene.</ABSTRACT>

75070 <TITLE>Fundamental factors, material properties and incipient diagenesis: a caveat case study of scleractinian analogues for rugosan interpretation.</TITLE>
75071 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 117-127.</SOURCE>
75072 <ABSTRACT>This paper is concerned with the hypothesis that in overlooking the information which can be derived from living corals we are in danger of ignoring data which is critical to the proper interpretation of the highly sensitive chemical signals currently being derived from them. This has implications for the interpretation of both extant and extinct groups. The fundamental feature which distinguishes this paper from the many more sophisticated studies of living scleractinians and their more recent geological records in the Pleistocene concerns the nature of the material properties involved. It draws attention to the influential role of the critical sizes of the individual components in relation to their preparation and resultant geologic implications. The main diagenetic contrasts in preservation appear to relate to the precise timing of the sealing-off of the coralla from the surrounding migratory fluids. Where an influx of clay mineral laden waters follows immediately after a toxic event the likelihood of the preservation of calical details is higher than normal. Thus clay rich horizons are likely to contain the best preserved external features although subsequent penetration of the seal may result in the complete replacement of the internal fabric.</ABSTRACT>

75084 <SOURCE>Geol. Palaeont. Mitt. Innsbruck 22: 43-59.</SOURCE>
75085 <ABSTRACT>The fossil records of rugose corals are rare of swallowed bodies enclosed in the intratabular and intradissepimental spaces. In the most well known examples of bodies enclosed in the fossil skeletons they are probably swallowed through the gastrovascular cavity of the polyp and then they were atrophied together with parts of the basal soft body. These particles became an enclosed part of the extracorporeal skeleton. Presupposing that living beings can be understood as organismic constructions different functions performing the hydraulic, machine-like, and energy conducting entities can be explained. By analyzing anthozoan polyps some very important and indispensable functions are realized. Retention of the hydraulic filling by a valve like effect of the mouth tube, the ingestion of large food particles and the ejection of swallowed objects through the mouth tube are possible. Particles which get into the spaces between the tethering mesenteries could not be ejected on the usual way back through the pharynx. Getting rid of such swallowed particles is only

possible by atrophying the basal soft body where the swallowed body has been deposited. Thereby the particle is enclosed in the extracorporeal skeleton.</ABSTRACT>

75096 <TITLE>Effect of calcium carbonate saturation of seawater on coral calcification.</TITLE>
75097 <SOURCE>Global and Planetary Change 18: 37-46.</SOURCE>
75098 <ABSTRACT>The carbonate chemistry of seawater is usually not considered to be an important factor influencing calcium-carbonate-precipitation by corals because surface seawater is supersaturated with respect to aragonite. Recent reports, however, suggest that it could play a major role in the evolution and biogeography of recent corals. We investigated the calcification rates of five colonies of the zooxanthellate coral *Stylophora pistillata* in synthetic seawater using the alkalinity anomaly technique. Changes in aragonite saturation from 98% to 585% were obtained by manipulating the calcium concentration. The results show a nonlinear increase in calcification rate as a function of aragonite saturation level. Calcification increases nearly 3-fold when aragonite saturation increases from 98% to 390%, i.e., close to the typical present saturation state of tropical seawater. There is no further increase of calcification at saturation values above this threshold. Preliminary data suggest that another corals species, *Acropora* sp., displays a similar behavior. These experimental results suggest: (1) that the rate of calcification does not change significantly within the range of saturation levels corresponding to the last glacial-interglacial cycle, and (2) that it may decrease significantly in the future as a result of the decrease in the saturation level due to anthropogenic release of CO₂ into the atmosphere. Experimental studies that control environmental conditions and seawater composition provide unique opportunities to unravel the response of corals to global environmental changes.</ABSTRACT>

75122 <TITLE>The importance of crises for coral evolution.</TITLE>
75123 <SOURCE>Zhurnal obshchey biologii 56, 2: 200-209.</SOURCE>
75124 <ABSTRACT>In the evolution of corals the epochs of flourishing alternated with crisis. During the crisis and the beginning of the flourishing the evolution rates were maximal. At the time the taxa of highest ranks emerged (families, suborders, orders). Subsequently the evolution rates decreased and were minimal at the end of the epochs of flourishing. 8 crises were established in coral evolution: Postordovic, Postludlov, Serpukhovo-Bashkirian, Lower-Triassic, Lower-Jurassic, Middle-Cretaceous, and Palaeocene. They differ in their significance and duration. The largest and longest of them was the Lower-Triassic crisis. During it the most fundamental taxonomic changes occurred. In the end of Palaeozoic the last clear representatives of Tabulata and Rugosa disappeared, whereas 20 new genera, 10 families, and 6 suborders of the Scleractinia order emerged in the beginning of Middle Triassic. Small Permian solitary rugosae of the family Plerophyllidae were the ancestors of Mesozoic scleractinians. The second largest crisis was Famenian. By the beginning of it the order Heliolitida disappeared, as well as some 30 families and 210 genera of other corals. By the beginning of Carbonic 200 new genera, 20 families, and three suborders of corals emerged. The third largest crisis took place in Lower Jurassic. By the beginning of it approximately 96% of Upper Triassic corals have disappeared, whereas 220 new genera, 22 families, and 3 to 5 new suborders emerged in the end of Lower and in the Middle Jurassic. The epochs flourishing of and crises of coral evolution were not dependent upon the degree of their endemism.</ABSTRACT>

75254 <ABSTRACT>Les auteurs consacrent la première partie de leur exposé à rappeler quelles sont les caractéristiques essentielles, biotiques et abiotiques, des milieux récifaux coralliens: nature des organismes

constructeurs, morphologie des récifs, classification des milieux coralliens, distribution et conditions d'existence des récifs à Madréporaires, tant fossiles qu'actuels. La seconde partie est consacrée à l'examen de la composition, de la répartition et de l'importance des peuplements malacologiques dans ces milieux, en envisageant successivement les Mollusques commensaux ou parasites des Madréporaires hermatypiques, les Mollusques du récif proprement dit, les Mollusques des substrats meubles biogènes, les Mollusques des eaux récifales et périrécifales.

75304 <TITLE>Coloniality in Zoantharian Corals.</TITLE>
75305 <SOURCE>In Boardman, Cheetham and Oliver (eds): Animal Colonies; Dowden, Hutchinson & Ross Inc., Stroudsburg, Pa: 3-27.</SOURCE>
75306 <ABSTRACT>Genera of colonial zoantharian corals have been more numerous than solitary genera through most of Phanerozoic time even though colonial genera were a minority of the Rugosa. Various forms of coralla represent widely different levels of development in terms of both integration within colonies and adaptive success, but the two are not necessarily correlated. Phaceloid rugosans represent a low level of integration with no connection between individuals other than skeletal; in contrast, coenosteoid scleractinians represent a high level of integration with confluent gastro-vascular cavities and coordinated skeleton building. But both forms were very successful in terms of generic diversity and longevity, whereas Paleozoic coenosteoid heliolitoidids were relatively unsuccessful. The evolution of coloniality in zoantharian corals was paralleled by the evolution of the coral-reef building habit. Paleozoic corals built only small reefs, apparently because of slow growth, relative instability, and failure to solve the problem of the disposal of metabolic waste. Mesozoic to Recent corals developed porous skeletons that are strong, stable, and rapidly built. In addition, they have developed an algal symbiosis that has solved the waste problem and increased the rate of CaCO₃ deposition. These factors together have made possible the surf-resistant oceanic reefs of late Mesozoic to Recent time.</ABSTRACT>

75317 <TITLE>Some aspects of colony development in Corals.</TITLE>
75318 <SOURCE>Journal of Paleontology 42, 5: 16-34.</SOURCE>
75319 <ABSTRACT>Many peculiarities of growth and development in colonial metazoans are related to the fact that a true colony is a clone, composed of genetically identical individuals reproduced asexually from a single founding individual. In fossil colonies the close relationship of individuals may be difficult to prove, but it must be assumed for analysis to be meaningful. Intercolony variation is due to the interaction of genetic and environmental controls as in solitary organisms. Intracolony variation may be very limited because of the lack of genetic variation, but microenvironmental differences (situation within colony) may cause enough individual variation to mask the restrictive effect of genetic similarity. Study of the number of major septa in some Devonian solitary and colonial rugose corals shows significantly less variation within colonies than within " populations" or species of colonial, or solitary forms. Greater variation within some colonies may result from either genetic or mechanical accidents. Septal number and diameter are closely correlated in populations and species, but analyses of individuals within colonies frequently show weak or no correlation. Available data suggest: (1) that septal-number variation may be genetically limited in rugose corals and (2) that the general assumption that number of septa is a function of diameter may be in error.</ABSTRACT>

75343 <TITLE>Biology and Geology of Coral Reefs.</TITLE>
75344 <SOURCE>Academic Press, New York and London; vol. 1: Geology 1.; 410 pp.
</SOURCE>
75345 <ABSTRACT>This first geology volume is restricted to chapters dealing with the reefs of particular areas; discussion of topics applicable to coral reefs throughout the world is deferred to the second geology volume. Important additions of our knowledge of corals reefs, particularly the spectacular results that stemmed in recent years from work in the Marshall Islands - seismic surveys and dredging at depths of 1460-3660m, as well as deep borings - are discussed. This work not only provided proof of Darwin's explanation of the origin of deep ocean atolls by progressive subsidence of their foundations but also yielded important conclusions on other aspects of the history of those reefs. Ladd summarizes this work in his chapter on Bikini and Eniwetok Atolls. * Ironically, the stimulus to the undertaking of these studies was the desirability of surveys prior and subsequent to the testing of nuclear explosive devices. The surveys were primarily to document the effects of the explosions, but incidentally, during a few years of study, they yielded far more definitive information on coral atolls than had the total of all previous work. * Similar considerations prompted surveys of Mururoa Atoll in the Tuamotu Archipelago, surveys which in turn produced much new data on the reefs, only some of which can be correlated with data on the atolls of the Marshall Islands. The reefs of French Polynesia, including Mururoa Atoll, as well as those of New Caledonia are described by Chevalier in Chapters 4 and 5. * As Stoddart (Biol. Rev. 44, p. 437) has pointed out and as is briefly discussed by Whitehouse in Chapter 6, Darwin's theory is not necessarily applicable to barrier reefs on continental shelves or surrounding high (continental) islands. Barrier reefs in particular need further study in regard to the nature and geological history of their foundations quite apart from work in other geological fields. * Proposals to establish an air base on one of the islands in the Indian Ocean initiated studies of the fauna of the islands involved, studies which were widened to include most of the reefs in the ocean. The more important features of these reefs are summarized by Stoddart in Chapter 2. [first part of extensive summary] </ABSTRACT>

75369 <TITLE>Flume studies on the stability of model corals as an aid to quantitative palaeoecology.</TITLE>
75370 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 015: 1-27.</SOURCE>
75371 <ABSTRACT>Flume experiments were performed in order to investigate the movement, susceptibility to transport, and final orientation of model corals on various sediments under differing current conditions. Seven sets of models (giving a total of 50 models in all) were studied, first on a fixed bed of coarse sand (representing lithified conditions), then on a free bed of the same material (representing unlithified conditions). All movements of the models and their final orientations were recorded. The experiments began with a study of the relationship between a series of spherical caps (hemispheres) and right-spherical cones, and their competent velocities on a fixed bed. These results were then compared with a second series of models having an effective density believed to be analogous with that of Favosites gothlandicus (Lamarck), a species common in the Wenlock Limestone Formation, and found both in and out of its life position. * From these experiments, conclusions regarding the relative stability and susceptibility to transport of various growth forms were drawn. From the experimental evidence, spherical caps would generally be expected to return to their growth orientation, even after transportation, whereas it is unlikely that the conical forms would regain their growth orientation. These results and conclusions were extended by a study of composite models which indicated the manner in which coral colonies would move when subjected to transportation by an unidirectional current. These models demonstrated how the most stable orientation of these models was size-dependent. * The second group of experiments was carried out on an unlithified bed. Here, interference of the models with the current could be studied and also the resulting effect on the sediment. Scour hollows were developed owing to the intense vorticity generated around the higher models. This removal of sediment results in the undercutting of the model. Two possible situations could then arise. Firstly, the model was removed from the bed, this subsequently resulting in the removal of the previously produced sedimentary structures. Secondly, the models tipped forward into the upcurrent scour hollow and were buried, the associated sedimentary structures undergoing modification. * The relative hydrodynamic theory is included where this helps to clarify the results of the experiments. Finally, the relevance of the experiments to the colonial organisms of the wenlock bioherms is discussed.</ABSTRACT>

75382 <TITLE>Control and distribution of uranium in coral reefs during diagenesis.</TITLE>
75383 <SOURCE>Journal of Sedimentary Petrology 43, 4: 985-997.</SOURCE>
75384 <ABSTRACT>The concentration of about 2ppm of uranium in the aragonitic skeletons of modern scleractinian corals which we studied is a constant value, regardless of occurrence, anatomy or taxonomy. * The presence of cement of aragonite or high magnesian calcite usually raises the concentration of bulk samples to about 3ppm. Modern corals may contain up to 50% of cementing minerals. Organisms, such as corals and coralline algae, while secreting their skeleton, discriminate against the uptake of uranium, whereas the uptake of uranium by mineral cements is less restrained. Aragonite cement contains about 3,6ppm and high-magnesian calcite cement 2,6ppm uranium. * During leaching by fresh water, the aragonite of the skeletons of corals dissolves out. This creates hollow molds which fill with drusy low-magnesian calcite. In emergent reefs from the shores of the Red Sea which display the effects of progressive diagenesis this calcite is enriched in uranium (3,9ppm) beyond that found in marine cements. Second-generation calcite which fills original voids in the coral from the emergent reefs contains a lower level of uranium concentration (1,3ppm). The level of concentration of uranium in low-magnesian calcite of diagenetically altered corals is a function of the availability of uranium in meteoric waters. * In aragonite as well as in high- and low-magnesian calcite uranium replaces calcium or occupies lattice vacancies in the crystal lattice.</ABSTRACT>

75408 <TITLE>Carbon flux through a coral-reef ecosystem: a conceptual model.
</TITLE>
75409 <SOURCE>Journal of Geology 82, 2: 161-171.</SOURCE>
75410 <ABSTRACT>The potential application of modeling techniques to
sedimentological studies of modern carbonate environments is
demonstrated by a suggested conceptual model of the carbon system in a
coral reef ecosystem. A graphic model employed to delineate the
locations and characteristics of carbon flow patterns in the reef
ecosystem modeling is thought to be a valid tool of geological research
which should be considered a necessary first step in studies of systems
such as the one described. The given model is intended to stimulate
discussion about the usefulness of modeling in geological
investigations of coral reefs, particularly in identifying the
geological priorities in coral-reef research. This model will also form
the basis for future simulation analyses.</ABSTRACT>

75603 <TITLE>The role of metabolic nitrogen in Coral calcification.</TITLE>
75604 <SOURCE>Marine Biology 28: 525-552.</SOURCE>
75605 <ABSTRACT>when pieces of the staghorn coral Acropora acuminata are
incubated with 14C-urea, the label is incorporated into skeletal
carbonate. Incorporation of this label differs from that of H14CO3,
suggesting urea is not immediately hydrolysed to provide a further
source of HCO3. The effects of certain organic substrates upon
calcification suggest the ornithine cycle is involved. Citruline, an

ornithine cycle intermediate, is found in high concentrations in the tissues of hermatypic corals. Urea, allantoin, NH₃ and arginine are also present. These compounds are barely detectable in zooxanthella or an ahermatypic coral. The allantoin may be present as calcium salts. It is suggested that allantoin is the medium by which Ca²⁺ and CO₂ are transported to sites of calcification. Hydrolysis of urea, formed by breakdown of allantoin, yields CO₂ and NH₃. The NH₃ may neutralise protons formed during precipitation of CaCO₃ and bring about their removal from sites of calcification. As well as providing urea, the ornithine cycle may also be involved in the removal of NH₃ from sites of calcification.

75759 <TITLE>Septodaeum siluricum, a representative of a new subclass Septodaearia of the Anthozoa, with partial preservation of the soft parts.</TITLE>
75760 <SOURCE>Senckenbergiana lethaea 59, 4/6: 229-273.</SOURCE>
75761 <ABSTRACT>Based on more than 6800 phosphatized, originally organic thecae and 12 specimens with partially preserved soft parts, Septodaeum

siluricum n.g., n.sp., a colony building form ranging from early Ordovician through early Devonian is described. * The phosphatized soft parts consist of a circular stomodaeum, evenly subdivided by commonly 6 radial stomodaeal mesenteries with strong retractor muscles on either side that also operate a stomodaeal membrane spanning the intermesenterial spaces. The peripheral zone is evenly subdivided by 3, 6, 7, or 8 radial complete mesenteries with strong retractor muscles equally well developed on both faces. Orally located intermesenterial spaces are separated from the gastro-vascular cavity by an intermesenterial membrane that represents an aboral-lateral extension of the stomodaeal wall and is operated by retractor muscles of the complete mesenteries. Intercommunication between intermesenterial spaces and gastrovascular cavity is provided by fenestrae. The incomplete mesenteries are short and may reach a total number of 32. The complete mesenteries are inserted singly. Asexual reproduction is by means of lateral increase and mesenterial budding. * Presence of stomodaeum in combination with the mode of asexual reproduction characterizes the new taxon as a representative of the Anthozoa. * The unusual anatomical configuration of the complete mesenteries, the mode of their insertion, as well as the possession of stomodaeal mesenteries, and stomodaeal and intermesenterial membranes, unknown from other Anthozoa, necessitate the placing of Septodaeum siluricum in a new subclass Septodaearia, regarded as an ancient, separate phyletic line of the Anthozoa. 75955 <SOURCE>Nauka, Moskva; 157 pp., 35 figs, 6 tabs.</SOURCE>
75956 <ABSTRACT>A systematic structural analysis of the morphology in

tabulatormorphous corals is presented. Main topics are: the classification of morphological characteristics, their correlated relationship, the correlation between tabulatormorphous coral features, homeomorphic lines in the tabulatormorphous coral system, coral morphology and its relation to reef facies, e.g. problems in the study of the reef's ecosystem, life-forms in corals, the system and the terminology of the life-forms, the contemporary reefs and their paleogeography, morphology and facies, the notion of reef; and the Paleozoic coral life-forms of Eastern Asia.

76006 <TITLE>Morphological limits to diversification of the rugose and tabulate corals.</TITLE>
76007 <SOURCE>Palaeoworld 19, 3-4: 389-400.</SOURCE>
76008 <ABSTRACT>At the family level, the evolution in the compound rugose corals is usually characterized by the progressive integration of corallites. This type of evolution corresponds to paedomorphic processes in the astogeny of colonies: the separation of the daughter polyp from the parent being progressively delayed as compared to the development of the other characters. At the end of the lineage, relations between mature polyps are similar to those existing in the first stages of the increase in the ancestor. * Tabulate corals are strictly colonial and usually have connections between polyp cavities. They can develop colonies similar to those known in the compound rugose corals (fasciculate or massive), but also other forms (such as cateniform, ramose and coenenchymal). However, a relative separation of growth habit exists between rugose and tabulate corals from their radiation during the Ordovician. Besides the differences in colony shapes, corallite diameters are generally larger in the Rugosa than in Tabulata. * Several crises affected Palaeozoic corals, and some of them caused the disappearance of major morphotypes. After these crises, neither the surviving tabulate nor the rugose corals gave rise to new taxa with these forms. The evolutionary processes in post-crisis coral recovery correspond mainly to heterochronic processes. These proceed within the limits of ontogenetic (or astogenetic) variability and do not allow innovations such as a type of colonial development that is not a usual type of increase within a taxon. Therefore, the replacement of extinct habits by an evolutionary convergence of taxa with other major habits does not occur in Palaeozoic corals. These evolutionary processes probably differ from those acting during an original evolutionary radiation. [original abstract]</ABSTRACT>

76073 <ABSTRACT>Der Sektionsname "Paläozoologie I" mit dem Forschungsschwerpunkt "Fossile Nesseltiere" innerhalb der Geologischen Abteilung des Senckenberg-Instituts geht auf die in den

späten sechziger Jahren dieses [XX] Jahrhunderts durchgeführte Neuabgrenzung der Kompetenzen für die verschiedenen Forschungssammlungen zurück; praktisch existiert sie seit dem Arbeitsbeginn des Autors als DFG-Assistent in der Geologischen Abteilung im August 1959 bei Dr. Wolfgang Struve, der als Projektleiter verantwortlich zeichnete. Der [Setzling](#); zu dieser Forschungsrichtung geht aber auf Rudolf Richter zurück: Durch den Erwerb der Sammlung Wedekind im Jahre 1953, durch die Ausbeute der Eifeler Richtschnitte und die von seinen Schülern durchgeführten Neukartierungen der Eifeler Kalkmulden bereitete Rudolf Richter den Boden für das Wachstum dieser damals neuen senckenbergischen Pflanze vor. Nach nur vierzigjährigem Gedeihen ist ihr weiteres Schicksal ungewiß, denn im Frühjahr 1994 nahm der Verfasser seinen Abschied, und es wird keinen Korallenspezialisten mehr in der Sektion geben.

76097 <TITLE>Geometric morphometry: an example using Lophophyllidium proliferum.</TITLE>

76098 <SOURCE>FC&P 27, 1: 33-41.</SOURCE>

76099 <ABSTRACT>The results presented by the analysis of the thin-plate splines has suggested that L. proliferum appears to have had a development centered mainly in two areas, (1) the counter quadrants and (2) its columella. After an initial moment, with enlargement of the corallite following symmetrical growth rates (as suggested by w4 during early juvenile phase), subsequent stages contributed little energy to the development of the remaining regions of the corallite as a whole. That pattern explains clearly the bilateral symmetry of this specimen and when it was acquired. * Since most of the corals of L. proliferum type present a very similar pattern, the model of growth suggested here brings attention to two points, (1) the columella in lophophyllid

corals seems to be a character of taxonomic value and worth further study, and (2) the counter acceleration, very often cited for these corals, seems to be closely related to the form of the columella. A survey of that acceleration among lophophyllids, in time and space, could possibly bring some new data to explain the great variability of the columellar structure in this lineage of simple solitary rugose corals. [conclusions of the paper]

76110 <TITLE>History of the International Association for the Study of Fossil Cnidaria and Porifera.</TITLE>
76111 <SOURCE>FC&P 29, 1: 15.</SOURCE>
76112 <ABSTRACT>Corals and sponges belong to the most important group of fossils - and of living animals as well - giving essential answers to lots of questions in paleontology, and especially geology, for example sedimentology. Constructing reefs - megalopoli of species - coral research played an important role in expanded geological mapping and exploration programs within the last fifty years. Especially in the former Soviet Union and in the USA fossil coral specialists "became numerous enough to warrant formal and informal meetings for communication of current research. In the USSR, formal All-Union Symposia On Fossil Corals were organized on a four-year basis by Academician Boris S. Sokolov beginning in 1963 at Novosibirsk. In the USA, William A. Oliver Jr., organized topical sessions on corals for the Paleontological Society in 1965, leading to annual and other meetings of the Friends of the Corals, an informal group of North American specialists"; (Sando 1997). * To promote the transparency of coral research and its scientific results as well as to open the possibility for an international exchange of ideas and reprints first steps have been done to establish an International Association for the Study of Fossil Cnidaria. At that time the Eastern colleagues were under severe restrictions on travel outside the USSR and the Eastern-block. Therefore, and as proposed at the Second All-Union Symposium at Tallin in 1967, Sokolov started the organization of an International Symposium to include specialists from outside the " Eastern-block"; e.g. the communist sphere. Then, the Third All-Union Symposium in 1971 in Novosibirsk became at the same time the First International Symposium on Fossil Corals (And Some Other Coelenterata). * Until 1999 seven symposia have been held.</ABSTRACT>

76123 <TITLE>Changes of carbonate coral skeletons in deep burial and slight metamorphic conditions: eastern part of the Variscan Orogen in Europe.</TITLE>
76124 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 173-186.</SOURCE>

- 76125 <ABSTRACT>Disconnected Devonian carbonate formations border many nappes and wedge units on the exterior of the Late Carboniferous Variscan Orogen of central Europe. Metamorphic gradient decreases sharply outwards, with disruptions by some nappes. Alterations of the Devonian carbonates range from amphibolite green schist facies to slight burial diagenesis, from inner to outer belts of nappes, respectively. The evolution of carbonate crystal fabrics (including ghosts and relic structures) correlates with thermal alteration of organic matter, illite crystallinity, the conodont alteration index and a leveling off of stable isotope amounts. Bioclasts, mainly the fragments of walls of tabulate corals (genera *Thamnopora*, *Remesia*, *Alveolites*, *Scoliopora* and *Favosites*), were studied to determine their response to the maximum paleotemperature, lithostatic pressure and oriented strain forming the host rocks. Resistance of these fragments to alteration is almost as high as that of low Mg calcite brachiopods or crinoid ossicles that have been rapidly depleted in magnesium. Specific conditions, such as the composition of sediment or early diagenesis of corals produce largely interwoven paths of alteration, but regular changes can be understood through analysis of large quantities of material. Eight typical crystal fabric patterns, here introduced, provide standardized indicators of differing maximum burial conditions. [original abstract] </ABSTRACT>

- 76137 <SOURCE>Bulletin of the Far Eastern Branch, Russian Academy of Sciences 1: 89-104; Vladivostok.</SOURCE>
- 76138 <ABSTRACT>A review of experimental and literature data is devoted to coral evolution and ecology. Anthozoa are known from Vendian deposits (up to 700 million years ago) to recent time. They adapted to depths from intertidal zone to abyssal area and populated regions from tropical to polar zones. Coral fauna and flora form different types of biorelief: bioherms, biostromes, reef massives. Their metabolites are drawn into natural biogeochemical processes. It is shown that solitary and colonial polyps have parallel evolution and their geological history is subdivided into several important stages fixed by the paleontological chronicle. - 76151 <ABSTRACT>This study attempts a revision of the Rugosa at ordinal level using phylogenetic systematics. Three major aims were (1) to test their monophyletic nature, (2) to define at which hierarchical taxonomic level the characters commonly used in rugose systematics were informative and (3) to formulate a hypothesis to demonstrate the

position of the Rugosa in the tree of life. * To accomplish these goals a revision of the Orders Cystiphyllida and Stauriida sensu Hill (1981) was performed. The phylogenetic analysis was undertaken using the two orders of the Rugosa as ingroup, and a combination of fossil corals and extant Anthozoa as outgroup. A total of 126 characters were compiled of which 90 related to biomineralised features and 36 related to soft tissues. Two phylogenetic analyses were performed. The first analysis used Alcyonaria as the prime outgroup yielding 6 trees that were merged into a single tree after optimisation. The second analysis used Tabulacorus, a Cambrian fossil coral, and yielded six trees. These trees were combined into a single tree after optimisation being that tree accepted as the most informative for the problem at hand. The Rugosa appeared as a monophyletic group but eight of the sixteen sub-orders of the Stauriida were dismissed. The Rugosa is the adelphotaxon of a group formed by fossil corals and the Scleractinia with cyclic septal insertion. The major implications for the Anthozoa were (1) the subclass Zoantharia was dismissed and replaced by the subclass Hexacorallia, (2) the subclass Alcyonaria was dismissed and has now the status of a family within the Hexacorallia and (3) the time of origin of the Anthozoa is accepted as Early Cambrian. A new classification for the Anthozoa is provided. [full text of a short paleontological note; possibly description of a finished research project, concerning systematics of the Anthozoa]

76163 <SOURCE>Paläontologische Zeitschrift 67, 3-4: 397-405.</SOURCE>
76164 <ABSTRACT>The database systems PaleoTax and Goniat provide detailed information on literature, taxonomy, morphology and occurrence of fossil invertebrate groups. PaleoTax is designed for Mesozoic corals, Goniat for Paleozoic ammonoids, but both can be modified to cover other fossil groups. Both systems use dBASE format, but with different database structures. PaleoTax aims at the complete storage of all available objective data, Goniat provides determinations based upon morphologic criteria, and includes information on geographic distribution and stratigraphic range of every taxon. A combination of both systems could lead to the establishment of a comprehensive paleontological information system useful for research and practical stratigraphic applications.</ABSTRACT>

76188 <TITLE>Biochemical features of intraskeletal organic matrices within sponge and coral aragonite: implications for diagenetic pathways.</TITLE>
76189 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 164-172.</SOURCE>
76190 <ABSTRACT>Amino acid compositions of organic matrices associated with modern demosponge (Astrosclera and Ceratoporella) and coral (Solenastrea and Porites) skeletons have been studied in different growth zones. Zones investigated in extant coralla range in age from newly mineralized areas in the uppermost parts to 3 or 4 hundred year old areas in their deeper parts. Starting from distinct primary amino acid compositions in living parts of sponge and coral skeletons, biochemical transformations visibly affect organic matrices, especially with regard to variation in aspartic acid concentrations. The influence of extracted organic matrices on in vitro rates of CaCO₃ precipitation was tested experimentally. Both sponge and coral matrices proved to inhibit mineral formation, with a strength that is closely correlated with their amino acid compositions. During diagenesis there is first an increase in aspartic acid concentration, correlated with a marked efficiency of matrix to inhibit CaCO₃ precipitation over 100 years at the most, and second, a reverse tendency, leading to progressive loss of both acidic amino acids and inhibitory strength. Timing of this double stepped diagenetic pattern differs between sponges and corals, and also varies among different species within each group according to their initial biochemical features. - 76333 <ABSTRACT>The arguments advanced previously to include the Archaeocyatha within the Phylum Porifera employed superficial morphological similarities which do not correspond to the present state of knowledge. Two major errors are frequently found in previous studies : 1) the emphasis on the presence or absence of spicules as a definitive argument, and 2) the direct comparison of fossilized skeletal structures with living, soft tissue. Although the skeletal microstructure of the Archaeocyatha is constant and does not correspond to any known type of microstructure in calcified sponges, there is such a great variety of microstructural types within calcified sponges that it is conceivable to consider archaeocyathan microstructure as one of their primitive forms. Recently some microgranules were discovered in one species of verticillites. Direct comparison between verticillites convexus (Sponge) and Korovinella sajanica (Archaeocyatha) attests a great similarity of skeletal morphology, microstructure, and morphogenesis.</ABSTRACT>

76372 <ABSTRACT>Discoveries of living sponges with a calcareous skeleton have led to reevaluation of the affinities of many fossil groups. Archaeocyatha have close similarities with sphinctozoan sponges. Exopore modifications of some sphinctozoans have analogues in the wall pores of certain Archaeocyatha. Some gross morphological comparisons between selected taxa of sphinctozoans and archaeocyaths show striking similarities. Recent discoveries in the Cambrian of Australia suggest a possible pathway for the derivation of sphinctozoans from monocyathine archaeocyaths via modification of pelta and skeletal microstructure.</ABSTRACT>

76436 <SOURCE>Palaios 7: 131-156.</SOURCE>
76437 <ABSTRACT>A modular organization confers many ecological advantages in reef-building settings, such as indeterminate growth leading to larger size, greater powers of regeneration, and an ability to encrust and gain secure attachment to substrates. The Archaeocyatha, an early Cambrian group of calcified sponges, were the first skeletal metazoans to develop a modular habit and to be associated with reefs. Archaeocyaths show the predicted ecological changes with the appearance of modularity. Supposed species may be facultatively modular, with modular ecophenotypes always dominating biohermal settings. However, only genera possessing porous septa show any development of modularity, suggesting that an initially well-integrated soft-tissue is a prerequisite for acquisition of the habit. Increasing integration and simplification of the skeleton can be correlated with an increase in soft-tissue flexibility. Even though high integration, skeletally simple stromatoporoid-like forms developed in irregulars, low integration, branching morphologies were by far the most successful. Irregulars show a strongly progressive trend of increasing modularity right up to the final extinction of the group. This confirms the widespread adaptive significance of integration in clonal organisms. Modular archaeocyaths survived beyond the extinction of most solitary forms, suggesting a relative immunity to extinction presumably on account of ecological response. The solitary nature of many archaeocyaths explains many of their previously supposed apomorphies. Modularity is an advanced condition in sponges and we suggest that paedomorphosis facilitates its acquisition in archaeocyaths. The widespread appearance of low integration modularity in different

lineages of archaeocyaths is suggested to represent adaptation to reef-building settings in areas of relatively high turbulence, sedimentation rate and nutrient levels which may have predominated in the early Cambrian.</ABSTRACT>

76474 <TITLE>Functional analysis of archaeocyathan skeletal morphology and its paleobiological implications.</TITLE>

76475 <SOURCE>Paleobiology 18, 4: 464-480.</SOURCE>

76476 <ABSTRACT>A biomechanical study of archaeocyathan (phylum Archaeocyatha) skeletal construction was undertaken in order to compare its function with that of poriferans. Flume experiments were conducted on three cylindrical, brass models of regular archaeocyathans. Two of these, the porous-septate and aporous-septate models (i.e., possessing septa either with or without pores), represent an ontogenetic series; regular archaeocyathans (phylum Regulares) typically exhibit a

reduction in septal porosity as they grow and many have aporous septa as adults. The third model is aseptate and represents a morphology that is not found in fossil record. All models exhibit passive entrainment of flow during flume testing, a phenomenon on which modern sponges depend for suspension feeding. Flow direction through the models is consistent with predictions of the spongiomorph-affinity hypothesis. The three models behave quite differently, however. The aseptate model is least effective at passive entrainment. Although some fluid exits the top of the central cavity (or osculum), a great deal of fluid is entrained out the top of the intervallum and also leaks out the outer wall. Flow induction from the oscula of the septate models is augmented when compared to the aseptate model. The porous-septate model exhibits slight leakage from the outer wall, and a dye-rich plume exits the top of the intervallum. Alternatively, the aporous-septate model exhibits no outer-wall leakage and no entrainment from the intervallum. These differences in flow pattern between the porous- and aporous-septate models suggest a hitherto unknown function for septa. Imperforate septa prohibit the migration of fluid through the intervallum to the low-pressure, downstream side where leakage occurs. The ontogenetic shift in septal porosity, common to many archaeocyathan species, may be a mechanism by which outer-wall leakage is avoided later in life. Archaeocyathans would have encountered progressively higher ambient current velocities as their height increased through growth. Outer-wall leakage is not a problem at low velocities or small sizes, but leakage becomes serious at higher velocities when tall, adult morphologies are attained.</ABSTRACT>

76565 <TITLE>Water movement in Archaeocyathids: evidence and implications of

- passive flow in models.</TITLE>
76566 <SOURCE>Journal of Paleontology 47, 5: 979-984.</SOURCE>
76567 <ABSTRACT>Archaeocyathid models were tested in a flow tank and low speed wind tunnel to determine if their skeletal structure is adapted for passive flow; that is, flow induced by velocity differences. Fluid movement in these models always proceeded from the outer wall to the central cavity, exiting through the opening of the central cavity. The performance of our models suggests that passive flow may have been an important factor in the lives of archaeocyathids. Furthermore, the size distribution of archaeocyathid fossils is consistent with the size distribution predicted by the model system for passive flow; that is, their height is inversely proportional to current velocity. Unhindered fluid movement requires that the central cavity be free of living tissue and that the pores not be occluded by tissue. Thus the location of living tissue must have been in and around the intervallum. Their large excurrent opening suggests that archaeocyathids utilized predominantly passive flow; in contrast, animals with constricted ex-current openings, such as sponges, utilize predominantly active, pumped flow. However, this distinction is incomplete since many sponges have large excurrent openings while some archaeocyathids have constricted excurrent openings. Thus, no functional discontinuity exists between sponges and archaeocyathids.</ABSTRACT>

76734 <TITLE>Paleoecology of Calcisponges (Inozoans, Thalamid Sponges,
Sclerosponges).</TITLE>
76735 <SOURCE>Acta Palaeontologica Sinica 39, 4: 544-547.</SOURCE>
76736 <ABSTRACT>In Paleozoic calcisponge reefs calcisponges (inozoans,
thalamids, sclerosponges) occurred not only at more than 10m but also
at 0-10m water depth. In Permian and Middle and early Late Triassic
(Carnian) calcisponge reefs, calcisponges were dominant reef-builders,
being the most abundant at 0-10m deep part of the reefs. In
post-Carnian reefs, the 0-10m deep parts were occupied by scleractinian
corals, which won with calcisponges in the ecological competition; that
may account for the extinction of the dominant reef-building
calcisponges of Paleozoic and Middle - early Late Triassic reefs. A

statistic study of mine shows that all calcisponge species of Permian and Middle - early Late Triassic reefs disappeared at end-Carnian and all calcisponges species in late Late triassic (Norian and Rhaetian) are new. The most striking evidences for the shallow water occurrence of calcisponges in Paleozoic and Middle - early Late Triassic reefs are (1) the association of calcareous algae such as Archaeolithoporella, which should live in the shallow photic zone, (2) the occurrence of the cemented framestones which lack micritic matrix but have marine fibrous sparry cements, which indicates the occurrence of wave action. By comparison with the occurrence of scleractinian corals and calcisponges in modern reefs, I assume that calcisponge biolistones (biolistone = bio+lie+stone; composed overturned whole skeletons of main reef-building organisms) and biorudstones (composed of the skeleton fragments of main reef-building organisms) might have formed in a water depth 0-3m; cemented calcisponge framestones (i. e., the calcisponge framestones with sparry cements) formed in 3-10m; micritic calcisponge framestones formed in 10-20m; calcisponge bafflestone formed in 20-30m; calcisponge prebafflestone formed in 30- 40m. </ABSTRACT>

76761 <SOURCE>Paleontologicheskii Zhurnal 1980, 2: 44-51.</SOURCE>

76762 <ABSTRACT>A thesis is put forward that the main function of the pseudosepta in chaetetids lies in the regulation of physiological interrelation between the soft part girth of the polyp and its active surface. This interrelation is reflected by the ratio of calyx diameter and the spatial extension. It is identical in related species and changes slightly in related genera. An evolutionary pattern is proposed based on the colonial architecture and the interrelation of the body volume against the reabsorbing surface.</ABSTRACT>

76786 <TITLE>Relationships between growth-bands and paleoenvironmental proxies Sr/Ca and Mg/Ca in hypercalcified sponge: A micro-laser induced breakdown spectroscopy approach.</TITLE>
76787 <SOURCE>Spectrochimica Acta Part B: Atomic Spectroscopy 62, 12: 1537-1545.</SOURCE>
76788 <ABSTRACT>Long classified as coral hydrozoans, Chaetetids are now considered as a group of very shallow marine hypercalcified sponges. As corals do, they grow by adding calcium carbonate under their pellicular living body in such a rhythmic and regular way that we suspect that sclerochronology is possible, based on the hypothetical annual growth bands of their skeleton. Regarding to its accurate lateral resolution of 5 µm by laser shot, micro-LIBS study was chosen to check its potential for such application. The LIBS apparatus is composed of a microscope coupled with a 266 nm Nd-YAG laser, delivering a 4 mJ-power per shot, and an ICCD camera. The acquisition of the spectra is made via the SE 200 spectrograph, on the large 190 nm to 1100 nm wavelength range. The entire longitudinal thin section of the specimen was analysed from the bottom to the top of the Ptychochaetetes section in a multi-elementary cartography for Ca-Mg-Sr elements. Sodium and Barium were also detected in trace amounts. The Mg/Ca concentrations are mainly between 400 and 600 mmol/mol considering an average value for each profile. This study shows that during the Ptychochaetetes growth, an obvious time-dependent heterogeneity in the chemical Mg/Ca and Sr/Ca composition can be observed. These variations demonstrate the possible use of this method for sclerochronological studies.</ABSTRACT>

76800 <SOURCE>Lethaia 24: 333-346.</SOURCE>
76801 <ABSTRACT>The skeleton begins as a laminar unit with many callicules starting at the same time. Several styles of early growth occur, but the profile remains simple. Similar morphologies develop to those of stromatoporoids, tabulates, colonial rugosans, etc. and are primarily influenced by sedimentation and turbulence. Columnar and branching chaetetids grew in quiet water; laminar and domical, in water of higher energies. Encrusting forms grew in a wide range of environments. No certain relationship can be demonstrated between taxonomy and growth

- form.</ABSTRACT>

76825 <TITLE>Microstructural features of fibrous tissues in the skeletons of some chaetetid sponges.</TITLE>
76826 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 309-315. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
76827 <ABSTRACT>In the first part of this paper, a review of three classical terms ("water-jet", "penicillate", and "trabecular";) used in microstructural analysis is presented. Examination of calcified fibrous tissues encountered in living sponges: the "water-jet" microstructure in a Merlia, and the "penicillate" microstructure in a Ceratoporella is compared with a "simple trabecular" structure (from a scleractinian coral) and leads us to propose criteria for separating these different organizations of skeletal tissues. Application of these criteria to different examples of chaetetid sponge skeletons ranging from Carboniferous to Recent, allows us to modify the usual pattern of their distribution through time. The synchronic changes observed in both mineralogic and microstructural characters are clearly consistent with previous data obtained by study of different "spherulitic" structures in sponges. These results indicate that oceanic conditions inhibit or promote the development of calcified nonspicular skeletons in sponges.</ABSTRACT>

76839 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural,

- Seccion Geologica 92, 1/4: 197-207.</SOURCE>
- 76840 <ABSTRACT>Specimens of Chaetetes (Porifera) in living position generally are oriented with growth directed upward and outward, away from the substrate. This is documented by convex upward growth surfaces denoted by tabulae and growth interruption surfaces, and by numerical increase in tubules from the initial growth nucleus towards the outer surface. Abundant Upper Carboniferous (Atokan) Chaetetes in the Hueco Mountains of West Texas, USA grew predominantly in this orientation, but many specimens grew downward, with the growth surface in contact with the grainstone to packstone substrate. This growth habit is documented by two types of evidence - tubules of some large specimens in growth position grew only downward, or downward as well as upward and laterally, and small, subspherical nodular specimens display concentric growth without attachment surfaces, growth interruption scars and overlapping, cross-cutting growth layers indicative of sequential growth and rotation. Thus, that part of the Chaetetes in contact with the substrate was not killed nor was skeletal accretion interrupted. Growth to and against the substrate suggests either that Chaetetes was capable of efficient organism-wide transport of nutrients, oxygen, and metabolic waste, or that it possessed other novel means of acquiring nutrients, such as heterotrophic symbiosis or direct absorption of dissolved nutrients from substrate pore water.</ABSTRACT>

- 76865 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 399-409.</SOURCE>
- 76866 <ABSTRACT>Skeletons of fossil coralline demosponges of the order Chaetetida exhibit little morphological variability. Differences in growth form are often obvious, but microscopic features are few in number, though highly variable. This skeletal conservatism is well illustrated by the, until now, number of phyla into which chaetetids have been placed. Studies of Carboniferous species, seven from North America and two from Europe, indicate that the two most commonly used variables, tubule (calicle) diameter and tubule (calicle) wall thickness, are not species specific. Additionally, the cross-sectional areas of the tubules (calicles), a more realistic parameter, also fails

to discriminate between these currently recognized species. Intraspecific variability of these parameters is greater than interspecific variability. No doubt some of the observed variability is due to taphonomic (diagenetic) processes. Perhaps some of the variability is linked to the clonality of these simple invertebrates, a life style that has often been overlooked in taxonomic, and other, studies. Available data strongly suggests that perhaps a major amount of the variability noted is phenotypic plasticity (ecophenotypic), resulting from the association between Chaetetes and algal symbionts, and the resulting constraints of latitudinal position and water turbidity. The drastic decrease, possibly demise, of the genus Chaetetes at the end of the Westphalian (Desmoinesian) may be related to the zooxanthellate association and climate warming in the Stephanian (Missourian).</ABSTRACT>

76929 <TITLE>#39;Coralline Spongien#34;. Der Versuch einer
phylogenetisch-taxonomischen Analyse.</TITLE>

76930 <SOURCE>Berliner geowissenschaftliche Abhandlungen E01: 1-352.</SOURCE>

76931 <ABSTRACT>Porifera with secondary calcareous skeletal elements are
observed within all main taxa of the Pinacophora (Calcarea /
Demospongiae) except the Homosclerophorida. within the Hexactinellida,
taxa with calcareous skeletons are missing. The calcified sponges are
normally called #34;sclerospongia, coralline sponges, Pharetronida,
Sphinctozoa, Chaetetida, and Stromatoporida#34;. These different
skeletal types developed independently several times. The ability to
form secondary calcareous skeletons is linked with the cytoplasmatic
Ca²⁺ control and the Ca²⁺ detoxification which is a vital effect of the
cell. The secondary calcium salt skeletons are one possibility to
eliminate the Ca-surplus, and the calcareous skeletons thus are to be
regarded as a metabolic end product. The ability to form a calcareous
skeleton is interpreted as a symplesiomorphy within the Pinacophora and
is part of their basic pattern. It is a typical cryptotypic character
which is developed in certain pinacophoran taxa as autoapomorphies.

76942 <TITLE>Non-spicular biomineralization in demosponges.</TITLE>
76943 <SOURCE>Fossil and Recent Sponges [J. Reitner & H. Keupp (eds)]:
322-340; Springer-verlag, Berlin.</SOURCE>
76944 <ABSTRACT>These sponges form calcareous skeletons 1) by mineralization
of a collagenous matrix (eg. Vaceletia, Calcifibrosponia); 2) through
a secretory pinacoderm (eg. Ceratoorella, Merlia); 3) intracellularly
(eg. Astrosclera). Mineralogy of the skeleton may be a response to
water chemistry changing in the Sandberg cycle. Microstructure of the
calcareous skeleton is likely to have taxonomic significance only at
lower taxonomic categories. The calcareous skeleton is thought to be a
passive response of the sponges to changing environmental conditions.
It can be produced "with relative ease" by these sponges.

76955 <TITLE>Polyphyly of "sclerosponges" (Porifera, Demospongiae)
supported by 28S ribosomal sequences.</TITLE>
76956 <SOURCE>The Biological Bulletin 193, 3:
359-367.www.biolbull.org/cgi/content/abstract/193/3/359</SOURCE>
76957 <ABSTRACT>To test the competing hypotheses of polyphyly and monophyly
of "sclerosponges," sequences from the 5' end of 28S
ribosomal RNA were obtained for Astrosclera willeyana, Acanthochaetetes
wellsi, and six other demosponge species. Phylogenetic relationships
deduced from parsimony and neighbor-joining analyses suggest that these
sclerosponges belong to two different orders of Demospongiae:
Astrosclera willeyana, being closely related to the Agelasidae, belongs
to the Agelasida, Acanthochaetetes wellsi, being closely related to the
Spirastrellidae, belongs to the Hadromerida. These results contradict
the hypothesis that sclerosponges are monophyletic and imply that a
massive calcareous skeleton has evolved independently in several
lineages of sponges.</ABSTRACT>

</SOURCE>
76970 <ABSTRACT>The polyphyletic coralline demosponges possess a calcareous
basal skeleton of 4 major morphotypes. Each has its own phylogenetic
history, with different mechanisms of formation. One extant taxon of
each skeletal type has been investigated, and its biochemical (e.g.,
intracrystalline organic matrix proteins), geochemical (e.g., stable
isotopes), and histological properties described in detail. * The

thalamid vacoletia shows similarities in its skeletal features to extinct archaeocyathid sponges due to the presence of special Ca₂ waste deposit chambers in the lower part of the skeleton. In our opinion this type is phylogenetically the most important one because it represents one possible evolutionary way of Ca₂ detoxification and illustrates one function of basic biomineralization (Ca₂ -detoxification). More sophisticated biomineralization processes are developed in the agelasid *Ceratoporella*, the chaetetid hadromerid sponge *Spirastrella* (*Acanthochaetetes*) *wellsi*, and the stromatoporoid agelasid *Astrosclera willeyana*. Each of these taxa shows a distinct process of formation with a unique composition of its intracrystalline organic matrix and geochemical features, here characterized in detail. A model of phylogenetic relationships and grades of development is proposed. * The first metazoans with CaCO₃ biomineralization were the worm like Cloudinidae from the late Sinian, which form a tube with a foliated structure. However, the taphonomy controlled mode of basal skeleton formation in Archaeocyatha and Vacoletidae is the most ancient type of biologically controlled metazoan biomineralization. In general, basal skeletons of coralline sponges represent the simplest biologically controlled mineralization, intermediate between biologically induced type (e.g., organomineralization) and the fully enzymatically controlled mineralization of higher Metazoa. 77163 <TITLE>Remarks on the classification system of the Heliolitida.</TITLE>
77164 <SOURCE>Palaeoworld 19, 3-4: 268-277.</SOURCE>
77165 <ABSTRACT>The concept of the sum of common features has been used in order to compare the Heliolitida with the Tabulata and Rugosa and determine the position of Heliolitida in the classification system of Palaeozoic corals. Such morphological characters as the number of septa, septa of the second order, epitheca, coenenchyme and multiplicity by four have been considered. Coenenchyme is present in many taxa and there are no more compelling reasons for the integration of Heliolitida and Halysitida than for the integration of Heliolitida with other taxa containing coenenchyme. The dynamics of some features shows that the differences between three main groups of Palaeozoic corals are within the limits of variation of relative organisms. A high degree of similarity testifies to the close relationship of the Heliolitida and the different qualitative and quantitative expression of similar features testifies to their early divergence from a common ancestor and subsequent independent evolution. Asto-phylogeny and morphological homogeny of all Heliolitida confirm their evolution as a separate, unitary group. Heliolitida is a monophyletic group of corals that is equal to the Tabulata and Rugosa in rank. A common origin requires that the orders should be united into one subclass Paleosclerocoralla of the class Anthozoa. [original abstract] </ABSTRACT>

77178 <ABSTRACT>Some investigators consider that increase of quantity of coenenchyme and decrease of number of corallites appeared in all Heliolitida. But study of concrete lines of development shows that density of corallites in coenenchyme of ancestors is in accordance with the density of corallites in coenenchyme of derivative forms. Increase of quantity of coenenchyme are only particular cases of morpho- and phylogenesis. Concrete lines of development of Heliolitida from Lichenariida not established still and their morphology not explained to characteristic features of Order Heliolitida.</ABSTRACT>

77215 <TITLE>New advances in study of Heterocorals.</TITLE>
77216 <SOURCE>Acta Palaeontologica Sinica 31, 4: 489-500.</SOURCE>
77217 <ABSTRACT>Recently, the writers collected abundant materials of heterocorals from some places in Guizhou and Guangxi, with some advances in the study of the Heterocorallia proposed as follows: 1. Two or three septa were first found in the heterocorals. There are only two septa, in the earliest stage of individual development, there are 3, 4, 5, 6 and even more than 6 septa in the later stage. 2. New septa were inserted in the four original interseptal loculi. The septa extend from the theca to the axis and attach the preceding septa at their ends. They are arranged in bundles and may be developed on the auloslike tube in the central area of the corallite. Based on the different numbers and system arrangement of the septa, six septal models in the evolution of heterocorals may be recognized. [first fragments of extensive summary]</ABSTRACT>

77241 <TITLE>Septal variety and classification of Heterocorallia.</TITLE>
77242 <SOURCE>Journal Changchun Univ. Earth Sci. 26 [spec. issue]: 7-11.</SOURCE>
- 77243 <ABSTRACT>Since the discovery of new heterocoral with 3 septa, the septal variety of the different genera of heterocorals has been clearly revealed. According to the developmental model of the new septa, the heterocorals can be divided into two types, one with fossula and the other without fossula. The fossula - bearing type can be developed from the genus Triphyllia with 3 septa to the genus Pentaphyllia with 5 septa and furtherly to the genus Fossaphyllia of multisepta. The non-fossula type can be developed from the genus Quadratiphyllia with 4 septa to the genus Hexaphyllia with 6 septa and furtherly to the genus Heterophyllia with multisepta. Besides, the family Crepidophylliidae with the aulos structure and the family Longlinophylliidae with special wall structure have been found. This paper has suggested a systematic classification of the known 19 genera of the heterocoral, and placed the Heterocorallia as subclass of the Anthozoa which is equivalent to the subclass Rugosa.</ABSTRACT>

77280 <TITLE>On the origin of Hexasterophora and Amphidiscophora (Hexactinellida). A further discussion of their phylogenetic significance.</TITLE>
77281 <SOURCE>FC&P 19, 2.1: 13-15.</SOURCE>
77282 <ABSTRACT>Mostler (1986) published a rich collection of Paleozoic hexactinellid spicules from different localities of the world. We want to draw the attention of spongiologists to this publication, because it has been practically ignored so far (maybe due to the fact that they were published in a geological journal). It can be shown that the main taxa of living hexactinellid sponges (Hexasterophora and Amphidiscophora) can be traced back even to the Cambrian. [...] The fact that Hexasterophora and Amphidiscophora are very old in origin, and that they have been developing independently at least since the early Paleozoic, of course does not infer that the Hexactinellida are polyphyletic in origin. The Hexactinellida are a well-established monophylum. [excerpts from the short note]</ABSTRACT>

- 77307 <SOURCE>Senckenbergiana biologica 82, 1/2: 1-10.</SOURCE>
77308 <ABSTRACT>Cyathella is a monospecific hexactinellid sponge genus, whose systematic position within the Hexactinellida has been so far unresolved. The original material of the type species, *C. lutea* Schmidt 1870, which has been reexamined, is here re-described and the genus is revised. The dictyonal skeleton of *C. lutea* is investigated, and a new sub-family Cyathellinae is erected to comprise this special type of skeletal architecture. *C. lutea* is compared with fossil hexactinellid species attributed to this new sub-family. </TITLE>
77359 <SOURCE>Senckenbergiana lethaea 59, 4/6: 275-327.</SOURCE>
77360 <ABSTRACT>Several new types of conulariid septa are described. They grew in adapertural direction with the growth of the animal, supported mesenteries, and served for the attachment of longitudinal muscles. One septal type indicates the presence of peristomial pits. Cessation of septal growth, followed by the onset of new septal portions, is interpreted to have been caused by processes linked with strobilation. From observations made on skeletal structures, the conulariid animal, a true scyphozoan, is reconstructed. Its relation to the Scyphomedusae, in particular to test-bearing scyphopolyps, is discussed. * Conical conulariid tests with a circular cross-section, recovered from Silurian and early Devonian strata of New South Wales, are placed in the new suborder Circonulariina. It comprises one new family, two new subfamilies, four new genera, and five new species that are described. [original summary]</ABSTRACT>

77371 <TITLE>Phylogenetic implications of calcium carbonate mineralogy in the Stylasteridae (Cnidaria: Hydrozoa).</TITLE>
77372 <SOURCE>Palaios 7: 96-107.</SOURCE>
77373 <ABSTRACT>The carbonate mineralogy of this calcified hydrozoan family is controlled largely by phylogenetic rather than environmental factors. X-ray diffraction analysis of 24 of 25 genera (almost the entire family) indicate that the skeletons of most species analyzed (54 species in 20 genera) were aragonite; only 7 species in 4 genera were calcite. In addition, several species contained coexisting polymorphs: 7 calcitic species with traces of aragonite; 1 aragonitic species with traces of calcite and 2 species with variable percentages of both polymorphs, which is dependent on the distance from the growing tip. Mole % magnesium carbonate in the calcite ranged from 6.5 to 10.0, but had no correlation to any known variable. Likewise, no correlation was found between polymorph type and any morphological or environmental variable, except for a generalized temperature effect, wherein genera with calcitic coralla are restricted to water colder than 13°C; aragonitic coralla occur at temperatures from -1.5 to 30°C. However, there is a close correlation of the polymorph type to the generic phylogeny of the family, according to the cladogram.</ABSTRACT>

77384 <TITLE>Phylogenetic relationships of desma-bearing demosponges (Porifera, "Lithistida").</TITLE>

- 77385 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 293-297.</SOURCE>
- 77386 <ABSTRACT>The Lithistida sensu Schmidt (1870) are a polyphyletic group of sponges. They were separated because of their special morphologic criteria: the desmata, a peculiar type of spicule. In the fossil record they range from the Middle Cambrian to Recent. Based on phylogenetic characters the desma-bearing demosponges are divided into monophyletic groups. It is obvious that the character desmata must have been a plesiomorphic feature for all demosponges. The main characters used for defining relationships are the different microscleres (aster-bearing forms and sigma-bearing forms), the skeleton architecture and the larval strategy. A possible phylogenetic relationship shows a monophylum Aster - Tetractinellida - Hadromerida pars and a monophylum Ceractinomorpha pars - Halichondridae generic groups (after van Soest et al. 1990).</ABSTRACT>

77475 <TITLE>Rugae und wachstumszonen bei Korallen.</TITLE>

77476 <SOURCE>Paläontologische Zeitschrift 51: 117-130.</SOURCE>

77477 <ABSTRACT>Rugae are more or less horizontal, fine ridges of the epitheca of corals. Therefore, they are rare in modern scleractina who seldom have an epitheca. Following the studies of Barnes (1972) the

rugae are a sign for the daily increment of the skeleton. Besides the rugae there are also other zones of growth. They are shown by the radiography as an alternation of dark and light bands. These zones of different density are interpreted as a seasonal change of zones of different thickness (? and arrangement) of trabeculae. It seems possible that there is also a monthly rhythm of the growth the causes of which are unknown. * In rugosa there are rugae in solitary corallites as well as in colonial coralla. The rugae of the cerioid specimen of *Columniphyllum sulcatum* described by Quenstedt 1879 have a width up to 0,3mm. In spite of this unusual width it seems probable that these rugae are also the product of the daily increment. * The difficulties of interpretation, identification and combination of rugae in determined time periods are great handicaps for their use as geochronometric clocks. But with more knowledge about the growth of recent corals in regard to the diverse factors of the environment, the rugae would be a possible important feature for paleologic evidences. 77490 <ABSTRACT>It is demonstrated that two stages are existing in the evolution of rugose corals. During the first stage (Proterozoic time - Early Ordovician) the polyps were lacking a skeleton but during the second stage (Middle Ordovician - Permian) they obtained the ability in building a skeleton. Regarding their taxonomy, it is proposed to classify them into two orders of the subclass Tetracorallia: the Rugosa and the Heterocorallia.</ABSTRACT>

77516 <ABSTRACT>Cotton has provided in his book a second great service to rugose coral workers. Having previously published an index with supplements to the rugose coral genera, he has now compiled a guide to the locations of original descriptions of rugose coral species. In the first section species are listed alphabetically under the genus to which they were originally or have been subsequently referred, the genera also being listed alphabetically. In the second section all species are listed alphabetically followed by the genus under which they were originally described only, together with author and date. The book concludes with a list of references. [extract from a book-review by C. T. Scrutton]</ABSTRACT>

77527 <TITLE>Application of mathematical methods to classification of Tetracorals.</TITLE>
77528 <SOURCE>Chinese Academy of Geological Sciences Bulletin 1983, 5: 71-79.</SOURCE>
77529 <ABSTRACT>Although Tetracorals have formed the object of specific study for two hundred years, the results of previous investigations show certain degree of incongruity due to different personal experiences and different viewpoints. While identifying and classifying similar genera and species, it was not uncommon to emphasize a certain character and ignore other features to such an extent that even individual variations were mistaken for specific variations thus artificially increasing the number of new taxa and causing confusions in the taxonomy of corals. In this paper, four genera -- Yuanophyllum, Lophophyllum, Koninckophyllum and Arachnalsna – are studied by means of multivariate methods; namely: theory of quantification transforming the descriptive features into qualitative variables; characteristic analysis selecting variables; correspondence analysis and discriminative analysis distinguishing the different genera and ascertaining a mathematical model of classification. It is concluded that Arachnolasma is apparently independent, Koninckophyllum and Yuanophyllum have common transitional forms which show their affinity close to Lophophyllum and Yuanophyllum are different evolutionary stages of the same series and, finally, that Lophophyllum is by no means an independent genus. 77631 <TITLE>Some remarks on diagenesis of rugose coral skeletons.</TITLE>
77632 <SOURCE>Geologos 6: 89-109.</SOURCE>
77633 <ABSTRACT>Rugose coral microstructure exhibits striking similarity to that in Scleractinia. The main difference lies in the mineral composition: calcitic in the former and aragonitic in the latter. Calcitic skeletons of the Rugosa are commonly better preserved than those in the Scleractinia, and therefore some of them have been interpreted as unaltered, a position rejected in this paper. The dual nature of septa, which commonly consist of a primary trabecular septum and secondary fibrous sheets, results in differently expressed diagenetic alteration in comparison of other structural elements. It has been postulated that both early and advanced diagenesis may, in some

circumstances, bedistinguished in the Rugosa. In most instances the early diagenetic features were destroyed by thepost-burial alterations. Replacement and recrystallization are the most important processes amongthe advanced chemical alterations. Both may either facilitate the recognition of original macro- andmicrostructures or obscure them Surface replacement by silica promotes perfect preservation ofshape and inner morphology, whereas pervasive replacement my destroy both. Selectedreplacement by hematite may help in exposing the trabecular microstructure of septa, whereas deepreplacement may destroy the entire morphology. Physical alteration, such as crushing and flatteningof skeletons are always destructive. The result from compaction, and their scale depends on skeletalmorphology and on the relationship between the rate of infilling of intra-skeletal spaces and theaccumulation of surrounding sediment.Pre-burial events, such as overgrowth and penetration by borrowing organisms, their holdfasts orroots may aid in the recognition of early diagenesis, but may also led to substantial pre-or postburialskeletal alteration, resulting sometimes in total destruction. This depends mostly on the pH ofpore fluids.</ABSTRACT>

77644 <TITLE>The systematic position of the solid column of Rugose corals.</TITLE>

77645 <SOURCE>Acta Palaeontologica Sinica 38, 2: ... [pp?].</SOURCE>

77646 <ABSTRACT>The systematic position of the solid column of Rugosa has been a controversial issue for a long time. The solid column consists of fibrous tissue and clearly differs from the axial column or protoaxial column. Its axial structure has no relationship with the cardinal septum or counter septum and inner ends of the septa. It is an indepently developed structure in the rugose coral. So, the Rugosa with solid column could constitute a new order - Cyathaxoniida ord. nov. According to the unique fibrous tissue and the shape of solid column, this order could be further subdivided into three families: Cyathaxoniidae Edwards & Haime, 1850, Amygdalophyllidae Grabau, 1935, and Ekvasophyllidae Hill, 1981. There are abundant solid column corals in Early Carboniferous of China. In this paper, three genera (including 1 new genus) and five species (including four new and 1 uncertain species) are described. They were found from Datangian to Early Carboniferous in Qinghai and Yunnan provinces. [original summary]</ABSTRACT>

77657 <TITLE>Homoemorphy and levels of generality in Rugose corals (Anthozoa, Rugosa).</TITLE>

77658 <SOURCE>Journal of Comparative Biology 3, 1: 103-108.</SOURCE>

77659 <ABSTRACT>Homeomorphy has been considered as one of the chief problems in rugose systematics because it affects the whole form of the organism, in contrast to homoplasy that acts only against some

features. However, it is observed in traditional rugose systematics that all features used to diagnose forms are also usually employed to define groups of different levels of universality. That practise leads to a situation where many characters appear more than once in related and unrelated groups causing a false feeling of homeomorphy as the main process acting during the development of the Rugosa. In an attempt to observe order in this group, it should be observed that characters of higher generality be used to define larger groups while those of lower generality be employed at lower levels of universality. Characters like form of the coralla, in colonial forms, or corallite shape, in solitary forms, are fitted to define groups immediately after the great group Rugosa, that is, suborders or maybe families, but they cannot be used at specific level since they are of higher order. The same can be said of some skeletal elements like tabulae, dissepiments and axial structure in general. The derived states of those characters can only be used to define groups, in lower level of universality, after proved to be synapomorphous among them. Using of non-biotic data, like stratigraphy and biogeography, to test trees can just be accepted when used a posteriori. An example of character distribution is presented with some Carboniferous rugose corals from the Siphonodendron-group.

77683 <TITLE>Zigzag microstructure in rugose corals: a possible indicator of relative seawater Mg/Ca ratios.</TITLE>

77684 <SOURCE>Geology 30, 5: 415-418.</SOURCE>

77685 <ABSTRACT>Low-Mg calcite (LMC) and high-Mg calcite (HMC) have been identified confidently as original biominerals in different rugose corals. Devonian Tabulophyllum had a LMC skeleton, whereas Pennsylvanian Lophophyllidium had a HMC skeleton. Zigzag microstructure, a diagenetic microstructure in rugose corals, may be related to early migration of Mg²⁺ ions during transformation of HMC into LMC. Therefore, zigzag microstructure may indicate that the original mineral was HMC even in specimens that subsequently converted to LMC. Stratigraphically, corals with zigzag microstructure are confined to the late Paleozoic, which is coincident with the " aragonite sea" of P.A. Sandberg. Hence, fluctuating Mg/Ca ratios may have directly controlled oscillations in marine carbonate chemistry and the mineral composition of rugose corals so that HMC skeletons (as indicated by zigzag microstructure) formed during intervals with "

- aragonite seas" and LMC skeletons (e.g., Tabulophyllum) formed during intervals with "calcite seas".</ABSTRACT>

- 77697 <SOURCE>Palaeontology 45, 4: 671-687.</SOURCE>
- 77698 <ABSTRACT>Among the Rugosa operculae were developed by only few genera. One is the slipper-shaped Calceola and another is the pyramidal shaped Goniophyllum. On the basis of biological and morphological knowledge of recent corals, the two different bauplans of the soft bodies of Calceola and Goniophyllum have been reconstructed. The soft body (i.e. the polyp) of a rugose coral is thought to have all the basic structures of anthozoan polyps: a barrel-like body shape, a flat oral disc with tentacles, and the mouth from which the pharynx reaches inside the gastric cavity. Furthermore, as in all Anthozoa, Rugosa had internal mesenteries that act as tensile cords; during growth in diameter further mesenteries were inserted. In contrast to all other Anthozoa, in the Rugosa new single mesenteries were added in four insertion sectors. The bauplans of Calceola and Goniophyllum differ in the pattern of mesentery insertion into these four sectors. Calceola had a serial, insertion pattern and Goniphyllum had a symmetrical insertion pattern. They are representatives of the two different bauplans within the Rugosa. The lid corals are examples of convergence evolved genera; Calceola as well as Goniphyllum originated by quite simple modifications of the ancestral type. The peculiar shapes, the operculae and especially the straight hingers between the calyx and the lid(s) result only from mechanical necessity. Under special conditions (such as high sedimentation rates) these modifications of the corallum represent suitable tactics for survival.</ABSTRACT>

- 77710 <SOURCE>Coral Research Bulletin 7: 167-173. [Dieter Weyer's 65th birthday commemorative volume; S. Schröder, H. Löser & K. Oekentorp (eds)]</SOURCE>
- 77711 <ABSTRACT>Interstitial tabellae developed in very narrow interseptal loculi (0,04-0,06 to 0,2-0,3 mm) resulting in a large amount of thickening of septa. They occur commonly in genera developing septal stereozones and are described here in six Lower Carboniferous species: Siphonophyllia cylindrica hasteriensis, S. rivagensis, Uralina gigantea, Keyserlingophyllum obliquum, Caninophyllum skouraense and Eocaninophyllum yitzanghense. They differ from tabulae which develop usually in wider interseptal loculi by their higher density (from 3-5 up to 10-20 times more numerous) and more complex and various patterns. The minimum widths (0,04 to 0,06 mm) for the interseptal loculi

allowing their construction and therefore the presence of the folds of the body wall, provide insight into the thickness of the wall of the polyp, but raise the question if there would remain enough space to allow the presence of mesenteries in the lower part of the gastrovascular cavity.</ABSTRACT>

77774 <TITLE>On the taxonomic position and evolutionary trend of Pilophyllia
Ge et Yu, 1974.</TITLE>
77775 <SOURCE>Bulletin Chinese Academy geological Sciences 12: 95-103.</SOURCE>
77776 <ABSTRACT>The diagnosis of the genus is supplemented in terms of septal
type and minute skeletal structures. The septa of Pilophyllia are
clearly amplexoid, and are composed mainly of lamellar sclerenchyme in
the proximal part of the corallum, but are characterized by development
of trabeculae in the upper part. The outer part of the septa in the
peripheral stereozone are thick and contiguous, containing stout
rhabdacanth trabeculae invested with lamellar tissue. The septa grow
suddenly thin beyond the stereozone, but still comprise rhabdacanth
trabeculae that are developed upon the successive tabular floors. The
clear boundary and evident difference between the juxtaposed and
well-preserved lamellar and fibrous tissue as seen within the septa
indicate that the idea of secondary origin of the lamellar structure of
the skeleton is not tenable. * There are altogether 14 species and
subspecies of the genus, among which, the three new ones, Pilophyllia
simplex Chen, P. alternata Chen and P. densitabulata Chen are described
here. Only three species occur in the Lower Silurian. A comparison of
the various species show that a clear tendency existed for the fibrous
structure, i.e. the trabeculae, to develop at the expense of lamellar
structures at higher horizons (pI. II, fig. 1-4). Other evolutionary
trends include thickening of the septa and increasing width of the
stereozone. * On the basis of skeletal structures, Pilophyllia is
attributed to Family Amplexidae, which is characterized by amplexoid
septa and progressive development of fibrous skeletal structures. Two
groups may be recognized in the family, a primary group dominated by
the lamellar tissue of septa throughout, including Amplexoides,
Lindstroemophyllum, probably also Zelophyllum and the Late Ordovician
compound form Crenulites, in addition to the Carboniferous Amplexus and
Bordenia, and an advanced group with a progressive development of
trabeculae septa, including Pilophyllia and Protopilophyllum. The
Devonian Siphonophrentis and Heterophrentis with complete septa may not
be included in this family.</ABSTRACT>

77800 <TITLE>Los corales rugosos y el uso de indices de semejanza Faunistica en Estudios Paleobiogeograficos.</TITLE>
77801 <SOURCE>Paleontologia i Evolucio 20: 297-307 [in Spanish].</SOURCE>
77802 <ABSTRACT>Los corales rugosos constituyen un grupo que puede ser de gran utilidad en estudios paleozoogeograficos. Sin embargo, su uso en estudios comparativos de diferentes cuencas ha de hacerse con precauciones, debido al distinto nivel de conocimiento de cada area. Esto que puede ser un inconveniente en ciertos casos, permite, sin embargo, hacer un analisis de la validez y de las cualidades de algunos de los numerosos indices que han sido definidos con el objeto de comprobar la mayor o menor relacion faunistica entre diversas areas por media de la presencia o ausencia de taxones. Se han recopilado mas de cuarenta indices, entre los que se han seleccionado doce que se han utilizado para realizar matrices de semejanza entre las diversas areas. Las zonas seleccionadas son generalmente aceptadas como divisiones zoogeograficas en la paleogeografia del Moscoviense, que es el periodo elegido para este analisis, aunque su extension es muy variada. Los resultados de la aplicacion de estos indices muestran la relatividad de su uso, y la necesidad de fijar unos objetivos previos a la seleccion del modulo de comparacion en cualquier estudio biogeografico.</ABSTRACT>

- 77893 <ABSTRACT>A SEM study of Aulophyllum fungites (Fleming 1828) reveals that both the longitudinal and transverse structure of the skeleton is fibrous in nature and is composed of calcite needles. The needles are

of two sizes, those composing the septa and tabellae show an average length of 32 μm and those forming the dissepiments, axial tabellae and column septa (lamella), 10 μm and 2 μm respectively. Within the septum, only one series of slender trabeculae develop along the axis, with an average diameter of 30-60 μm , while the lateral parts are composed of long, subparallel needles, some of which being grouped into tufts. No clear boundary exists between the axial and lateral parts. Clear growth-lines are evidently continuous across the connecting parts of adjacent septa and tabulae. This means that skeletal structures in both elements are synchronous and syntaxial in nature. </ABSTRACT>

77945 <ABSTRACT>The type material of the Tournaisian Zaphrentis calyculus from the Miller's (1891) collection, redescribed by Easton (1944) has been re-investigated. The better preserved specimens are assigned to 5 species and 5 genera (among them Rotiphyllum diutinum sp. n., Petraia (?) milleri sp. n. and Patularima gen. n.). Some forms are described in open nomenclature. The taxa are discussed in terms of morphology, ontogeny, intraspecific variability and relationships. Environmental and / or genetic control of straight, widely-flaring and horn shapes and of stereoplasmic infilling is discussed.</ABSTRACT>

77957 <SOURCE>Acta Palaeontologica Polonica 34, 1: 3-46.</SOURCE>
77958 <ABSTRACT>Detailed study of the holotype and topotype of the type species of Trochophyllum Milne-Edwards and Haime reveals that this genus has a unique internal morphology most similar to Neaxon Kullmann. Although the systematic relationships of small, aulate solitary corals remain dubious, Trochophyllum is referred provisionally to the family Petraiidae de Koninck. The genus is represented by the type species, T. verneuillanum Milne-Edwards and Haime, and the informal taxon T. sp. 1, which are known only from Tournaisian (early Osagean) strata in Kentucky and Indiana, USA. Previously published records of Trochophyllum outside the type locality of its type species are either invalid or unconfirmable on present published information. Trochophyllum is distinguished by a highly variable aulos that is typically of the stereotheca-type, filled with stereoplasm at maturity; axial tabulae absent or not preserved at maturity; cardinal septum shortened in the calice; and minor septa developed only as foundations.</ABSTRACT>

78008 <TITLE>Microskeletal structures of the genus Lophocarinophyllum with a discussion on the family Lophophyllidiidae.</TITLE>
78009 <SOURCE>J. China Univ. Geosc., Earth Sci. 15, 3: 257-262. [in Chinese, with English summary]</SOURCE>
78010 <ABSTRACT>Among the family Lophophyllidiidae Moore et Jeffords 1945, Lophocarinophyllum Grabau 1922 possesses well developed septal flanges. The microskeletal structures of the septa are either composed of distinct monacanth trabeculae with clearly radiating needles, or of an axial zone of irregular slender trabeculae with diverse needles and lateral zones with subparallel needles or tufts. The flanges have slender trabeculae in the axial zone and parallel needles in the lateral zones, but no regular trabeculae with radiating needles were observed. In several specimens of Lophocarinophyllum acanthiseptum collected from the Upper Carboniferous in the North China, weakly developed convex tabulae are present. Thus it may be held that the genotype is possessed of tabulae, and the genus Lophotabularia Shi, established on the presence of tabulae, may better be considered as a synonym of Lophocarinophyllum. So far 8 species of Lophocarinophyllum, L. acanthiseptum Grabau, L. major Heritsch, L. yakovlevi Fomichev, L. karpinski Fomichev, L. suetomi Minato, L. lophophyllidium Liao et Xu and L. abnome Shi may be recognized, including the new species L. stereoseptum described herein. In our revised classification of the rugose corals (Wang et al 1989), 10 genera were assigned to Lophophyllidiidae, but Lophophyllum was tentatively included therein.

Actually the latter genus (genotype *L. konincki*) is a monozonal coral of zaphrentoidid affinity probably akin to *Claviphyllum* and may therefore better be transferred to the family *Bradyphyllidae* under the suborder *Zaphrentitoidina*. Thus the family *Lophophyllidiidae* includes 8 genera: *Lophophyllidium* Milne-Edwards et Haime, *Sugiyamaella* Yabe et Minato, *Lophocarinophyllum* Grabau, *Stereostylus* Jeffords, *Neostereostylus* Lin, *Tlmorphyllum* Gerth, *Lophamphylus* Moore et Jeffords and *Paralophophyllidium* Lin.

78023 <ABSTRACT>There have been diversified views on the systematic significance of the rugose coral's minute skeletal structure. In this work attempt is made through the microstructures of the typical genera of 14 families to reveal the value for the systematic Rugosa of the Carboniferous period, with only a species of Siphonophyllia from the Lower Carboniferous of the Qilian Mountain described as an example.</ABSTRACT>

78048 <SOURCE>Hydrobiologia, 216/217 [Williams R.B., Cornelius P.F.S., Hughes R.G. & Robson E.A. (eds): Coelenterate Biology: Recent Research on Cnidaria and Ctenophora]: 413-418.</SOURCE>
78049 <ABSTRACT>It has been suggested that the septal furrows in the Palaeozoic rugose corals are secondary in comparison both to growth lines and to the septal blades inside calices. The leading role of furrows as an indicator of septal increase is thus questioned. Septa

are always grouped in quadrants but their increase is generally towards the cardinal septum. The arrangement of the contratingent minor septa seems to be independent of the increase in septal furrows. Hence, the growth of the polyp's skeleton may have started from an aseptal cup.

- 78114 <ABSTRACT>Rugose coral taxonomy is based on morphological features which vary in reliability for taxonomic purposes. Microstructures are interpreted as having a calcitic origin and only faintly altered by diagenesis. Thus fibro-normal and trabecular septal structures as well as septal dilations are important taxonomic features. The presence or absence and type of holdfasts and genuine fossular structures reveals special modes of life strategies and are also very important taxonomic signatures. Biometry must be critically applied as intraspecific variation and is dependent on various life strategies and ecological influence.</ABSTRACT>

- 78140 <ABSTRACT>Different types of "third order" septa are fairly widely distributed among Rugosa in addition to major septa (protosepta, metasepta) and minor septa (catasepta). The initial standard septal

apparatus of Middle Ordovician time included hyposepta, which are recorded from 32 species of 12 suborders during lower Caradocian to Serpukhovian and became steadily less abundant from the Caradocian to their final disappearance in the late Palaeozoic. Hyposepta (based on the Givetian *Stereolasma rectum* (Hall 1843) appear as a very small third septal cycle (only active at the upper calicular margin), intercalated between all major and minor septa, and best discernible from special weaker septal furrows on the external archaeotheca. The term diplosepta [based on the Ludlowian *Sutherlandinia petaloides* (Ball & Grove 1940)] refers to major and minor septa, which bifurcate at the periphery of the upper calice (but always originate from only one septal furrow of the wall). This specialization affects one (counter) or nearly all septa, and characterizes mainly the Silurian-Devonian Ditoecholasmatinae and Sutherlandiniinae, and some Lower Carboniferous pleonophorous taxa (Cyathoclisia). </ABSTRACT>

78151 <TITLE>Borings, embeddings and pathologies against microstructure. New evidences on the nature of the microstructural elements in rugose corals.</TITLE>

78152 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 99-116.</SOURCE>

78153 <ABSTRACT>The principal aim of the present study has been to consider the moment of production of the different skeletal anomalies (borings, embeddings and pathologies) for obtaining an accurate datation of the affected microstructures. The use of this textural criterion has usually been accepted in those research studies interested in the moment of production of the texture, such as carbonate petrology and genesis of submarine cements. The material studied in this report comes from the collections of solitary rugose corals without dissepiments, from Upper Visean of Northwestern Ossa-Morena region (Los Santos de Maimona and Guadiato Basin) except some specimens supplied by Prof. J. Kullmann from the Emsian of Bostanci at Istanbul (Turkey) which are totally recrystallized and previously drilled as well. This study is based on the occurrence of three kinds of evidences: Borings: Boring action penetrates and dislodges coral structures, providing a source for dating, since boring action must be posterior to these structures. Its study is based on the analysis and the interpretation of morphology of borings, and also it is completed with the description of their borders, and the different alteration processes which occur in this areas. Embeddings and pathologies: Both anomalies are contemporary with the biocrystallization, generating borders with concordant microelements. Description of complete diagenetic alterations in drilled specimens and comparison with the described borders. The possibility of describing rugose corals perforated and totally recrystallized (i.e. with a previously well known microstructure) constitutes finally an excellent reference for comparing the realized observation in the other paragraphs.</ABSTRACT>

78164 <TITLE>Evaluation of rugose coral potentials as index fossils.</TITLE>
78165 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 303-309.</SOURCE>
78166 <ABSTRACT>Rugose corals were epifaunal benthos, most profuse and diverse in carbonate perireefal and reefal environments. Like modern scleractinian corals they were sensitive to several ecological factors like water temperature, depth, salinity, bottom conditions, nutrient supply and probably illumination. Rugose corals showed highest diversity in subtropical and tropical realms. In cooler realms their diversity was low and solitary lambelasmatic forms dominated. At different times plate movements have brought the continental plates with including shallow sea areas into different climatic zones. This has often caused successions of different coral provinces on the various plates. Areas with overlapping faunas between these plates are often difficult to find. Rugose corals are mainly useful for correlation on the stage level within the same confacies belt as most species are comparatively short-ranging. Correlation based on Baltoscandian rugose corals from Rarhthyan - Hirnantian times clearly indicates that very few species cross sharp lithofacial boundaries. Morphologic trends observed in the succession of rugose coral assemblages give valuable support to a more reliable biostratigraphy. In order to improve the possibilities of using rugose corals as biostratigraphical tools we need more detailed and uniform taxonomic descriptions and more information about the strata where these taxa are found. Regular workshop meetings where taxonomic problems can be discussed by specialists are highly recommended.</ABSTRACT>

78177 <TITLE>Konstruktionsmorphologische Rekonstruktion rugoser Korallen.</TITLE>
78178 <SOURCE>Profil 11, 325-340.</SOURCE>
78179 <ABSTRACT>The rugose corals known from the Paleozoic era are comparable to the skeletons of fossil and recent scleractinians. The reconstruction of the rugose soft body is based on the assumption that polyp-like organisms produced the skeletons of the rugosa. Analyzing the construction of anthozoan polyps indicates a conception of a general soft body for coral polyps. This soft body is characterized by hydraulic filling, by tethering, and by internal mesenteries as well as by tethering and fixing of a valve-like collapsible tube. Tentacles could emerge between the mesenteries on the oral disc. The external epithelial layers of the pedal disc are able to produce external carbonate structures between the mesenteries. During the ontogenetic growth of polyps, the installation of a new internal tethering structure is necessary to preserve form and coherence of the whole construction. Thereby new spaces between the mesenteries arise in which new carbonate structures were produced. Therefore, the skeleton of a coral polyp represents a kind of negative copy of the internal construction of the soft body. Thus the fossil skeletons give some valuable hints for the reconstruction of their soft bodies. The rugose corals are reconstructed as polyp-like barrel-shaped constructions. Their shape is determined by hydraulic filling and by the internal tethering by single mesenteries. The given reconstruction of the

ontogenetic insertion of single mesenteries explains the pattern of the septal insertion within only four sectors in the rugose skeletons. This reconstruction is only valid for the general representation of the rugosa. It is a testable approach to the reconstruction of the rugose soft body, and it explains the pattern of septal insertion of the rugose corals. The reconstruction presented here is not extended to the very early ontogenetic stages of rugose polyps. Obviously, the model should be modified to explain those groups of the rugosa which do not show the general pattern of septal insertion in four sectors. </ABSTRACT>

78190 <TITLE>On genus Stylostrotion Chi and its systematic position.</TITLE>

78191 <SOURCE>Acta Palaeontologica Sinica 35, 1: 84-87.</SOURCE>

78192 <ABSTRACT>After the establishment of the genus Stylostrotion by Dr. Chi in 1935, many palaeontologists in China and abroad have different opinions. As Chi described in diagnosis of this genus: "It has a distinct palicolumella"; some palaeontologists, such as S. Smith, D. Hill, Yu and Wang, regard it as a synonym of the genus Siphondendron. However, J. Fedorowski established a new subclass Dividocorallia (Palaeozoic Anthozoa) in 1991, holding a different opinion from Chi about this genus. He indicated the inconstant number of major septa in quadrants, which are similar to that of heterocoral, and so he established the new family Stylostrotionidae, which belongs to the order Calyxcorallia under the subclass Dividocorallia. Through examining the description and figures of this genus in Chi's paper, the authors found that there are two individual transverse sections in the type specimen (Pl. I, fig. 1a), with a palicolumella-like structure at the center of the right one. In fact, this is a structure caused by the connection of inner septa, rather than a palicolumella; the left one also presents this characteristic, with its septa in bunchwise arrangement, and each bunch has a long septum prolonged to the center and connected to others. Hence, it may be concluded that this genus has no palicolumella and bears no relationship with Siphonodendron. It is unavailable to correlate the genus with Nemistium, Aulina, Diphyphyllum, and therefore it is necessary for us to emend the diagnosis of the genus in this paper. According to Fedorowski (1991), this genus is a kind of heterocoral, and is regarded as a new Palaeozoic anthozoan. However, the authors have a different opinion, since the heterocoral has a specific structure, which is characterized by the never separated inner ends of septa, the absence of minor septa and dissepiments, with some boss, spines and ridges on the wall. While this genus has minor septa and a dissepimentarium, with the inner ends of septa occasionally separated, indicating that it is a typical Rugosa, instead of heterocoral. In case this genus is placed in the heterocoral, it would present a confusion between the Rugosa and the Heterocorallia. Therefore the authors suggest that the family Stylostrotionidae Fedorowski (1991) be placed under the suborder Stauriina of the Rugosa, including Pseudopetraia Soshkina, Palaeophyllum Billings, Stylostrotion Chi, Polygonaria Fan, Sudetiphyllia Fedorowski and Xinglangophyllum gen. nov.</ABSTRACT>

78203 <TITLE>Remarks on the paleobiology of Rugosa.</TITLE>
78204 <SOURCE>Geologos 2: 5-58.</SOURCE>
78205 <ABSTRACT>It is the interpretation of anatomy, behaviour and general physiology of the Rugosa. Variability in the suspected behaviour and general physiology of the Rugosa is inferred from frequently appearing morphotypes in solitary forms. This discussion is preceded by a review of important skeletal and suspect soft features, supported mainly by external characteristics of fossils. Existing skeletal data has led to the proposal of an initial development of two pairs of mesenteries. They are considered to be directive mesenteries by comparison to other Anthozoa. Only the sclerosepta corresponding to these two pairs of mesenteries are considered as protosepta. The cardinal fossula is reconstructed as an important irrigation apparatus, leading to a siphonoglyph above it, but not forming sufficient space to host mesenteries bearing gonads. Clear differences between the skeletal morphology in juvenile and mature parts are discussed in detail using several examples, beginning with reconstruction of earliest skeletogenesis. Secretion of the attachment and first wall of the aseptal cup is postulated as the initiation of the skeletogenesis of the polyp.</ABSTRACT>

78216 <TITLE>Nomenclatural problems of Breviphrentis Stumm 1949 and Contophrentis new genus (Devonian rugose corals).</TITLE>
78217 <SOURCE>Journal of Paleontology 72, 5: 932-934.</SOURCE>
78218 <ABSTRACT>Amplexus invaginatus Stumm, 1937, the type species of Breviphrentis, is from Nevada; my redescription (Oliver, 1993, p. 19-20) was based on the specimens collected by C.W. Memam that were used by Stumm (1937), and Merriam (1940 and 1974) in their descriptions. I concluded that most of the Merriam and Stumm material represented two species, one a siphonophrentid and one from another family (not named); I selected a lectotype from Stumm's (1937) illustrated holotypes and identified it as belonging to the siphonophrentid species (Oliver, 1993, p. 19-20). This had the apparent effect of preserving Breviphrentis as a siphonophrentid and justifying the assignment of the Eastern Americas species to that genus. * Later, Dr. A.E.H. Pedder, Geological Survey of Canada, Calgary, collected a large number of specimens from the type locality and horizon of Amplexus invaginatus in Nevada. During a visit to Pedder's laboratory (April, 1992), I was able to examine the prepared specimens and agreed with his conclusion that the A. invaginatus lectotype belonged to the population represented by his new collection and that it was the non-siphonophrentid. Thus, Breviphrentis sensu stricto is not a siphonophrentid and the Eastern Americas Breviphrentis needs a new name. The purposes of this note are to clarify the status of the Nevada Breviphrentis s.s. (see also Pedder, 1997) and to establish Contophrentis new genus, for the EAR species. 78257 <ABSTRACT>The substrate conditions of mudstone strata formed in ancient epicontinental settings may be determined from taphonomic assemblages of solitary rugose corals. Equal-area plots on the orientations of preserved corals can be used to infer whether subsequent hydrodynamic conditions affected any postmortem reworking of the corals. Mechanically stable positions for curved corals can be determined. Curved corals preserved in mechanically stable positions are interpreted to have been deposited on firm or hard substrates. Curved corals preserved in mechanically unstable positions were probably embedded in soft or soupy substrates.</ABSTRACT>

- 78283 <ABSTRACT>Among representatives of Argutastrea the species quadrigemina (Goldfuss 1826) is characterized by its quadripartite increase, which is a prominent taxonomic feature (Coen-Aubert & Luetete 1990). Within (i.e. "at the cost of) autocorallites four hystero-corallites develop. At the moment accurate investigations of such a peculiar increase were only carried out in Stauria favosa (Koch 1883, Smith & Ryder 1927, Ting 1940). On the basis of numerous series of thin sections and acetate peels of Argutastrea quadrigemina as well as on experimental tests the importance of this budding, but also mutualities and differences to Stauria favosa are discussed.</ABSTRACT>

78320 <TITLE>Skoliophyllum lamellosum and wedekindophyllum marginatum, interpreted as ecological forms of many species of Cystiphyllodes.</TITLE>
78321 <SOURCE>Annales de la Societe geologique de Belgique 93: 183-202.</SOURCE>
78322 <ABSTRACT>Seven species of Cystiphyllodes are described in all of which "lamellosum" and "marginatum" forms are found. Problems concerning "septal cones" and the validity of the so-called "wedekindophyllum" and "Skoliophyllum" are discussed. The possession of "septal cones" is not a specific characteristic, but an internal structure adjusted to the external forms of the corals which are directly influenced by ecological conditions. The so-called "wedekindophyllum" and "Skoliophyllum" are shown to be two special forms of Cystiphyllodes developed in unusual conditions.</ABSTRACT>

(Tétracoralliaire dévonien).</TITLE>
78386 <SOURCE>Bulletin du Museum national d'histoire naturelle, 3e sér.
100, Sciences de la Terre 20: 411-461.</SOURCE>
78387 <ABSTRACT>A revision of Combophyllum osismorum M.E. & H.,
type-species of Combophyllum, is given. This study was carried out on
the original material and on a large collection from the type-locality.
It was possible to state precisely the morphological, structural and
microstructural features of the species. The radiary elements of this
discoid coral are costo-septa of which the growth direction is chiefly
peripheric, distal and proximal. They are composed of trabeculae
arranged in a fan-shaped pattern. The stratigraphical position of the
species is accurately determined (lower part of the Middle Devonian). A
critical revision of the other known species of Combophyllum is
proposed.</ABSTRACT>

78398 <TITLE>The rugose coral genera.</TITLE>
78399 <SOURCE>Elsevier Scientific Publishing Co.; 358 pp., no illustr.</SOURCE>
78400 <ABSTRACT>[review by William A. Oliver jr] This book is in three parts:
an alphabetical listing of generic names with generic and type species
diagnoses (218pp), an identification key to the genera (99pp), and a
list of type species alphabetized by trivial name (11pp). Remaining
pages are occupied by a too brief preface, a reference list and a short
addendum. This is a reference book for the specialist - neither more
nor less. Generic listings are remarkably complete through the 1971
literature. W.J. Sando and I have found only seven missing genera, two
missing spelling variants, and only one misspelled generic name.
Diagnoses range from three to 20 or more lines, and seem to be good.
Apparently they are based on original descriptions and published
revisions; sources are given. Subjective synonyms are separately
diagnosed and not necessarily noted as possible synonyms. This
represents good policy and makes the book more objective and useful. A
questionable procedure is that of proposing 11 new names for junior

homonyms that have been generally accepted as synonyms and not previously renamed. This is consistent with the treatment of other subjective synonyms but will cause trouble if later revisers decide that the genera are not synonyms. Most of the names will find use only in synonymies and other nomenclatural works. In any case, the new names are easily found in the book as all were constructed by adding the prefix *Pro* to the homonym. *New names* (pp 32-33) for specimens originally described as *Gen. I, Sp. I* and *Gen. II, Sp. I* by Kostic-Podgorska (1957) are unnecessary and bad policy. These are new genera and species (with Cotton as author) based on material that the original describer considered inadequate.[part of extensive summary]

 78425 <SOURCE>Jb. Geol. 1972, 4: 439-463.</SOURCE>
 78426 <ABSTRACT>A new morphological term *biform tabularium* is proposed for tabulae arranged in two systems corresponding to two different groups of interseptal loculi (position I and II of Sutherland, 1965). This feature, the variability of which is discussed, occurs in several independent lines of Rugose corals and is known from Upper Ordovician to Upper Permian times. The new genera *Kaljolasma*, *Kabakovitchiella*, *Sutherlandinia*, and *Pedderelasma* are erected for some species with a biform *Tabularium*. The revised family *Cyathaxoniidae* contains Middle Ordovician to Upper Permian genera of five subfamilies (*Petrainae*, *Ditoecholasmatinae*, *Cyathaxoniinae* and two new ones, *Sutherlandiniinae*, and *Lophotichiinae*). *Sutherlandiniinae* and *Ditoecholasmatiinae* are characterized by curious split septa (cardinal, counter, and two counter minor septa). The known definitions of the genera *Barrandeophyllum*, *Haptophyllum*, *Boolelasma*, *Petraia*, and *Lophotichium* have been changed.</ABSTRACT>

78516 <SOURCE>Nauka, Moskva: 123 pp., 85 figs.</SOURCE>
78517 <ABSTRACT>Dans cet important ouvrage l'auteur retrace l'histoire; historique de l'étude des Rugosa, donne ensuite un aperçu de la morphologie du squelette et des méthodes de son étude, ainsi qu'un glossaire des principaux termes. La position systématique des Rugosa au sein des Coelentérés est analysée. Un chapitre est consacré aux tendances évolutives de ce groupe et aux principes de sa classification. L'auteur donne ensuite une revue des principaux genres par familles et groupes taxonomiques supérieurs. Enfin l'auteur traite de l'évolution des Rugosa à travers le Paléozoïque, de leurs conditions de vie, de leur utilisation en stratigraphie et de leur distribution paléogéographique. En dehors de son utilisation très générale, l'intérêt de ce travail réside dans le fait que l'auteur donne son propre point de vue sur tous les principaux problèmes concernant les Rugosa.</ABSTRACT>

78660 <ABSTRACT>This problem is very important for understanding and reconstructing the history of Palaeozoic corals, as well as being very interesting. Really, how could solitary and colonial Rugosa, Tabulata and then Heliolitoidea appear so abruptly at the Early Ordovician / Middle Ordovician boundary? Soft bodied Coelenterata are known from the Late Precambrian and in the Cambrian there were suitable conditions for organisms to form a skeleton and benthic Metazoans took advantage of it, immediately. [first fragment of a paleontological note]</ABSTRACT>

- 78854 <SOURCE>FC#38;P 12, 1: 11.</SOURCE>
- 78855 <ABSTRACT>G. Cotton has now published ; The Rugose Coral Species;. listing some 10 000 species in about 1200 genera, with 2400 references. The primary purpose of this book is to serve as a guide to where the original description of a Rugose Coral species is to be found. * The first section lists alphabetically the species that were originally referred or have subsequently been transferred to each genus, the genera also being listed alphabetically. For each species, the author, date of publication, page number, and horizons are given, and when a species is transferred, the author who first transferred it to the new genus. * In the second section all species are listed alphabetically with the genus to which they were originally referred, and the author and date. This makes it possible to trace the genus to which a species was originally referred even when, as is very frequently the case, only the genus to which it has subsequently been transferred is mentioned. * The third section lists the References, abbreviated in the manner of the World List of Scientific Periodicals, 4th Edition. - 78867 <SOURCE>Journal of Paleontology 56, 5: 1223-1229.</SOURCE>
- 78868 <ABSTRACT>Coiled protocoralla of solitary rugose corals from the Lower Mississippian (Lower Carboniferous) of the United States continental interior suggest two opposing life styles for their early life history. Specimens of Cyathaxonia tantilia have a hollow, coiled protocorallum and represent a coral with a pseudoplanktic brephic stage, as suggested by Sando (1977). Amlexizaphrentis? sp. has planispiral or low spiral protocoralla which are attached to fenestrate bryozoans and consequently had a benthic post-larval habit. These alternative life habits are important for the understanding of rugose coral ontogeny and have significant biostratigraphic implications. [original abstract] </ABSTRACT>

78881 <ABSTRACT>An elevated skeletal structure surrounding an empty axial area occurs in many unrelated taxa within the Rugosa. This structure, commonly termed the aulos, was first differentiated and described by Grabau in 1922. Most terms introduced by that author for individual morphotypes have not been accepted because the taxa he chose to illustrate the typical development do not correspond to his diagnoses. The morphogenetic study on some circumaxial structures in this paper points out differences in their origin, their predicted role in the physiology of the coral polyps. The study shows both the advantages and disadvantages of the use of these circumaxial structures in taxonomy. In addition to the term aulos, which was introduced by Smith in 1928, new terms i.e. circulotheca and columnotheca are here introduced for the circumaxial structures that also are newly proposed names, to allow distinguishing them from true axial structures. 78892 <TITLE>Does similarity in rugosan characters and their functions indicate taxonomic relationship?</TITLE>
78893 <SOURCE>Palaeoworld 19, 3-4: 374-381.</SOURCE>
78894 <ABSTRACT>Functional analysis of changes in shape and arrangement of septa in the genera Zaphrentites, Caninia, and Ufimia allows one to move slightly beyond the usual boundaries of description and to ask why the arrangement in Zaphrentites is permanent, but becomes radial in Caninia and bilateral in Ufimia? This may be explained in terms of changing function and biological role of major septa in the ontogeny.* The creation of open space to accommodate strongly developed mesenteries is proposed as an explanation for the shortening and radial arrangement of axially free septa in mature Caninia, whereas the development of a slit on an oral disc, increasing water flow through the gastro-vascular cavity, is postulated for Ufimia. Both solutions point towards increased effectiveness of feeding and oxygenation, necessary for the growing organism. Such a conclusion negates the simple application of a given arrangement of septa as an indicator of taxonomic relationship. [original abstract]</ABSTRACT>

78905 <TITLE>Remarks on rugose coral taxonomy.</TITLE>

- 78906 <SOURCE>Palaeoworld 19, 3-4: 242-248.</SOURCE>
- 78907 <ABSTRACT>Precise taxonomy is possible only when specimens are thoroughly investigated and checked against well known types. This simple procedure is not always followed and as a result, credible data are often lacking. * Accuracy. To match his interpretation of calice morphology, Schindewolf (1942, pl. 33, fig. 2a-d, text-fig. 89a-d) inaccurately oriented transverse sections of Pentamplexus simulator Schindewolf, 1940. His errors were in part corrected by Weyer and Ilina (1979), but they also misidentified the counter protoseptum. Re-orientation of the original and two new thin sections allows that genus to be transferred to the family Polycoeliidae de Fromentel, 1860. * Manipulation: Schindewolf's (1942) manipulation of the data on Pentaphyllum De Koninck, 1872 and Cryptophyllum Carruthers, 1919 resulted in an incorrect diagnosis, which was followed by many students who introduced 49 species (Ilina, 1984). Despite its name and Schindewolf's (1942) description, the poorly preserved type of Pentaphyllum possesses six, instead of five, dominant septa in its calice. * Lack of attention to detail: Biform morphology in the tabularium is not always recognized and is commonly incorrectly described, despite its importance as a factor in water distribution within the gastro-vascular cavity and its diagnostic value for taxonomy. Failure to recognize that feature can lead to incorrect classification up to the family level.</ABSTRACT>

- 78919 <SOURCE>Abhandlungen und Berichte für Naturkunde 30: 85-145.</SOURCE>
- 78920 <ABSTRACT>The outstanding feature of the Rugosa, their ontogenetic mode of septal insertion, is redefined, based on a new morphogenetic nomenclature of septa. External furrows of the archaeotheca show septal increase either by bifurcation (schizosepta), or by intercalation (intrasepta). The primary phylogenetic radiation in the Late Ordovician comprises the two hitherto accepted orders characterized by schizosepta (metasepta, catasepta), the Stauriida (probably ancestral, with minor septa near antiseptum), and the Cystiphyllida (without antiseptal minor septa); but there exists an additional, completely neglected order Pholidophyllida as a sister group whose major and minor septa are intrasepta (here named addisepta and kalasepta). - 78932 <SOURCE>FC&P 26, 1: 9-16.</SOURCE>

- 78933 <ABSTRACT>[the presented] model is qualified for a reconstruction of ontogeny of rugose corals from the early condition state with only six protosepta. However model is not sufficient to explain earlier phases of ontogeny. I must emphasize that the presented reconstruction is only valid for the generalized representations of the septal insertion mechanisms as described in paleontological textbooks and not for any special group of the tetracorallia. This model might possibly be modified to be valid for some special groups of rugose corals with only small modifications to adjust special situations. Furthermore it may also be applicable to describe and explain the limited capability of rugose corals to build coherent colonies and whole reef constructions as compared to those of madreporarian corals. - 78946 <ABSTRACT>The study of generation and control of shape is an integral part of a constructional approach to organisms. If living beings are understood as organismic constructions, the determination of shape can be explained as being driven by hydraulic, mechanical and energy conducting entities. The recent Anthozoans such as the Actiniaria, Octocorallia, or Scleractinia, can be analyzed in such a manner that it leads to an understanding of their organisation and the physical laws underlying it. * The most important principles that have to be observed for a constructional approach of such organisms are hydrostatic and hydrodynamic physical laws, the principles of coherence, energy transformation and the mechanisms of muscular action, including the antagonistic interaction necessary for the proper functioning of all contractile elements (Gutmann 1991). A proper understanding of these principles leads to the conclusion that no structural transformation in individual development or evolution is arbitrary or accidental (Gutmann & Bonik 1981; Gutmann 1995; Grashoff 1976; Peters & Gutmann 1971; Schmidt-Kittler & Vogel 1991). * The results of a constructional morphology of recent organisms can be applied to analysis of the structural, organizational and functional aspects of fossil organisms. Any anatomical reconstruction of fossil and extinct organisms can only be performed in analogy to that of recent relatives and has to refer to biological and morphological knowledge. In this approach constructional morphology is used as a principle of uniformitarianism (Gudo 1997; Gutmann 1997) in order to reconstruct the lost soft bodies of the fossil rugose corals. 78959 <ABSTRACT>All bauplans of the Anthozoa evolved independently from each other. The ancestor is a so called gallerteroid-coral, an organism which bears a number of polyps, that have developed as closing apparatuses for the openings of the internal canals. When inside these polyps the gastric cavity enlarges, certain numbers of tissue pouches was preserved to hold the polyp in shape. These pouches later formed the mesenteries. The number of the initial developing pouches therefore determined the number of mesenteries and accordingly the bauplan. - 79023 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 153-162.</SOURCE>
- 79024 <ABSTRACT>Detailed blastogenetic investigations using serial acetate peels from stylostrotion sudeticum Fedorowski 1991, a representative of the controversial group Calyxcorallia, revealed that offset formation in the youngest stages is close to some lateral increase in rugose corals. The appearance of heterocoral symmetry in later stages of blastogeny is a feature which would differentiate the blastogeny of the Calyxcorallia from that of the Rugosa. Analysis of the similarities and differences between the blastogeny of S. sudeticum, the Rugosa and the Heterocorallia suggests that it is more appropriate to regard the Calyxcorallia as a group within the Rugosa, rather than grouping them with the Heterocorallia in a separate subclass. However, the possibility cannot be excluded that the Calyxcorallia was a transitional group from the Rugosa to the Heterocorallia, as postulated by Fedorowski (1991).</ABSTRACT>

- 79035 <TITLE>Is the Columnariina (Rugosa) wholly polyphyletic?</TITLE>
- 79036 <SOURCE>FC&P 06, 1: 11-12.</SOURCE>
- 79037 <ABSTRACT>Most workers on the Rugosa must have experienced difficulty in assigning definite and exclusive morphological characters to Suborder Columnariina. In Treatise F (p. F296) a precise diagnosis gives no characters or combination of characters that are not also present in other rugosan suborders. [] The lack of unspecialised ancestors, rarity of solitary corals, dominance of highly evolved compound coralla and the Devonian - Carboniferous stratigraphical

hiatus leads us to believe that the Columnariina are entirely a polyphyletic group. * The suborder appears to create confusion in the genetic taxonomy of the Rugosa as end stages of many lineages have been placed in this group. * We suggest that it would be an advancement to suppress this taxon, but this cannot be done until the specialists in various groups of the Columnariina can reallocate them within the remaining framework of rugosan classification. * We intend to review the British Carboniferous Columnariina and would welcome, through this newsletter, results of research on other groups of Columnariina and suggestions as to their true affinities. 79113 <TITLE>On Classification and Stratigraphical Significance of the Fine
Structure in the Septa of Cystiphyllida.</TITLE>
79114 <SOURCE>Acta Palaeontologica Sinica 25, 1: 75-86.</SOURCE>
79115 <ABSTRACT>The present paper discusses chiefly the morphological
characters, classification and Stratigraphical significance of the fine
structure in the septa of Cystiphyllida. In addition to the discussion
and emendation made of the definitions of the known superfamily,
families and subfamilies, here one new superfamily, one new family and
three new subfamilies have been established. The author considers that
the basic unit of the fine structure in the septa of Cystiphyllida
includes three forms: spinal-tubular skeleton-clasts, lamellar tissue
and lamellar skeleton-clasts. Based on the septal fine structure,
Cystiphyllida can be divided into two superfamilies: Cystiphyllidae and
Zonechyllicae. The septa of Cystiphyllidae are made up of
spinal-tubular skeleton-clasts and lamellar tissue; this superfamily
chiefly appeared in Silurian. The septa of Zonechyllicae are only
composed of lamellar skeleton-clasts; most of members of the
superfamily occurred in Devonian.</ABSTRACT>

79139 <TITLE>Skeletal structures and classification of the Order Cystiphyllida (Rugosa).</TITLE>
79140 <SOURCE>Geoscience 1, 1: 3-14 [in Chinese, with English summary].</SOURCE>
79141 <ABSTRACT>SEM study on the microskeletal structures of more than 10 cystiphyllid genera has revealed that lamellar skeleton with fundamental unit calcite flakes 15-35 μm in diameter and 1.5-2.5 μm in thickness is in all cases dominant, while fibrous skeleton is mostly represented by primitive types, by irregular granules some 2-3 μm in diameter and brachycolumns 2-3 μm in diameter and 5-10 μm in length. These two kinds of elements combine in various ways to form 4 types of septal spines or trabeculae. They are (1) holacanth, tube-like and entirely lined with lamellar flakes; (2) single rhabdacanth with axial granules enveloped by peripheral flakes; (3) composite rhabdacanth comprising axial row of clusters of rhabdacanths embedded in interstitial and enveloping lamellar flakes, and (4) monacanth composed of parallel to subradial brachycolumns or short needles. They are exemplified respectively by Protocystiphyllum, Holmophyllum, Gyalophylloides and Tryplasma. Based on these microstructures and megastructures we have recognized 50 genera of cystiphyllid corals grouped into 8 families. They are: Primitophyllidae, Palaeocyclidae, Tryplasmataidae, Cystiphyllidae, Mucophyllidae, Holmophyllidae, Goniophyllidae and ketophyllidae. Diagnoses of the families are given and briefly discussed, and genera included in the families are named. Microstructures of some important genera are indicated in the caption of plates. Stratigraphical and geographical distribution in China and in the world are given in Table 1. Possible evolutionary and taxonomic relations are shown in the figures. It is deemed that the two earliest appeared families, Primitophyllidae and Mucophyllidae, came from different descent. Palaeocyclidae and Tryplasmataidae were probably derived separately from Primitophyllidae. A third branch is Cystiphyllidae, which underwent radiating evolution to form the 4 families in the beginning of the Silurian and became the major constituents of the group until the end of Early Devonian, when most of the cystiphyllids died out. Ketophyllidae may however represent another separate lineage directly from Primitophyllidae.</ABSTRACT>

79167 <ABSTRACT>Dividocorallia Fedorowski 1991, the recently distinguished subclass of extinct Devonian and Carboniferous Anthozoa, comprises two orders: Heterocorallia Schindewolf 1941 and Calyxcorallia Fedorowski 1991. The arrangement and development of septa are fundamental characters common for the subclass. It has been postulated that only a single septum appeared at the very beginning of septogenesis in both orders. This common character of orders points on the Rugosa as the ancestral group of the Dividocorallia. Presence (Calyxcorallia) or absence (Heterocorallia) of calices is the basic distinguishing character of the order-level. It can be traced back to the Lower Devonian, when the oldest representatives of both orders occur. Pseudopetraia Soshkina 1951 represents Calyxcorallia whereas Tetrephyllia Yoh et al. 1984 is the oldest known heterocoral. Symmetrical (Tetrephyllina Fedorowski 1991) versus asymmetrical (Heterocorallia) arrangement of septa allows to distinguish suborders within the order Heterocorallia, whereas morphogenesis and microstructure of the external wall are the basic diagnostic characters of families of that order. The order Calyxcorallia comprises families that are distinguishable by the form of growth: solitary versus colonial. Majority of genera included in Calyxcorallia were formerly described as rugose corals.</ABSTRACT>

79321 <TITLE>On the taxonomy and evolution of the family Stauriidae (Rugose corals).</TITLE>
79322 <SOURCE>Acta Palaeontologica Sinica 22, 4: 389-397.</SOURCE>
79323 <ABSTRACT>This paper deals with the taxonomy and evolution of the family Stauriidae. The diagnostic features of the Stauriidae are emended. Besides the shape of corallum, the differentiation of tabulae and the two rows of dissepiments, the axial increase shows a quadripartite gemmation in the calyx with four major septa (Teilungssepten) becoming longer and stronger, and crossed at the center. However, the gemmation may also be tripartite, pentapartite or rarely hexapartite. This family includes five genera and two subgenera: Ceriaster, Ceriaster (Eostauria) subgen.nov., Ceriaster (Ceriaster), Paraceriaster (He Yuanxiang 1980), Stauria, Parastauria and Cyatostauria gen.nov.</ABSTRACT>

- 79375 <ABSTRACT>Scleractinian and rugose corals demonstrate a broad environmental distribution; both clades have a relatively high diversity of representatives which live(d) at great depths. In order to determine the nature of diversification of these deep-water forms the paleoenvironments of the earliest Rugosa and representatives of extant deep-water scleractinian families were determined. Environmental patterns of the subsequent diversification of the Rugosa and scleractinian suborder Caryophyllina were also documented. The earliest reported Rugosa is Lambeophyllum from the Chazyan Crown Point Limestone (Vermont, U.S.A.) which is interpreted to have been deposited in a nearshore setting. Within five million years of their initial appearance the rugosans expanded, at relatively low diversities, offshore to the slope and deep-basin. Nearly all representatives of

families of extant scleractinians now living in deep-water (>200m;) also first occur in an onshore environment. The caryophylliids, the most specious deep-water coral clade, first appeared in the Toarcian and soon after expanded across the shelf. Thus, both rugose and scleractinian corals expand offshore at relatively low diversities early in their histories. Throughout most of the Mesozoic high diversities of caryophylliids occur in shelfal settings. In the Tertiary high diversity patterns in the outer shelf and slope are established.</ABSTRACT>

79386 <TITLE>Rugosa and Scleractinia - a commentary on some methods of phylogenetic reconstructions.</TITLE>

79387 <SOURCE>Acta Palaeontologica Polonica 42, 3: 446-456.</SOURCE>

79388 <ABSTRACT>A critical review of two papers: (1) Dzik J.: Early metazoan evolution and meaning of its fossil record. Evolutionary Biology, 27, 1993 and (2) Stolarski J.: Gardineria - a scleractinian living fossil. Acta Palaeont. Polonica, 41, 1997. An approach of Dzik to the reconstruction of phylogeny and roots of Rugosa was questioned. The inadequately known morphology and ontogeny of Cothonion, as well as differences in the microstructure of the external wall and increase in septa between that Middle Cambrian genus and the Rugosa, established by Jell & Jell (1976) eliminate it from potential ancestors of the Rugosa. Its similarity to the Devonian genus Calceola is superficial and those two cannot be compared as relatives. The operculate taxa postulated by Dzik (1993) to be ancestors for all the Rugosa appeared to being when all basic morphotypes of non-operculate Rugosa were already flourishing. Thus, all phylogenetic conclusions by Dzik (1993) were rejected. Stolarski (1996) in his study on the Recent Gardineria attempted to prove a thesis of the rugosan origin of Scleractinia. The long known similarity in morphology and microstructure of those two subclasses (or Orders) of the Anthozoa, as well as equally well known differences between them, were briefly discussed in the critique to show parallelism in the development rather than true relationships of those taxa. An absence of the Rugosa from all latest Permian strata, despite proper ecological conditions some of the offer, speaks more strongly against a direct relationship of those two large taxa than an absence of Scleractinia from equally proper conditions existing in Early Triassic.</ABSTRACT>

79399 <TITLE>Analogie entre la structure du squelette chez les Coraux Combophyllum (Dévonien) et Chomatoseris (Jurassique), en relation avec leur mode de vie.</TITLE>

79400 <SOURCE>C. R. Acad. Sc. Paris ser. D, 273: 49-50.</SOURCE>

79401 <ABSTRACT>Le développement du squelette vers le bas en ménageant un espace à l'intérieur du Madréporaire, a été signalé chez

Chomatoseris. Le même type de structure vient d'être trouvé chez Combophyllum. Cette formule structurale est liée à un mode de vie bien déterminé: état libre du Madréporaire sur un fond instable et faculté de s'y déplacer. Une telle similitude entre Madréporaires très éloignés dans le temps et dans la systématique, témoigne d'un assujettissement aux lois du milieu.

 79439 <SOURCE>Paläontologische Zeitschrift 59, 3/4: 201-210.</SOURCE>
 79440 <ABSTRACT>The study of the morphology of the rugose corals and the acceptance of a solitary sexual polyp, as the stem form of the Anthozoa (B. WERNER) lead to the conclusion that the stem form of the rugose corals was a solitary sessile polyp without a base disc and with four or more pairs of mesenteries from which two were directive pairs. Therefore it seems correct to supply the name Rugosa by Tetracorallia Haeckel 1866. The evolution of the Auloporida from such a stem form follows another trend, which is characterised by the development of colonies. It seems possible, that this trend was attended with the reduction and the loss of the four mesenteries of the hypothetical stem form. Therefore it is not sure, that the Auloporida belong to the Anthozoa.</ABSTRACT>

79505 <ABSTRACT>Dans les sediments du Maestrichtien en Bulgarie du Sud-Ouest on a ramasse deux polypiers, dont la structure montre quelques differences dans la morphologie des polypierites. Chaque colonie possede des polypierites qui caracterisent deux genres - Columnocaenia ALLOITEAU et Placocaenia d'ORBIGNY. La partie predominante des calices possede la structure du genre Columnocaenia. On observe aussi des calices avec la structure simultanement des genres Columnocaenia et Placocaenia. La presence des calices indiquant les particularites simultanement des deux genres demontre la relation phylogenetique entre les genres Placocaenia et Columnocaenia.</ABSTRACT>

79529 <TITLE>Nanostructure of biogenic versus abiogenic calcium carbonate crystals.</TITLE>
79530 <SOURCE>Acta Palaeontologica Polonica 50, 4: 847-865. <http://www.app.pan.pl/article/item/app50-847.html></SOURCE>
79531 <ABSTRACT>The mineral phase of the aragonite skeletal fibers of extant scleractinians (Favia, Goniastrea) examined with Atomic Force Microscope (AFM) consists entirely of grains ca. 50-100 nm in diameter separated from each other by spaces of a few nanometers. A similar pattern of nanograin arrangement was observed in basal calcite skeleton of extant calcareous sponges (Petrobiona) and aragonitic extant stylasterid coralla (Adelopora). Aragonite fibers of the fossil scleractinians: Neogene Paracyathus (Korytnica, Poland), Cretaceous Rennensismilia (Gosau, Austria), Trochocyathus (Black Hills, South Dakota, USA), Jurassic Isastraea (Ostromice, Poland), and unidentified

Triassic tropiastreaeid (Alpe di Specie, Italy) are also nanogranular, though boundaries between individual grains occasionally are not well resolved. On the other hand, in diagenetically altered coralla (fibrous skeleton beside aragonite bears distinct calcite signals) of the Triassic corals from Alakir Cay, Turkey (Pachysolenia), a typical nanogranular pattern is not recognizable. Also aragonite crystals produced synthetically in sterile environment did not exhibit a nanogranular pattern. Unexpectedly, nanograins were recognized in some crystals of sparry calcite regarded as abiotically precipitated. Our findings support the idea that nanogranular organization of calcium carbonate fibers is not, per se, evidence of their biogenic versus abiogenic origin or their aragonitic versus calcitic composition but rather, a feature of CaCO₃ formed in an aqueous solution in the presence of organic molecules that control nanograin formation. Consistent orientation of crystallographic axes of polycrystalline skeletal fibers in extant or fossil coralla, suggests that nanograins are monocrystalline and crystallographically ordered (at least after deposition). A distinctly granular versus an unresolvable pattern of nano-organization of CaCO₃ fibers seems to correspond, respectively, to an original versus a diagenetically depleted amount of organic matter bounding a mineral phase; this is consistent with qualitative and quantitative analyses of organic matter content in extant and fossil skeletons</ABSTRACT>

79542 <TITLE>The evolution of modern corals and their early history.</TITLE>

79543 <SOURCE>Earth-Science Reviews 60, 3-4: 195-225.</SOURCE>

79544 <ABSTRACT>Scleractinians are a group of calcified anthozoan corals, many of which populate shallow-water tropical to subtropical reefs. Most of these corals calcify rapidly and their success on reefs is related to a symbiotic association with zooxanthellae. These one-celled algal symbionts live in the endodermal tissues of their coral host and are thought responsible for promoting rapid calcification. The evolutionary significance of this symbiosis and the implications it holds for explaining the success of corals is of paramount importance. Scleractinia stands out as one of the few orders of calcified metazoans that arose in Triassic time, long after a greater proliferation of calcified metazoan orders in the Paleozoic. The origin of this coral group, so important in reefs of today, has remained an unsolved problem in paleontology. The idea that Scleractinia evolved from older Paleozoic rugose corals that somehow survived the Permian mass extinction persists among some schools of thought. Paleozoic scleractiniamorphs also have been presented as possible ancestors. The paleontological record shows the first appearance of fossils currently classified within the order Scleractinia to be in the Middle Triassic. These early Scleractinia provide a picture of unexpectedly robust taxonomic diversity and high colony integration. Results from molecular biology support a polyphyletic evolution for living Scleractinia and the molecular clock, calibrated against the fossil record, suggests that two major groups of ancestors could extend back to late Paleozoic time. 79555 <TITLE>Antiquity of the scleractinian-sipunculan symbiosis.</TITLE>
79556 <SOURCE>Acta Palaeontologica Polonica 46, 3: 309-330.</SOURCE>
79557 <ABSTRACT>Extant corals symbiotic with sipunculans, i.e., the caryophylliid Heterocyathus and the dendrophylliid Heteropsammia, develop corallum modifications (in comparison with ordinary representatives of these families) that seem to meet the needs of the coral's worm partner. We distinguish two types of corallum modifications, designated the monoporous and the polyporous types. In the adult monoporous type, the shell inhabited by the sipunculan is usually overgrown only in part by the coral base. There are two orifices: the main one and a smaller pore in the upper part of the corallum. In the polyporous type the shell inhabited by the sipunculan is entirely overgrown and the coral produces a spiralled sipunculan housing. In addition to the main orifice there are several pores in the lower part of the corallum. Heterocyathus priscus sp. n. from the Early Cretaceous (Albian) of France is the oldest example of symbiosis, in which the monoporous-type corallum was modified in the same way as in extant monoporous Heterocyathus. We speculate that the monoporous type was ancestral, as only this type is known to occur among Cretaceous corals. Morphological similarities between Heteropsammia and certain species of Heterocyathus, such as the Pourtalés plan of septal arrangement and skeleton porosity, may point to a close phylogenetic relationship.</ABSTRACT>

79568 <TITLE>Image processing as a tool for reconstructing the skeletal early evolution for branching scleractinian corals (Acropora danai and Pocillopora verrucosa): preliminary results.</TITLE>
79569 <SOURCE>Géologie Méditerranéenne 27, 3-4: 107-117.</SOURCE>
79570 <ABSTRACT>For the first time, the early evolution of branching corals skeleton (Acropora danai and Pocillopora verrucosa) has been depicted using image processing technique. Several parameters have been measured on digitized pictures of coral sections in order to characterize the geometry, and its evolution with increasing age of corallum, of intraskeletal cavities (fenestral pores). It has been possible to describe precisely the mesostructure of corals and together with the study of the microstructure, it has also been possible to link evolution of the different measured geometrical parameters to biotic or to abiotic (diagenetic) precipitation of aragonite. A biotic or abiotic process both lead to a strengthening of basal parts of branches, it is very difficult to identify the two types of aragonite. For this purpose, it appears from this study that the hydraulic radius (surface/perimeter ratio) may be one of the most useful parameters to measure. The recognition of early marine diagenetic aragonite is only a first step towards its quantification which will only be completed by the use and the development of image processing technique.</ABSTRACT>

79581 <TITLE>Towards a new synthesis of evolutionary relationships and classification of Scleractinia.</TITLE>
79582 <SOURCE>Journal of Paleontology 75, 6: 1090-1108.</SOURCE>
79583 <ABSTRACT>The focus of this paper is to provide an overview of historical and modern accounts of scleractinian evolutionary relationships and classification. Scleractinian evolutionary relationships proposed in the 19th and beginning of the 20th centuries were based mainly on skeletal data. More in-depth observations of the coral skeleton showed that the gross-morphology could be highly confusing. Profound differences in microstructural and microarchitectural characters of e.g., Mesozoic microsolenine, pachythealine, stylophylline, and rhipidogyrine corals compared with nominotypic representatives of higher-rank units in which they were classified suggest their separate (?subordinal) taxonomic status. Recent application of molecular techniques resulted in hypotheses of evolutionary relationships that differed from traditional ones. The emergence of new and promising research methods such as high-resolution morphometrics, analysis of biochemical skeletal data, and refined microstructural observations may still increase resolution of the skeletal approach. Achieving a more reliable and comprehensive scheme of evolutionary relationships and classification framework for the Scleractinia will require close co-operation between coral biologists, ecologists, geologists, geochemists, and paleontologists.

79595 <SOURCE>Internat. Symposium on Concepts and Methods in Palaeontology: 163-172; Barcelona.</SOURCE>
79596 <ABSTRACT>The main characters between Palaeozoic and post-Palaeozoic Madreporaria are outlined. Skeletal mineralogy seems to be the more important differentiation. It began in the Permo-Triassic boundary. During this period, numerous faunas were also changing. Factors leading calcite and aragonite secretion in marine organisms are considered. The necessity to study experimentally the carbonate secretion in Hexacorallia is ascertained. The results may help to give an interpretation to the Permo-Triassic changes. [original summary]

79634 <SOURCE>Journal of Structural Biology 161, 1: 74-82.PMID 17998166</SOURCE>
79635 <ABSTRACT>Microscopic (AFM and FESEM) observations show that scleractinian coral biomineral fibers in extant Desmophyllum and Favia, and fossil Jurassic Isastrea are composed of nanocrystalline grains of about 30-100 nm in size. In contrast to these findings, SR diffraction data on the same coral materials exhibit narrow Bragg peaks suggesting much larger crystallite size. These seemingly contradicting results of microscopic and diffraction studies are reconciled within a new, minute-scale model of scleractinian biomineral fibers. In this model, nanocrystalline aragonite units are interconnected by mineral bridges and form aggregates usually larger than 200 nm. Most likely, the size of the aggregates is resulting from physiological biomineralization cycles that control cellular secretion of ions and biopolymeric species. Intercalation of biopolymers into crystal lattice may influence consistently several structural parameters of the scleractinian coral bio-aragonite in all studied samples: (i) the lattice parameters and internal strains of the bio-aragonite are larger than in mineral aragonite, (ii) lattice parameter elongations and internal strains reveal directional anisotropy with respect to crystallographic axes.</ABSTRACT>

79646 <TITLE>Mise au point sur les scleractiniaires comme indicateurs de profondeur (Cnidaria: Anthozoa). [review of the scleractinians as depth indicators; in French, with English summary] </TITLE>
79647 <SOURCE>Geol. Mediterraneenne 15, 1: 27-47.</SOURCE>
79648 <ABSTRACT>Before considering the use of fossil scleractinians as depth indicators, their living counterparts are presented in their morphological and ecological diversity. Jointly, the main environmental factors conditioning their geographical and depth distribution are pointed out. Intraspecific variation depending on environmental factors makes taxonomy of the group more complicate. Taxonomy is yet far from being satisfactory for many taxa, particularly to some areas. The terms hermatypic - ahermatypic as currently used by biologists and geologists, are not without ambiguities due to the original definition (Wells 1933); they are discussed together with complementary terms, which had been introduced in order to remedy to that ambiguity. In case of precise taxonomy and well recorded ecology, reference to living scleractinians permits extrapolation of paleoenvironments corresponding to fossil assemblages. It is important to distinguish between shallow water coral reefs of the tropical type and scleractinian constructions in deep water, characters useful for this distinction are indicated. But the present contribution more specifically aims at demonstrating the usefulness of non-reefal scleractinians as indicators of depth (and temperature). According to Wells (1967), the depth (and temperature) interval common to the taxa present in a fossil assemblage can be estimated by reference to identical or related living forms. This provides an approximation for the paleoenvironment under analysis. It is essential to detect an eventual mixture of faunas issued from significantly different depth levels in order to avoid the pitfall of averaging incomparable data. At least for assemblages of a rather young geological past, extrapolations can be remarkably precise (examples of Pleistocene faunas from the Mediterranean). However, the more remote in age the assemblages are, the less precise will be the results because more and more taxons in common with the Recent drop out. Analysis of morphofunctional adaptations, detached from any taxonomic basis, will provide, at best, only general information on the type of the environment (deep or shallow) and of the substrate (soft or hard, stable or unstable).</ABSTRACT>

79698 <TITLE>A molecular perspective on the evolution of scleractinian corals.
</TITLE>
79699 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.):
Paleobiology and Biology of Corals]: 39-57.</SOURCE>
79700 <ABSTRACT>The evolutionary history of scleractinian corals, based on
morphological taxonomy and inferences from the fossil record, has been
poorly understood. Molecular techniques developed over the past ten
years are now being used to gain a new perspective on scleractinian
phylogeny. DNA sequences, mitochondrial genome structure, and
morphological characters support a basal position for the Anthozoa in
the phylum Cnidaria. Mitochondrial and nuclear DNA sequences suggest a
relatively derived position of the order Scleractinia within the class
Anthozoa. Mitochondrial and nuclear DNA sequences have provided a new
hypothesis for evolution within the Scleractinia that is different from
hypotheses based on morphological characters of extant and fossil taxa.
Groupings within the two major lineages defined by molecular data do
not correspond to morphological suborder groupings although groupings
of genera within families do correspond to traditional taxonomy. This
new molecular hypothesis suggests that the Scleractinia are represented
by two major lineages that diverged from each other before the
appearance of the scleractinian skeleton in the fossil record. This

divergence time supports the hypotheses that the Scleractinia are not related to the Rugosa of the Paleozoic and that the scleractinian skeleton has evolved more than once. These two major lineages may represent two architectural strategies within the Scleractinia that have led to their great morphological diversity.</ABSTRACT>

79712 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.): Paleobiology and Biology of Corals]: 187-206.</SOURCE>
79713 <ABSTRACT>Skeleton microstructure of Recent scleractinians proves to be a valuable suprageneric taxonomical criterion, and the same has been stated with respect to Mesozoic corals where skeletal preservation is aragonite. In paleontological practice, septal microstructure is decisive in discrimination of taxa among homeomorphic genera of different families. Similarities of microstructural features of some Recent and fossil corals encompass the genera in common taxa of higher ranks and allow for reconstruction of their presumed phylogeny.</ABSTRACT>

79738 <SOURCE>Acta Palaeontologica Polonica 36, 2: 239.</SOURCE>
79739 <ABSTRACT>A name Cyclophyllia Roniewicz 1989 (type-species Thecosmilia

cyclica Schaefer et Senowbari-Daryan 1978, Triassic) is to be replaced by Cycliphyllia nom.n. and the orthography of the family-name Cyclophylliidae Roniewicz 1989 changed into Cycliphylliidae nom.n. The just replaced generic name is a junior homonym of Cyclophyllia Milne-Edwards & Haime 1848 (type-species Cyclolites cristata Lamarck 1801, Cretaceous). It was a List of Generic Names by Wells 1986 which for the second time helped me in correction of the regrettable errors.</ABSTRACT>

79791 <ABSTRACT>Triassic Scleractinia were originally differentiated into four microstructurally defined groups (pachythechal, thick-trabecular, minitrabecular and fascicular), which were represented by at least 7 of more or less independent phyletic stems of familial or suprafamilial rank that varied in their evolutionary plasticity. The Recent coral fauna seems to be composed of descendants of only three of them. Diastrophic events resulted in changes of the environment, stimulated coral evolution and re-organization of coral faunas. In the Mesozoic, diastrophism controlled the development of an offshore platform variety of the shallow-water coral faunas, while in the Cenozoic it controlled the development of its littoral variety.</ABSTRACT>

79815 <TITLE>Intra-colony variability of calice characteristics in Recent Porites lutea Milne-Edwards & Haime 1816: implications for fossil identification.</TITLE>
79816 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 305-316.</SOURCE>
79817 <ABSTRACT>Patterns of morphological variation in calice characteristics were investigated within a single colony of Porites lutea Milne-Edwards & Haime 1816 from the Northern Red Sea. Hierarchical cluster analysis and canonical discriminance analysis revealed four groups of calice morphs to occur within this colony. The most clearly discriminating variables were calice size and thickness of thecae,

besides the thickness and length of septa and the development of pali. The development and degree of fusion within the ventral triplet as well as columella diameter had the lowest correlation with the discriminant functions. The most stable characters were the pattern of fusion within the ventral triplet and the development of the columella. Corallites from the upper face of the colony (vertical growth direction) were different from corallites on the lateral face of the colony (horizontal growth direction). For the identification of fossil Porites it is necessary a) to obtain calices from several regions of the specimen in order to give a sample of corallite variability, b) It is necessary to fully sample the pattern of septal fusion in the ventral triplet, as this is a stable character at a colony level.</ABSTRACT>

79828 <TITLE>Biomineralization features in scleractinian coral skeletons: source of new taxonomic criteria.</TITLE>
79829 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 129-141.</SOURCE>
79830 <ABSTRACT>In Scleractinian coral taxonomy, major phylogenetic lineages are based on hypothesized relationships among septal microstructures, and various indications suggest that the widely used scheme proposed by Wells (1956) have to be reexamined. The last decade of studies of biomineralization process have demonstrated the leading role that specific macromolecules play during the growth of calcareous biocrystals. These results make possible a new microstructural approach, based on organo-mineral relationships examined at the micronic scale. In addition, biochemical informations obtained from extracted and purified macromolecules can be studied by multivariate analysis, resulting in diagrams showing the biochemical distances between species that can be compared to RNA / DNA based data. Thus, biochemically-based data provide us with evolutionary-related criteria by which phylogenetic distances can be assessed between the skeletal structures.</ABSTRACT>

79841 <TITLE>Adelocoenia versus Pseudocoenia - some rectifications.</TITLE>
79842 <SOURCE>FC&P 27,1: 29-32.</SOURCE>
79843 <ABSTRACT>Colonial corals with small round calices, rudimentary septa and no columella of the suborder Stylinida (Scleractinia) are abundant in the Upper Jurassic and Cretaceous (Berriasian-Cenomanian). Several very similar genera are known. Based on Alloiteau (1948) and the type material available at that time, I tried to clarify this problem (Loser 1994). I proposed the use of Adelocoenia, instead of Pseudocoenia and Cyathophora. This proposal was repeatedly discussed in this newsletter (Baron-Szabo & Bertling 1995, 1996), as well as in Baron-Szabo & Steuber (1996) and Baron-Szabo (1997) but not accepted. * Generally, the IRZN [International Code of Zoological Nomenclature] force[s] us to

consider genera and species in relation to their type species and type specimens. Our personal opinion on a certain taxon may be interesting but has no influence on its taxonomical status. This short note provides some information on type species and types which were ignored in my own work and in the previously mentioned discussions as well.

79854 <TITLE>Evolutionary trends in the epithecate scleractinian corals.

</TITLE>

79855 <SOURCE>Acta Palaeontologica Polonica 44, 2: 131-166.</SOURCE>

79856 <ABSTRACT>Adult stages of wall ontogeny of fossil and Recent scleractinians show that epitheca was the prevailing type of wall in Triassic and Jurassic corals. Since the Late Cretaceous the frequency of epithecal walls during adult stages has decreased. In the ontology of Recent epithecate corals, epitheca either persists from the protocorallite to the adult stage, or is replaced in post-initial stages by trabecular walls that are often accompanied by extra-calicular skeletal elements. The former condition means that the polyp initially lacks the edge zone, the latter condition means that the edge zone develops later in coral ontogeny. Five principal patterns in wall ontogeny of fossil and Recent Scleractinia are distinguished and provide the framework for discrimination of the four main stages (grades) of evolutionary development of the edge-zone. The trend of increasing the edge-zone and reduction of the epitheca is particularly well represented in the history of caryophylline corals. We suggest that the development of the edge-zone is an evolutionary response to changing environment, mainly to increasing bioerosion in the Mesozoic shallow-water environments. A glossary is given of microstructural and skeletal terms used in this paper.</ABSTRACT>

79867 <TITLE>Essai d'établissement d'une banque de données permettant d'analyser les variations des caractères morphologiques des Scleractiniaires en relation avec leur environnement.</TITLE>

79868 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 2]: 411-417.</SOURCE>

79869 <ABSTRACT>Some 480 characteristics concerning the sedimentological environment of Scleractinia, about 30 ones concerning their ecology and almost 420 other ones dealing with their morphology have been inventorized and arranged on an hierarchical system, with view to introduce them in a data bank and to process them by a computer, and to compare the anatomical characteristics of the genera and species with those of their environmental changes. Entrance of these whole characteristics is done on a 20 Mo hard disk. Four chained data bases will be programmed to compare these numerous data: a data base for

generalities (name of genus, species, geographical and stratigraphical localization, references, etc.), a data base for sedimentological characteristics, a data base for ecology and a data base for morphological features. As the data bases are chained, it will be possible to put in very varied questions such as: what is the geographical or ecological distribution of one genus, of one species? - what species are present in a given environment? - what anatomic features are specific for a given environment? or - what ecological conditions are required for a given anatomic feature? - etc. </ABSTRACT>

79919 <TITLE>Calcium binding substance in the hermatypic coral, *Acropora hebes* (Dana).</TITLE>
79920 <SOURCE>Origin, Evolution, and Modern Aspects of Biomineralization in Plants and Animals [R.E. Crick (ed.)]: 167-173; Plenum Press, New York.</SOURCE>
79921 <ABSTRACT>A characteristic of skeleton formation in the hermatypic coral *Acropora hebes* has been investigated, with special reference to the calcium-binding substance assay. The skeletal soluble organic matrix such as protein and carbohydrate did not bind calcium ions in the Sephadex G-75 chromatography. On the other hand, the insoluble organic matrix of the skeleton showed the calcium-binding ability, which was reduced by treatment with organic solvent. Presumably, the calcium-binding substances in the skeletal insoluble matrix are firmly attached to the calcium carbonate crystals and will not be extracted by the aqueous or organic extracting solutions. The major component of the calcium-binding substances in the skeleton is phospholipid, but not the other lipids such as neutral lipid or glycolipid. A high-performance TLC revealed that the skeletal calcium-binding phospholipids consisted of acidic phosphatidylserine.</ABSTRACT>

79971 <TITLE>Notes on Aragonite in Scleractinian Coral.</TITLE>
79972 <SOURCE>Bulletin Tokyo College of Domestic Science 14: 141-145.</SOURCE>
79973 <ABSTRACT>The writer conducted some experiments on the alteration of aragonite in recent and fossil scleractinian coral under various temperatures. He used Pavona frondifera, Acropora sp., Montipora hispida, Pectinia lactuca, Echinophyllia aspera and Acropora leptocyathus as recent specimens and Favia speciosa, Premocyathus compresus, Porites sp. and Goniopora sp. as fossil specimens. The materials of the specimens were experimented with DTA under normal pressure, and crystal structures of some of them were investigated by means of X-rays. As a result of the experiments, the following can be said: (1) Recent and Quaternary scleractinian corals are aragonite in all of various species; (2) the aragonite in coral was inverted to calcite lower temperature (about 310°-320°C) than that of inorganic aragonite; (3) the DTA curves of the samples of recent and Alluvium fossil coral showed exothermic peak in the neighborhood of 430°C. It is supposed that some organic materials exist in the aragonitic materials.

80088 <TITLE>Ontogeny of 'epithecal' and septal structures in scleractinian corals.</TITLE>
80089 <SOURCE>Lethaia 13, 4: 321-326.</SOURCE>
80090 <ABSTRACT>The ontogenetic development of a solitary scleractinian coral, Flabellum distinctum Edwards & Haime, has been studied in serial thin section, with special attention being paid to epithecal nature in relation to septal growth. The term 'epitheca' has been confusingly used for two different skeletal structures: epitheca (sensu stricto) and marginotheca. The latter is here newly proposed, 'epitheca' is defined as a calcareous investment developed on the outside of other skeletal structures of a corallite. It can be distinguished from the marginotheca in section by lacking a dark line (calcification centre) and by being unrelated to the formation of septa, 'marginotheca' defines the outer margin of the main skeletal structures of a corallite. It has a dark line which functionally coincides with that of the eutheca. It is of primary origin, preceding formation of septa and provides the origin of the septa. The marginotheca is one of the more important and fundamental skeletal structures for coral classification.</ABSTRACT>

80103 <ABSTRACT>Endlich ist die seit langem angekuendigte und von vielen Fachkollegen erwartete Neubearbeitung der rezenten kubanischen Korallenfauna durch Dr. Vassil N. Zlatarski erschienen. Als gemeinsamer Herausgeber des umfangreichen und stattlichen werkes zeichnen das Geologische Institut der bulgarischen Akademie der Wissenschaften und das Institut fuer Ozeanologie der Akademie der Wissenschaften Kubas. Erschienen ist die vorliegende Fassung beim Verlag der bulgarischen Akademie der Wissenschaften in russischer Sprache. Eine franzoesischsprachige und eine englischsprachige Ausgabe sind in Vorbereitung. […] handelt es sich um ein gutes und anregendes Buch, das Zeugnis ablegt von der umfangreichen, sich ueber mehrere Jahre erstreckenden Arbeit des Autors an den kubanischen Korallen. Hierzu ist dem Autor aufrichtig zu gratulieren. Spaetestens wenn die einem breiteren Publikum leichter zugaengliche franzoesischsprachige und die englischsprachige Ausgabe erhaeltlich sein wird, duerfte es zu einem vielzitierten Nachschlagewerk fuer karibische Korallen werden. Dann wird wahrscheinlich auch die Diskussion um die vorgeschlagenen taxonomischen Aenderungen erst die richtige Belebung erfahren. [initial and final fragments of extensive review]</ABSTRACT>

80128 <SOURCE>FC&P 02, 2: 34-55.</SOURCE>
80129 <ABSTRACT>The large amount of publications on Scleractinian fossils written in many different languages during last years clearly show how necessary is a lexicon in which every specialist could find the equivalence between the terms used. * In the present article, we have voluntarily not quoted the terms concerning living tissues, except when necessary for the understanding of fossil forms. * A succinct list of the main references in every language, on which this terminology was established, is given in supplement. * We are fully aware of the imperfections of this first attempt, it would be necessarily [to have it] completed and improved under the responsibility of an international commission. * Nevertheless, we would like to dedicate it to the late Dr

- Alloiteau who had so intensively contributed to the establishment of Scleractinian nomenclature. * This glossary, as we hope, is the witness of our wishes for close collaboration between all specialists of Cnidarian fossils. [introduction to the glossary] </ABSTRACT>

80141 <SOURCE>FC&P 04, 1: 14-15.</SOURCE>
80142 <ABSTRACT>It occurs to me that it is desirable to establish clearly our relationship with any group of animals, vertebrate or invertebrate, that we choose to study. Are we to be master, servant or partner? For example, our relationship with a member of the cat family is likely to be that of an inferior; with the dog, Man has traditionally been the master; with most reptiles, Man has maintained a precarious and uneasy relationship. When we come to the invertebrates, however, the position is not so simple and clear-cut. Some readers may think it merely frivolous to suggest that Man could have any kind of a relationship with the coral polyps. But I believe it is not only amusing but useful to look at the Scleractinia to find some analogies with human organisation and behaviour. [] The main lesson which Man could learn from the corals is the importance of maintaining a balance between the individual and the group (colony) and the environment. This is, after all, essential to the success of most species. [first and last fragments of a short essay] </ABSTRACT>

80166 <TITLE>The converging results of microstructural analysis and molecular phylogeny: Consequence for the overall evolutionary scheme of post-Paleozoic corals and the concept of Scleractinia.</TITLE>
80167 <SOURCE>Palaeoworld 19, 3-4: 357-367.</SOURCE>
80168 <ABSTRACT>During the last three decades, a series of paleontological and biological results have brought considerable changes to the

Long-standing question of a possible relationship between the Paleozoic and modern corals. Microstructural descriptions of samples from the alpine outcrops (Salzkammergut and Dolomites) along with new specimens from Turkey have shown first that the classical wells' schemes have to be re-examined. Accordingly, several investigations based on molecular phylogeny have repeatedly led to the conclusion that, at the family level, the taxonomy inherited from Vaughan and wells cannot be maintained. From an overall evolutionary viewpoint, agreement also exists between microstructural analysis and molecular phylogeny. A recently discovered Triassic family, the Pachythechalids, exhibits highly unexpected skeletal features and microstructures in both septa and walls. Additionally, structural relationships between walls and septa demonstrate a particular mode of growth, with ontogenic priority to the theca. Comparison of the corallite microstructures suggests that most of the Triassic fauna can be derived from this unique family by an evolutionary process during which the septal system became progressively prevalent upon the wall. This monophyly of the modern corals is also well supported by molecular phylogeny. The present concept of Scleractinia has to be re-examined because it cannot include neither Pachythechalids, probably related to the Late Permian Polycoelids, nor some other post-Paleozoic corals, including extant Guyniidae, with long recognized specific structural patterns. 80179 <TITLE>A Comprehensive Phylogenetic Analysis of the Scleractinia (Cnidaria, Anthozoa) Based on Mitochondrial CO1 Sequence Data.</TITLE>

80180 <SOURCE>PLOS ONE 5, 7: e11490.</SOURCE>

80181 <ABSTRACT>Background: Classical morphological taxonomy places the approximately 1400 recognized species of Scleractinia (hard corals) into 27 families, but many aspects of coral evolution remain unclear despite the application of molecular phylogenetic methods. In part, this may be a consequence of such studies focusing on the reef-building (shallow water and zooxanthellate) Scleractinia, and largely ignoring the large number of deep-sea species. To better understand broad patterns of coral evolution, we generated molecular data for a broad and representative range of deep sea scleractinians collected off New Caledonia and Australia during the last decade, and conducted the most comprehensive molecular phylogenetic analysis to date of the order Scleractinia. Conclusions: There was a striking discrepancy between the taxonomic validity of coral families consisting predominantly of deep-sea or shallow-water species. Most families composed predominantly of deep-sea azooxanthellate species were monophyletic in both maximum likelihood and Bayesian analyses but, by contrast (and consistent with previous studies), most families composed predominantly of shallow-water zooxanthellate taxa were polyphyletic, although Acroporidae, Poritidae, Pocilloporidae, and Fungiidae were exceptions to this general pattern. One factor contributing to this inconsistency may be the greater environmental stability of deep-sea environments, effectively removing taxonomic "noise" contributed by phenotypic plasticity. Our phylogenetic analyses imply that the most basal extant scleractinians are azooxanthellate solitary corals from deep-water, their divergence predating that of the robust and complex corals. Deep-sea corals are likely to be critical to understanding

anthozoan evolution and the origins of the Scleractinia. [abbreviated abstract] </ABSTRACT>

80192 <TITLE>Need for a more integrative approach to scleractinian taxonomy.</TITLE>

80193 <SOURCE>Proceedings of the 11th International Coral Reef Symposium, Ft. Lauderdale, Florida, 7-11 July 2008; session 26.</SOURCE>

80194 <ABSTRACT>The history of scleractinian taxonomy is divided into six periods: the original, purely typological, was based on scarce coralla material; the second, starting at the end of nineteenth century, originated with visiting natural habitat and established variability; the third commenced in the 1930s with detailed skeletal study; the fourth began in the 1950s with scuba access to coral habitat; the fifth began in the 1980s following fundamental discoveries in life history and molecular genetics; and the sixth started in 1995, when data from molecular genetics opened a new avenue for scleractinian megataxonomy, contradicting conventional gross-morphology taxonomy but resulting congruent with skeletal histology and ornamentation. Currently, there are four sources of scleractinian taxonomic information: morphology, paleobiology, developmental biology and molecular genetics. Taxonomy is important for understanding scleractinian biodiversity and reef conservation. However, the taxonomy is fragmented and the nomenclature tangled. The e-dimension benefits have not yet been realized and the New Taxonomy not yet arrived for scleractinians. Vision and teamwork are needed for a more integrative taxonomy. The Atlantic Scleractinia Initiative seeks to address the following points: massive sampling, study of the mesophotic habitat, collection access, analysis of phenotypic diversity, life history, geological history, molecular genetics, cyberinfrastructure and education of specialists. 80205 <TITLE>Palaeobiological perspectives on variability and taxonomy of scleractinian corals.</TITLE>

80206 <SOURCE>Palaeoworld 19, 3-4: 333-339.</SOURCE>

80207 <ABSTRACT>Scleractinians are well known for their exceptional variability and difficult taxonomy. Until the end of the nineteenth century, these corals were studied outside their natural habitat. In situ investigation brought to attention their variability and led to description of formae and attempts to depart from the typological taxonomy. Studies commenced in 1950s of extant scleractinians of Jamaica, the South Pacific, Madagascar, the Red Sea, Cuba, and Australia demonstrated instances of coralla unclassifiable in the described species because they possess intermediate characters, and sometimes one corallum exhibits the characteristics of more than one species. Since 1984, discoveries about scleractinian life history and

molecular data further challenged the conventional taxonomy. The coral holobiont is now being studied as a totality of the coral animal, its endosymbiotic zooxanthellae, and its associated community of microorganisms. Molecular genetics and studies of life history combined with morphological variability and variability in geological time are needed for scleractinian taxonomy. The input of palaeontologists with temporal aspect as well as an enormous amount of morphological data is invaluable, as demonstrated by several examples based on detailed morphological observations later supported by molecular and life history information. Efforts to resolve the variability vs. taxonomy dilemma for fossil scleractinians would benefit from further actuopalaeontological work: studies at all levels of biological organization, including ancient DNA and evolutionary genetics, the rich fossil record, fractals and RLQ analysis, palaeopathological research, sclerochronology, the ecology and skeletogenesis of extant deep sea corals. - 80272 <ABSTRACT>Despite the research carried out on living and fossil corals
over recent decades, the phylogenetic history of the Scleractinia
obviously needs important improvements. More than thirty years on, the
evolutionary scheme put forward by Wells (1956) still remains the basic
proposal. In the French treatise by Chevalier (in Grasse, vol. III,
1987), it is clearly said (p. 675) that our present state of knowledge
does not allow us to present an equivalent picture. […] The
project starts with a study of living species, on the basis of which a
correlation between biochemical criteria and characters of the
skeletons will be established, allowing a more efficient use of
morphologic and microstructural features in fossil forms. [presentation

- 80324 <ABSTRACT>Applying the organic matrix concept (Towe, 1972) to the study of coral skeletons leads to a series of results that considerably change our representation of the nature and fine scale organization of coral skeletal components. Since 1941, analogy between fibrous spherulites of inorganic origin and fibrous units that radiate from the "centers of calcification" has gained wide acceptance. Newer research greatly modifies this view, and organic control of fiber growth must be universally accepted. Specific preparations carried out

on modern corals establish that the organic matrix concept explains all visible features in coral fibers, from overall morphology (with organic envelopes present), to control of longitudinal growth of fibers. Cyclic secretion of organic compounds leads to differential solubility between organic rich and organic depleted zones within these biocrystals at a micron scale, allowing very precise descriptions and comparison of development of various types of septa. * Since the 1940s, it has been commonly accepted that the role of centers of calcification is to provide a crystallographic substrate for further growth of aragonite skeletal fibers. Additionally, it is agreed that centers of calcification and septal microstructure have a very high taxonomic potential, but at the same time, they have also frequently been treated as formal descriptive concepts only. Physical chemical measurements (using non destructive methods) and evidence of microstructures obtained by an ultra light etching process complemented by specific biochemical staining allows demonstrating that centers of calcification are present in all species studied. They mostly contain very small, randomly oriented crystals that are always aragonitic, but no direct crystallographic link is seen between crystals from calcification centers and later coating layers of aragonite fibers. * All research areas involving coral skeletons are affected by these changing concepts of skeletogenesis. Thus, the biochemical study of macromolecular mineralizing matrices is important in the study both of coral phylogeny and environmental effects on coral calcification. Another major consequence of this organic and mineral concept of coral skeleton is to provide us with a new basis for studying the fossilization process. [original abstract]

80335 <TITLE>Biomineralization and diagenesis in the Scleractinia: part 2, diagenesis.</TITLE>
80336 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 152-163.</SOURCE>
80337 <ABSTRACT>Diagenesis in scleractinian corals depends on the relative solubility of aragonite and calcite, the presence and chemistry of pore fluids, and the amount, nature and configuration of organic matrix macromolecules within skeleton. Concepts of skeletal diagenesis have been largely based on mineralogic aspects ; thus we recognize that neomorphism of scleractinian skeletal aragonite into calcite results in obliteration of biogenic skeletal microstructure. However, structure can be preserved as aragonitic material, due to isolation, either by non permeable sediment or neomorphic calcite. In calcitized fossil scleractinians, crystal boundaries are seen cutting across biogenic features with resultant destruction of structure. Where dissolution of aragonite and replacement by calcite occurs on a very fine (μm) scale, aragonitic inclusions within calcite commonly outline organic structures. Isolation also allows preservation of whole specimens as aragonite, but fossils totally lacking neomorphic calcite are seldom found, and it is unusual to find aragonitic skeleton with preserved organic matrix within. * Concepts of diagenesis must take into account consequences of biochemical diversity. Organic matrix proteins play several roles in determining the end results of diagenesis, due to their abundance in centers of calcification, their presence in layers of abundant organic proteins within biocrystals and forming protein

envelopes around biocrystal clusters. Earliest diagenesis of aragonite biocrystals begins in skeletal carbonate during the life of the corals, resulting in fusion of aragonite fibers, and loss of organic matter by microbial means or oxidation. There is a common association of reduced sulfur with formerly organic rich areas after breakdown of organic matter by microbes. Where organic material is most abundant, in growth layers or at centers of calcification, its early removal leads to modification of these structures or to calcitization. Growth lamellae, both within and between aragonitic fibers can be exaggerated by calcific neomorphism of aragonite enhanced by early removal of organic matter. [original abstract]</ABSTRACT>

80348 <TITLE>Three-dimensional micro-and nanostructural characteristics of the scleractinian coral skeleton: A biocalcification proxy.</TITLE>

80349 <SOURCE>Acta Palaeontologica Polonica 48, 3: 497-530.</SOURCE>

80350 <ABSTRACT>The contemporary "two-step model" of growth of the scleractinian skeleton is based mostly on transversely sectioned samples. According to this model, many skeletal elements, e.g. septa are formed in two temporally distinct phases represented by (1) "centers of calcification" that are composed of homogenously distributed microcrystalline or/and organic components and serve as scaffolding for the further growth of (2) fibrous skeleton. Based on transverse and longitudinal sections and histochemical staining techniques, I demonstrate herein that in extant corals (i.e. Stephanocyathus, Flabellum, Desmophyllum, "Ceratotrochus", Galaxea, Platygyra), the entire septal skeleton is composed of superimposed layers of mineral and organic-enriched phases. These may be interrupted in some directions of growth but in other directions there is continuity between "centers of calcification" and "fibers", making any distinction between these two structures unclear. As an alternative to the "two-step model", a "layered model" of skeletal growth is proposed, that explains the differences between "centers of calcification" and "fibers" in terms of differential growth dynamics between these regions. Instead of the traditional but inadequate "trabecular" and "centers of calcification" concepts, a distinction between deposits of the Rapid Accretion Front (Draf); which in particular cases can be organized into Centers of Rapid Accretion (CRA), and Thickening Deposits (TD) is proposed. In the dRAF region, mineral components, ca. 50nm in diameter, seem to match the size range of nodular structures recently interpreted as nascent CaCO₃ crystals. Remarkable regularity of the mineral/organic phase alternations (microbanding) in the TD skeleton of zooxanthellate corals and lack of such regular microbanding in azooxanthellate coralla is a promising criterion for distinguishing these two ecological coral groups on a skeletal basis, and one that could be applicable to fossils. 80361 <TITLE>Biogeography of Indo-Pacific larger foraminifera and scleractinian corals: A probabilistic approach to estimating taxonomic diversity, faunal similarity, and sampling bias.</TITLE>
80362 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 122, 1-4: 119-141.</SOURCE>
80363 <ABSTRACT>The eastward decline in the diversity of Indo-Pacific scleractinian corals and larger foraminifera is due primarily to the shallowing of the thermocline and significant cooling of the Equatorial Undercurrent in the eastern Pacific. The coral larvae carried eastward across the Pacific encounter temperatures below 18°C; which is lower than the optimum for the long-term survival of reef-building corals. This thermal barrier to dispersal of the Indo-Pacific fauna is particularly effective in an area within 2000 km west of the Galapagos Islands. Nevertheless, trend-surface analysis of faunal similarity based on the probabilistic index of Raup and Crick (1979) suggests that the modern scleractinian fauna of the eastern Pacific region exhibits a high degree of similarity to that of the Indo-Pacific region. The newly assembled data on the generic occurrence of larger foraminifera and the results of the probabilistic analysis based on the method of Henderson and Heron (1977) indicate that the observed diversity of a fauna constituted, on average, 65% of the true diversity; the remaining 35% can be viewed as a measure of the sampling bias. Last, the maximum north-south range of a genus belonging to modern scleractinian corals or larger foraminifera is 70 ±5° and its east-west range never exceeds the distance that is four times the north-south range. The reason for a correspondence between the maximum latitudinal and longitudinal ranges of genera belonging to these two unrelated groups is believed to lie in the similarity of their dispersal capabilities, which were largely controlled by temperature.</ABSTRACT>

80376 <ABSTRACT>The composition of aragonitic skeletons of some living corals and calcified demosponges is first examined in the way to provide references for following interpretations of preservation states occurring in still aragonitic Triassic and Tertiary fossil records. The analysis of both carbonate lattice and soluble organic compounds, included inside skeletal structures, emphasizes important differences between the two taxonomic groups, inducing different diagenetic trends. Nevertheless, this analytical approach allows us to detect noticeable transformations concerning the composition of biogenic aragonite before the aragonite / calcite inversion.</ABSTRACT>

80415 <ABSTRACT>A new classification of the suborder Amphiastraeina is supposed on the basis of microstructures. The suborder Heterocoeniina is included in the Amphiastraeina, in which two superfamilies are distinguished now. In addition three new species of the genera Confusaforma, Preverastraea and Thecidiosmia are described from the Upper Jurassic to Lower Cretaceous of Poland and Romania.</ABSTRACT>

- 80428 <ABSTRACT>Amphiastraeina are connected with their presumed ancestors, Permian Polycoeliidae, by a transitional link - Triassic corals of the family Pachythecalidae Cuif 1975. During the early Jurassic they differentiated into a few phylogenetic lines and developed certain structural patterns of corallites homeomorphic with those of Rugosa, which had not been, however, recognized in their ancestral group (lonsdaleoid septa and dissepiments, gemmation). Four families are recognized: Amphiastraeidae Ogilvie, Donacosmillidae Krasnov, emend. Roniewicz, Carolastraeidae Eliasova, and Intersmiliidae Melnikova & Roniewicz, fam. n. The earliest Amphiastraeina are described from the ?Hettangian-Sinemurian through the Bajocian and the Callovian of South-East Pamir. One new genus, Prodonacosmilia Melnikova is distinguished.</ABSTRACT>

- 80439 <TITLE>Ontogenetic development of the thecal structures in caryophylliine corals.</TITLE>
- 80440 <SOURCE>Acta Palaeontologica Polonica 40, 1: 19-44.</SOURCE>
- 80441 <ABSTRACT>At the initial stage of ontogeny, in Caryophylliidae (Miocene Caryophyllia salinaria, C. depauperata, Recent C.berteriana) and Flabellidae (Miocene Flabellum roissyanum, Recent Javania cailleti), wall and septa are formed simultaneously, and their trabecular structure is coalesced (marginothecal wall). At subsequent juvenile stage in Caryophylliidae the presence of the extensive exosarc enables formation of costo-septa and, in consequence, formation of trabeculotheca. Trabeculotheca consists of fragments of primordial wall located between the costo-septa. The trabeculothecal segments vanish in the adult stage in the majority of corals when the septothecal wall is formed by thickening of the costo-septa. In others, however, marginotheca can be present throughout the whole ontogenetic sequence (C. salinaria). Most Flabellidae are characterized by limited expression of exosarc and the presence of marginothecal wall up to the adult stage. The origin of 'flabellid' organization in Caryophylliina may result from a simple modification of ontogeny - extention of initial morphology to later ontogenetic stages. Such corals could develop several times, and the Flabellidae may be polyphyletic.</ABSTRACT>

- 80467 <ABSTRACT>La faune corallienne du Maëstrichtien de l'arrondissement de Breznik, Bulgarie du Sud-Ouest est représentée par des Polypiers simples et coloniaux. Le gisement des Coraux coloniaux se trouve dans les sédiments Maëstrichtiens, au voisinage du village Garlo. Les marnes Maëstrichtiennes au Sud-Ouest du v. Krassava et au Nord-Est du v. Yaroslavtzi ne contiennent que des Polypiers simples. Prédominent les Polypiers de forme cyclolitoides. On donne la description de 6 espèces, qui appartiennent aux genres Cunnolites Barrère et Plesiocunnolites Alloiteau: Cunnolites sororius (Quenstedt), Plesiocunnolites undulatus (Goldfuss), Pl. undu-latifomis (Oppenheim), Pl. platystoma (Quenstedt), Pl. mitissimus (Oppenheim) et Pl. reissi (Fromental).</ABSTRACT>

80531 <SOURCE>Bulletin de la Societe geologique de France 7, 12, 2: 378-382.</SOURCE>
80532 <ABSTRACT>On décrit deux sortes d#39;anomalies. L#39;une est la formation de bourgeons secondaires abortifs chez les Madréporaires Microsolénides typiquement solitaires. L#39;autre concerne des perturbations observées dans l#39;élaboration de la face inférieure et dans la disposition des septes de cette face chez Chomatoseris: elles sont dues à la persistance d#39;un important support de la planula; celui-ci par ses dimensions excessives, entrave alors la fermeture normale de la face inférieure du Polypier. Les anomalies présentées ici, malgré une certaine coïncidence avec l#39;ontogenèse des Madréporaires, sont causées essentiellement par des facteurs du milieu extérieur.</ABSTRACT>

80571 <ABSTRACT>[born] 26. Februar 1915 in Baden near Vienna, Austria [died] 06. July 2004 in Münster, Germany. * Prof. Dr. Alexander von Schoupe, Nestor of German coral research and long standing member of the International Association for the Study of Fossil Cnidaria and Porifera, was an international recommended and esteemed scientist as well as a passionate researcher and University teacher. He has been revered by his students and colleagues, and he was always a trustworthy friend. * Alexander von Schoupe studied Geology, Paleontology and Mineralogy at the Karl-Franzens University in Graz, supervised by the famous Prof. Dr. Franz Heritsch. On May, 26. 1939, after finishing his thesis 'Die Coelenteratafauna des e-gamma der Karnischen Alpen'; he became Dr. phil. and assistant at the Geological Institute Graz. During the world war II he was assigned to the German Air Force where he served as meteorologist in a remote scout plane. He survived three downings. * After the war he returned to Graz. In 1948 and with an investigation on morphogenesis and systematics of the coral genus *Thamnophyllum* [Die Thamnophyllen und ihre Beziehung zur Gruppe des *Cyathophyllum caespitosum*], the *venia legendi* in Palaeontology was bestowed on him and, following in 1952, the *venia legendi* in Geology with a paper on hydrogeological studies on the genesis of the

Gleichenberg mineral springs [Hydrogeologische Studien zur Genesis der Heilquellen von Gleichenberg]. * In 1953 Alexander von Schoupe was appointed to the University at Münster to establish the branch of Palaeontology at the Geologisch-Paläontologisches Institut and Museum [Director Prof. Dr. Franz Lotze] where, in 1956, he became extraordinary professor and in 1965 "wissenschaftlicher Rat"; and senior professor. Between 1973-1975 he was the Dean of the " Geosciences". [excerpts from extensive obituary]</ABSTRACT>

80582 <TITLE>The relationship of the scleractinian corals to the rugose corals.</TITLE>

80583 <SOURCE>Paleobiology 06, 2: 146-160.</SOURCE>

80584 <ABSTRACT>The Mesozoic-Cenozoic coral Order Scleractinia has been suggested to have originated or evolved (1) by direct descent from the Paleozoic Order Rugosa or (2) by the development of a skeleton in members of one of the anemone groups that probably have existed throughout Phanerozoic time. In spite of much work on the subject, advocates of the direct descent hypothesis have failed to find convincing evidence of this relationship. Critical points are:(1) Rugosan septal insertion is serial; Scleractinian insertion is cyclic; no intermediate stages have been demonstrated. Apparent intermediates are Scleractinia having bilateral cyclic insertion or teratological Rugosa.(2) There is convincing evidence that the skeletons of many Rugosa were calcitic and none are known to be or to have been aragonitic. In contrast, the skeletons of all living Scleractinia are aragonitic and there is evidence that fossil scleractinia were aragonitic also. The mineralogic difference is almost certainly due to intrinsic biologic factors.(3) No early Triassic corals of either group are known. This fact is not compelling (by itself) but is important in connection with points 1 and 2, because, given direct descent, both changes took place during this only stage in history of the two groups in which there are no known corals. (Original summary)</ABSTRACT>

80595 <TITLE>Sclerosponges May Hold New Keys to Marine Paleoclimaze.</TITLE>

80596 <SOURCE>EOS, Transactions, American Geophysical Union 79: 633-636.</SOURCE>

80597 <ABSTRACT>This paper reports on a meeting of March 1998 to discuss the use of sclerosponges to reveal climatic changes of the past few thousand years. The advantages of using these sponges are that the basal skeleton is secreted in carbon and oxygen isotopic equilibrium with the environment, they are very long lived (up to 4,000 years estimated), and they live in a range of different depths. Unlike those of scleractinians the isotopic signatures of their skeletons are apparently unaffected by vital effects. They grow at between 0.2 mm and 1 mm per year depending on depth. The growth increments are most

- successfully dated by mass spectrometric measurements or uranium series isotopes.</ABSTRACT>

- 80609 <SOURCE>Berliner geowissenschaftliche Abhandlungen A060: 151-193.</SOURCE>
- 80610 <ABSTRACT>The demosponges with a thalamid and aragonitic basal skeleton, and a trabecular internal structure ("Sphinctozoa" pars) are revised. The following new taxa are proposed: Stylothalamiidae n.fam. (type genus Stylothalamia Ott 1967); Menathalamia caniegoensis n.gen., n.sp.; Vaceletiidae n.fam. (type genus Vaceletia Pickett 1982); Vascothalamia arayaensis n.gen., n.sp. (attributed to the family Verticillitidae Steinmann 1882); Murguithalamida n. ordo; Murguithalamiidae n.fam.; Murguithalamia jugoensis n.gen., n.sp.; Boikothalamiidae n.fam. and Boikothalamia n.gen. (type species Verticillites convexus Bojko 1979). All new species come from the Albian of Northern Spain. Murguithalamia jugoensis n.gen., n.sp. was proved having pseudomorphs of originally siliceous triaene megascleres. Vascothalamia arayaensis n.gen., n.sp. was found having pseudomorphs of monaxone siliceous megascleres. Considering these findings as well as the living "sphinctozoa" Vaceletia crypta (Vacelet 1977) - it is obvious that the demosponges with a thalamid and aragonitic basal skeleton, and a trabecular internal structure are polyphyletic. The taxa were attributed therefore partly to the subclass Ceractinomorpha Levi 1973 (order Verticillitida Termier et Termier 1977 with the families Verticillitidae Steinmann 1882, Vaceletiidae n.fam. and Stylothalamiidae n.fam.) and partly to the subclass Tetractinomorpha Levi 1973 (order Murguithalamida n. ordo with the families Murguithalamiidae n.fam. and Boikothalamidae n.fam.).</ABSTRACT>

- 80623 <ABSTRACT>The monograph embracing all the information on Sphinctozoa, a very important taxon in evolutionary and biostratigraphical aspects, was created for the first time in the USSR. The general part of the monograph includes the outlines devoted to the problems of morphology, systematics, paleontology and the stratigraphical significance of Sphinctozoa. The description of all the species of Sphinctozoa known in the USSR (from the Carboniferous to the Jurassic and from the Far Eastern USSR to the Crimea inclusively) is given in another part of the monograph, which contains the regional geological outlines. In some cases the revision of the higher taxa at the level of "genus" -

- " is given. The separate chapter represents the materials related to the discussion on the nature of Sphinctozoa among both the specialists from different countries and the authors of this monograph. The book is richly illustrated, includes text figures and 65 plates, traces, the list of references is complete. </ABSTRACT>

- 80636 <ABSTRACT>Des fossiles de position et affinités zoologiques incertaines, ayant en commun un ensemble de caractères morphologiques (porosité du squelette, loges, cavité axiale, etc.), tels que les Archaeocyatha, Sphinctozoa, Aphrosalpingoidea, Soanitida et Receptaculitidae, pourraient constituer le plus ancien groupe de Métazoaires (Archaeata). Pour rechercher s'il n'existerait pas également des similitudes de constitution du squelette, des recherches sont menées en microscopie électronique et microscopie optique (sur lames ultra-polies). Sont donnés ici les premiers résultats de l'étude de quelques Pharétones, Barroisia anastomosans, Tremacystia d'orbigny, Amblysiphonella sp., Preverticillites sp. comparés avec Petrobiona, Eponge calcaire actuelle. Toutes ces formes ont un squelette fibreux, dont les éléments peuvent être classés en trois groupes: (1) fibres droites fines - pas de spicules (Sphinctozoaires du Permien); (2) fibres droites ténues - pas de spicules (Petrobiona); (3) fibres à bosselures avec fins spicules monaxones et spicules triaxones (Sphaerocoelidae - Barroisia, Tremacystia - du Crétacé). L'hypothèse de regroupement de ces formes n'est pas vérifiée au niveau de la microstructure.</ABSTRACT>

80895 <SOURCE>Systema Porifera: A Guide to the Classification of Sponges [Hooper J. N. A. & Van Soest R. W. M. (eds); Kluwer Academic/Plenum Publishers, New York]: 69-70.</SOURCE>
80896 <ABSTRACT>Stromatoporoidea Nicholson & Murie (?Porifera, ?Demospongiae) are calcareous skeletal remains of organisms present during the Palaeozoic to Mesozoic, comprising sponge-like taxa with hypercalcified layered skeletons that were important to reef-building. Earlier (Palaeozoic) forms lack spicules but some of the later (Mesozoic) taxa have siliceous monaxonomic or tetraxonic spicules in addition to calcitic basal skeletons, inferring affinities to Demospongiae. 'Stromatoporoids' has been used at various levels (ordinal, class, and subphylum) within the phylum Porifera, but also within other "lower" marine invertebrate phyla at various times. The contemporary hypothesis is that these life forms may represent a grade (not a clade) of poriferan construction, although it is also recognized that there may be fundamental differences between the Palaeozoic and Mesozoic stromatoporoid faunas, such that this grade of skeletal construction may not be homologous, and the taxon may be a completely artificial construct. Some stromatoporoids have also been associated with the Calcareia and also the 'sphinctozoan' grade of construction. Only a brief overview is provided although the stromatoporoids include about 110 genera in seven orders.</ABSTRACT>

80908 <SOURCE>Journal of Paleontology 75, 6: 1079-1089.</SOURCE>
80909 <ABSTRACT>The history of research on the "true" stromatoporoids, a presumably monophyletic group of sponges that

occurred from the Ordovician through the Devonian, is examined in detail. Stromatoporoid published research is summarized in five categories: quantity of publication; biological affinities; systematics; skeletal microstructure; and paleoecology. Quantity of publication is measured from each of the 75 years. Moderate levels of publication in the late 1920s and 1930s declined in the early 1940s, and were reduced to zero for four years due to the impact of world war II. Levels similar to that of the 1930s returned in the 1950s, after which there was an overall increase until the mid-1980s, when levels began a decrease that persists today. The proportion of research on paleoecology has increased as research on systematics decreased through time. Post-Devonian forms assigned to the stromatoporoids are a polyphyletic grouping of several apparently unrelated taxa, possibly representing both Porifera and Cnidaria. Publications on the post-Devonian stromatoporoids amount to less than one-third that on the true stromatoporoids during the same 75 years.

- 81026 <ABSTRACT>The ontogenetic changes expressed in the earliest Amphipora-skeleton growth stages suggest that the observed successions can be very different from those of common stromatoporoids. The amphiporid organisms built first their bottom discs or directly the complex first chambers (diameters ~0.2 mm), and these structures were directly continued by upright growth of first single tubes. The first occurrences of gradually developing amphiporid skeleton fiber meshworks were concentrated in the zone of metamorphosis, where the first tubes decayed. The attributes of adult amphiporid stages (axial canal and sparsely perforated outer casings or walls) developed with a little delay. The Amphipora stems increased mainly during the first millimeters of their length (to ~1.5-2 mm), but further increase of the stems (to ~3 or 5 mm) was a very slow process. It can be suggested that amphiporids can be linked to very old ancestors, somewhere around archaeocyaths or common metazoan sources at ~0.8 Ga.</ABSTRACT>

tests.</TITLE>
81077 <SOURCE>Paleobiology 17: 121-132</SOURCE>
81078 <ABSTRACT>[The diameters of the channels at branch points can be used
to test 3 alternative models of astrorhizal function. These diameters
do not support a model of diffusive function or a bulk flow system.
They do support a model based on "Murray's Law" that "
simultaneously minimizes resistance to flow and some volume-related
cost function". "The most parsimonious hypothesis of function,
that the fluid transport system was associated with suspension feeding,
implies strong similarities between the structure of the stromatoproid
animal and living sponges".]</ABSTRACT>

81155 <SOURCE>Palaeontology 36: 201-229.</SOURCE>
81156 <ABSTRACT>The genus Stromatopora is interpreted in terms of the type specimens of the type species as dominated by oblique elements in a cassiculate structure. Cellular structure is distinct from microreticulate structure and separates the order Stromatoporida from the order Syringostromatida which evolved from the densastromatids. Parallelostroma gave rise to Coenostroma, Habrostroma, Syringostroma, Columnostroma, Parallelopora in a Late Silurian-Early Devonian radiation. In Early and Middle Devonian the stromatoporids radiated into Lineastoma, Arctostroma, Pseudotrurpetostroma, Glyptostromoides, Taleastroma. Each of these genera and also Salairella, Ferestromatopora, and Syringostromella is rediagnosed and discussed.</ABSTRACT>

81168 <SOURCE>International Union of Geological sciences Publication 33 [Norford B.S. (ed.): Correlation chart and biostratigraphy of the Silurian rocks of Canada]: 26-27.</SOURCE>
81169 <ABSTRACT>Zonation of the Silurian rocks on the basis of Stromatoporoid ranges is not possible in the present state of knowledge but faunas have been described from all the major stages. Early Llandovery faunas are known from Anticosti Island, Manitoba, Baffin Island and Lake Temiskaming. Late Llandovery faunas are cosmopolitan, spread by transgressing seas across the platforms, and marked by the adaptive radiation of the actinostromatids and stromatoporids. Wenlock faunas characterized by densastromatids and Parallelostroma are found in eastern Quebec, southern Ontario, and Lake Temiskaming. The arctic islands, southwestern Ontario and eastern Quebec have faunas of Ludlow age characterized by many clathrodictyonids and Plexodictyon. Pridoli faunas are confined to southern and eastern Quebec in the Appalachian Mountain areas.</ABSTRACT>

81180 <TITLE>The applications of stromatoporoid palaeobiology in palaeoenvironmental analysis.</TITLE>
81181 <SOURCE>Palaeontology 31, 3: 509-544.</SOURCE>
81182 <ABSTRACT>Stromatoporoids are epibenthic calcified sponges in many Phanerozoic (especially Palaeozoic) reef, and reef-related environments, and may be used as tools for all scales of palaeoenvironmental analysis. Palaeozoic stromatoporoid classification uses the calcified skeleton, and although higher level taxa may be convergent, genera and species are normally readily identifiable and have palaeobiological utility. A hierarchical growth-form classification of stromatoporoids comprises: Level 1 (outline forms: laminar, tabular, domical, columnar, bulbous, defined with ratio limits; and dendroid, expanding conical, digitate and irregular); Level 2 (ornament, as papillae, mamelons and protuberants, give an increasing degree of disruption of the outline); and Level 3 (growth patterns of smooth and ragged margins, enveloping and non-enveloping laminations, coalescence and anastomosing). Inappropriate growth form terms in current use are rejected especially massive and encrusting. Stromatoporoid palaeobiology applied at local scale aids determination of relative degree of contemporaneous turbulence and sedimentation; community scale study of stromatoporoids promotes comparisons between palaeoenvironments in reef and reef-related facies. Palaeozoic stromatoporoids may aid regional and even global event recognition including changes in ocean states. Major gaps in knowledge are growth rates and whether stromatoporoids were photosensitive and /or photosymbiotic.</ABSTRACT>

81207 <SOURCE>Lethaia 27: 1-10.</SOURCE>
81208 <ABSTRACT>Modern coralline sponges secrete a skeleton by means of a basal pinacoderm, intracellularly, or inside the soft tissue on an organic matrix. The examination of terminal growth surfaces of

- stromatoporoids indicates that soft tissue in laminate and amalgamate forms occupied the upper galleries and that the skeletal elements were secreted within soft tissue on an organic matrix. The stromatoporellids and clathrodictyids secreted the skeleton in modules that are homologous to the chambers of a sphinctozoan. In stromatoporellids the module was bounded by a floor that formed the upper layer of the tripartite lamina below and a roof that became the lower layer of the next lamina; it further included the intervening pillars. In clathrodictyids the module had only a roof and pillars and the laminae are single layers.</ABSTRACT>

81219 <TITLE>A computer model for skeletal growth of stromatoporoids.</TITLE>
81220 <SOURCE>Palaeontology 37, 2: 409-423.</SOURCE>
81221 <ABSTRACT>[A model of simple accretionary laminar growth can be developed based on probabilistic accretion of pixels on a raster array. Experiments with the model allow the effects of sedimentation and various alternative growth algorithms to be simulated. The model can be validated, with some reservations, on theoretical and empirical bases: the simulations show similarities to observed stromatoporellid morphologies. The results show that morphology is strongly influenced by the pattern of sedimentation and that the stromatoporoids required a local pause in sedimentation in order to become established, and that they were integrated organisms with a low level of organization allowing a degree of autonomy of modular growth.]</ABSTRACT>

81362 <TITLE>Functional and environmental significance of skeletal morphology in stromatoporoids.</TITLE>
81363 <SOURCE>Wales University, unpublished Ph.D. thesis.</SOURCE>
81364 <ABSTRACT>Stromatoporoids are important in Lower Palaeozoic reefs and related facies, and the palaeoecology of their external form is studied here using examples from the Ordovician and Silurian of the Oslo region, the Silurian of Gotland and the Devonian of Belgium. * A new classification, of shape (bearing no relation to taxonomic schemes) distinguishes laminar, domical, bulbous and dendroid shapes defined by measurement of basal and vertical dimensions. Each has subdivisions, most importantly being the distinction between smooth (enveloping) and ragged (non-enveloping) latilaminae, interpreted to be a response to sedimentation. * A parameterization scheme relates laminar, domical and bulbous forms in a simple triangular display, in terms of basal, vertical and diagonal extension. * Flume experiments on model stromatoporoids, statistical analysis of field data and detailed hand specimen and thin section studies show that: (1) laminar forms were susceptible to sedimentation but were stable in high energy conditions. In deep water they were possibly limited by low light intensity; (2) domical forms were very stable and possessed a sediment shedding capability; with laminar forms their shape has a strong taxonomic component in some cases; (3) bulbous forms were unstable and generally reflect quiet water conditions; complex bulbous forms are found in high energy situations where they show overturning; (4) dendroid varieties were delicate and well suited to environments with higher sedimentation rates in areas of low turbulence. * Substrate composition and surface shape were important factors in the distribution of stromatoporoid morphotypes. Sandy substrates show susceptibility to scour around stromatoporoids leading to burial of domical and bulbous forms in environments of water flow, but low-profile laminar types were less affected. Dendroid forms were infrequently affected by substantial currents. Muddy substrates scoured less, and stromatoporoids were put into transport more easily, but if partly buried in mud, stromatoporoids were very stable. * The environments of stromatoporoids were generally open marine, although in certain restricted conditions examples show distinct morphological peculiarities (irregularity and extreme thinness) suggesting influence of other limiting factors, such as salinity, food supply, temperature and water aeration.</ABSTRACT>

81427 <TITLE>Note on "Nummulosphere" by R. Kirkpatrick.</TITLE>
81428 <SOURCE>FC&P 13, 2: 28.</SOURCE>
81429 <ABSTRACT>Although I thought that I was reasonably well acquainted with the paleontological literature on stromatoporoids, one book containing extensive discussions on these organisms had escaped my notice until this summer. I knew by rumour that it existed but had not taken the time to verify its existence until, by accident, I came across it in the library. I recommend it to all stromatoporoid specialists as an essential part of the history of their science. * It is Randolph Kirkpatrick's book "The Nummulosphere" published by the author in three parts or volumes - the first two in 1913 and the third in 1917. Kirkpatrick will be remembered by stromatoporoid paleontologists for the beautiful work that he did describing Merlia normani, the sclerosponge from Porto Santo Island near Madeira. Kirkpatrick could see the structure of Nummulites in all the rocks he examined including limestones, sandstones, slates, metamorphic rocks,

lavas, plutonic igneous rocks and meteorites. In the numerous igneous rocks that I have examined I have found them to be disguised (? colonial) foraminifera (vol. I, p. 52). He concluded that the whole crust of the Earth is composed of Nummulitic limestone changed in various ways and was therefore deposited out of an ocean. The reader of vol. III will find that the macrostructural features of stromatoproids are produced inorganically like concretions in limestone and that both the structural elements and the gallery filling are composed of Nummulites, like most of the rest of the world. Kirkpatrick's viewpoints on stromatoproids has matured from the first to third volumes for in the first volume he equates them with both Eozoon and nummulites as follows: I cannot find a single point of zoological difference between Eozoon canadense Dawson and Stromatopora concentrica Goldfuss. In both there are layers of Nummulite shells of the same structure and size (p. 26). He then proceeds to write about the stromatoproid type of nummulite and we find that Jurassic Oolites and Chalk are probably mainly masses of Stromatoproids, yet it is not possible to define the shapes of specimens, nor even of reefs (p. 27). * The book throws some light on Kirkpatrick's note in Nature (1912) stating that he had discovered spicules in stromatoproids and they must therefore be sponges. No one since has been able to verify this observation. It appears that Randolph Kirkpatrick was capable of seeing structures in rocks that other scientists have missed. * Here is a book that illustrates and describes such stromatoproid species as Stromatopora concentrica, Stromatoporella eifeliensis, Clathrodictyon striatellum, Idiostroma oculatum and discusses the Caenopora problem yet I have never seen it referenced in a synonymy - I wonder why. [historical note, full text]

- 81492 <TITLE>Stromatoporoid biometrics using image analysis software: A first order approach.</TITLE>
- 81493 <SOURCE>Computers & Geosciences 36, 4: 550-558.</SOURCE>
- 81494 <ABSTRACT>Strommetric is a new image analysis computer program that performs morphometric measurements of stromatoporoid sponges. The program measures 15 features of skeletal elements (pillars and laminae)

visible in both longitudinal and transverse thin sections. The software is implemented in C++, using the Open Computer Vision (OpenCV) library. The image analysis system distinguishes skeletal elements from sparry calcite using Otsu's method for image thresholding. More than 150 photos of thin sections were used as a test set, from which 36,159 measurements were obtained. The software provided about one hundred times more data than the current method applied until now. The data obtained are reproducible, even if the work is repeated by different workers. Thus the method makes the biometric studies of stromatoporoids objective.

81506 <SOURCE>FC#38;P 22, 2: 95-96.</SOURCE>

81507 <ABSTRACT>These three generic names have been applied to the same taxon. They were proposed for clathrodicytids with simple laminae and simple pillars confined to an interlaminar space. Both authors realized that the discrepancy between the type species of Simplexodictyon Bogoyavlenskaya and its diagnosis required the establishment of a new genus to contain those species of this genus that did not have double laminae. The type species that Stearn used for Petrostroma (later corrected to Petridiostroma to resolve the homonymy with Petrostroma Doderlein), P. simplex (Nestor), is placed by Lessovaya (1991) in Faciledictyon. [Many journals are now not available until months after the publications dates that appear on their covers. This situation does not appear to be covered satisfactorily by Chapter V of the Code of Zoological Nomenclature. [first and last fragment of nomenclatorial note]</ABSTRACT>

81519 <SOURCE>FC#38;P 23, 1.1: 97.</SOURCE>

81520 <ABSTRACT>webby, Stearn #38; Zhen (1993: 122) mention a small collection of material held by the Queensland Museum. These were part of a large collection of fossil material acquired from the late Mr. F.S. (Stan) Colliver. Included in this collection were seven stromatoporoid specimens labelled #34; used by Betty Ripper in her publication #34;. Review of E.A. Ripper material (webby, Stearn #38; Zhen, 1933) indicates that one of the specimens part of a holotype and a second is a mentioned specimen. The remaining four are untraceable. All are partial skeletons, which have been cut, presumably for thin sections. [introductory part of a short note]</ABSTRACT>

81546 <ABSTRACT>Actinostromatid stromatoporoids are constructed of vertical and horizontal rods, called pillars and colliculi. There are three families in the order: Pseudolabechiidae, Actinostromellidae, and Actinostromatidae. Two evolutionary schemes are presented, one traditional, and one containing some new ideas. Plumatalinia is moved from the Labechiida to the Actinostromatida. Plectostroma and Densastroma are poorly understood, and probably represent several genera.</ABSTRACT>

81558 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 319-328.</SOURCE>
81559 <ABSTRACT>The order Clathrodictyida is subdivided into five families: Actinodictyidae, Clathrodictyidae, Gerronostromatidae, Atelodictyidae and Tienodictyidae. The name Actinodictyidae has priority over Ecclimadictyidae. The first clathrodictyids (Clathrodictyon and Ecclimadictyon) with inflected laminae and weakly differentiated pillars appeared at the end of the middle Ordovician. They probably descended from labechiids but the separation could have taken place in the families Clathrodictyidae and Actinodictyidae. Later on they were gradually replaced by the clathrodictyids with well differentiated planar laminae and simple (Gerronostromatidae) or complicated pillars (Atelodictyidae, Tienodictyidae), prevailing in the Devonian.</ABSTRACT>

81583 <TITLE>On the system of the family Clathrodictyidae Kuhn 1939.</TITLE>
81584 <SOURCE>Russian Geology and Geophysics 37, 2: 59-67. [translation of Geologiya i Geofizika]</SOURCE>
81585 <ABSTRACT>The family Clathrodictyidae Kuhn 1939, widespread in Paleozoic deposits in many regions of the planet, is revised, and a new system for it is proposed. A new phylogenetic scheme is suggested for this family, and genus diagnoses are improved. This paper presents a complete species composition of the genera assigned to the family and indicates the species synonyms. Geological and geographical distribution of species is refined. It is proved that some of the genera are not well established and that they are mere synonyms of previously recognized ones. * The classification scheme introduced is as follows: subfamily Clathrodictyinae (Clathrodictyon, Simplexodictyon, Petridiostroma, Stelodictyon, Coenellostroma, Oslodictyon, Clavidictyon); subfamily Tienodictyinae (Tienodictyon, Intexodictyon); subfamily Ecclimadictyoniinae (Ecclimadictyon, Plexodictyon, Yabeodictyon, Neobeabtricia); subfamily Actinodictyinae (Actinodictyon, Labechiina).</ABSTRACT>

81661 <TITLE>The relationship between stromatoporoids and heliolitids.</TITLE>
81662 <SOURCE>Lethaia 14, 1: 21-25.</SOURCE>
81663 <ABSTRACT>The dense fibro-lamellar skeleton of lophiostromatids (Stromatoporoidea) is closely similar to the trabecular skeleton of protaraeids (Heliolitoidea) and, respectively, the cystose skeleton of labechiids is similar to that of proporids. They can be interpreted as different types of basal exoskeleton of colonial coelenterates. The main difference between these ancient stromatoporoids and heliolitids is in the arrangement of zooids in the colony, that in the heliolitids enabled them to participate in skeleton building, which was not possible in the stromatoporoids. The stratigraphical distribution supports the supposition of their common origin. [original abstract]

- 81792 <SOURCE>Journal of Paleontology 73, 4: 580-597.
<http://www.jstor.org/pss/1306758></SOURCE>
- 81793 <ABSTRACT>During growth of colonial corals, the basic organization of skeletal elements was determined by inherent factors, but arrangement of corallites within a colony could be affected if environmental change induced a modified growth form. Comparisons of internal and external characters during colony development indicate how environmental and genetic factors determined growth form. The results of these comparisons have implications for understanding of colony integration, functional morphology, and systematics. This study is based on serially sectioned coralla of the cerioid tabulate Paleofavosites subelongus, from the uppermost Ordovician to lowermost Silurian of the east-central United States. Colony growth form resulted from changes in maximum growth angle of marginal corallites, and in the shape of the growth surface. These features were coordinated with corallite characters and were dependent on variation in corallite growth. At the same time that a colony became broader by expanding its maximum growth angle and developing a taller growth surface, its corallites became larger, more new corallites were initiated, and recently initiated corallites expanded more rapidly. When a colony's maximum growth angle was reduced and the growth surface became flatter, corallites also became smaller, fewer corallites were initiated, and those corallites that were recently initiated expanded slowly. Genetic constraint of growth is illustrated by consistent patterns of initial colony growth, and by relationships among characters of internal and external morphology. Frequent small-scale variations in growth angle and growth surface height:width during astogeny indicate fluctuating environmental factors. Sedimentation and subsidence of the colony were probably the major environmental controls on form. [original abstract]</ABSTRACT>

81845 <ABSTRACT>The study of Auloporida from the Devonian of the Ferques area, in the north of France, reveals the presence of a dodecal symmetry in the constitution of the walls of Thecostegites bouchardi and Aulopora serpens. This observation corroborates the discovery of fossilized tentacles in a Favosites by Copper, and adds information about the presence of 12 rows of septal spines in numerous Tabulata. So the dodecal symmetry seems to be a significant character of Tabulata.</ABSTRACT>

</TITLE>
- 81870 <SOURCE>Palaeontology 50, 6: 1375-1380.</SOURCE>
81871 <ABSTRACT>Tube-like traces of organisms belonging to the ichnogenus Chaetosalpinx Sokolov have been considered in the literature as commensal endobiontic organisms of tabulate corals. Their position between the corallites (or sometimes within the septa), perforation of the host's skeleton and soft tissue, modification of its phenotype and a possible inhibition of its growth show that the relationship between these organisms and tabulate corals can best be interpreted as parasitism rather than commensalism, as previously suggested. Such an interpretation may be extended to the ichnogenera Helicosalpinx Oekentorp and Actinosalpinx Sokolov, which show identical placement within the host colony and similar features, such as the absence of their own wall.</ABSTRACT>

81882 <TITLE>Estimation of palaeoenvironmental changes: can analysis of distribution of tabulae in tabulates be a tool?</TITLE>
- 81883 <SOURCE>Geological Society, London, Special Publications 275: 275-281.
</SOURCE>
- 81884 <ABSTRACT>Growth periodicity (cyclomorphic variation) in corals is expressed by various features, among them changes in the distribution of tabulae. A method potentially useful in analysis of periodical environmental changes is proposed herein. Measurement of spaces between tabulae in tabulate corals and preparation of a histogram converted into a trend curve may show relative periodical fluctuations of the environment. Such an analysis, exemplified here on Givetian Pachyfavosites sp. from the Avesnois (northern France), shows that this method may be used as a tool for estimation of environmental changes.

- 81909 <SOURCE>Palaeontology 32, 4: 745-764.</SOURCE>
- 81910 <ABSTRACT>Phylogenetic analysis of the extinct anthozoan clade Tabulata yields new hypotheses concerning their pattern of diversification in the Ordovician. Two separate phylogenetic analyses, one based on primitive rugose corals as the outgroup (RUGSGRPS), and the other based on Lichenaria as the ancestral tabulate coral (LICHGRPS) yielded different phylogenies. The phylogenies generated are broadly different from previously proposed phylogenies based on possibly subjective morphological interpretations, and on biostratigraphical and / or biogeographical hypotheses alone. Character analysis based on consistency index (a measure of homoplasy of characters) yielded four suites of morphological characters: (1) suites with a high consistency index (CI) that differentiate major groups; (2) suites with a high CI that differentiate subgroups; (3) suites with a low CI that differentiate major groups and (4) suites with a low CI that differentiate subgroups. Therefore, CI does not necessarily correspond with the potential for differentiating major groups. The most useful characters in differentiating major groups of Ordovician tabulates are architecture, wall thickness, mural pores, microstructure, corallite shape, and coenenchyme, whereas those not particularly useful in differentiating major groups are tabulae, septa, rows of septal spines, columella, and stereozone. The phylogentic analyses corroborate the taxonomic integrity of the presently defined Auloporida, Favositida, Halysitida, Heliolitida and most Sarcinulida and falsify the taxonomic integrity of the Chaetetida and the Lichenariida. As presently defined the Halysitida should be separated from Heliolitida.</ABSTRACT>

81960 <TITLE>Ultrastructure of the walls, tabulae and "polyps" in Early Silurian Favosites from Anticosti Island, Canada.</TITLE>
81961 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 301-308. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 1]</SOURCE>
81962 <ABSTRACT>SEM and ultra-thin section examination of the fossilized "polyps", corallite walls and tabulae in Late Llandovery (Silurian, Aeronian) Favosites from the Jupiter Formation on Anticosti Island reveal the following observations not previously discovered or described: (1), the "polyps" have a very finely radial and concentrically wrinkled surficial structure along the basal portions, but not on the "tentacles"; (2), the "polyps" are discrete and separate from the uppermost tabulae on which they rest, and are not produced as modifications of the tabulae nor the septal ridges; (3), the "polyps" occur only on top of the last tabula, with no remnants remaining on or between abandoned tabulae below; (4), the "polyps" consist of sparry calcite and are not microlamellar like the walls or tabulae; (5), the walls and tabulae consist of flattened microlamellae like those in Favosites gothlandicus; (6), within the preserved "polyps" are small yellow spherules (10-20µm), of possible cyanobacterial or algal origin.

Our tentative explanation for these remarkable structures is that they reflect fortuitous burial and conservation which permitted early infilling or saturation by aragonite or calcite of the soft tissues, thereby preserving the 12-fold symmetry and morphology of the soft polyps, which once rested on the tabulae.</ABSTRACT>

81974 <SOURCE>Mitt. Ges. Geol.-Bergbaustud. Osterr. 39/40: 15-28.</SOURCE>

81975 <ABSTRACT>The mode of growth of the adult corallum of Catenipora micropora from the Llandoveryan of NE-Iran (Shirgesht area) is demonstrated. The investigation of intraspecific variabilities of corallite geometries indicates, that intraserial variabilities (variability within a "plain") are not significant different from interserial variabilities (variability in "space"). Biometric data sets show the same variability of dimensions throughout the entire adult part. Compared with younger parts of the colony the older ones show a better defined data range. Size and geometry of the ring shaped chains of corallites (lacunae) are interpreted as genetically determined co-processes of all corallites (polyps) forming a lacuna. This process is subordinated the simple polyp. The investigation demonstrates that one section parallel and one vertical to the growth direction of the corallum is sufficient for taxonomic characterization.</ABSTRACT>

81986 <TITLE>Growth strategies and colonial form in tabulate corals.</TITLE>

81987 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 179-191.</SOURCE>

81988 <ABSTRACT>Adaptive strategies for colony development (growth strategies) in tabulate corals can be viewed in terms of two end-members, peripheral growth and medial growth. In peripheral growth, new corallites are preferentially offset at the colony margin, whereas in medial growth, new corallites are principally offset between earlier, diverging corallites. Many tabulate coral species were obligate followers of one or other strategy, whilst others could switch or vary growth between the two strategies. Growth strategy was a factor in recruitment success on different types of substrate. Colonial form was a function of growth strategy, offset density and corallite growth control, moderated during astogeny to a greater or lesser degree by environmental factors, principally sediment mobility and rate of substrate aggradation. A wide range of colonial growth-forms, with a considerable area of overlap, could result from both strategies. The interaction of growth strategy and environment is illustrated by two contrasting examples from the Silurian. A deep water (>50-60m) substrate, with no net sediment aggradation over a 15-20yr period, from

the Llandoverly of County Mayo, Ireland, was dominated by tabulate corals with a peripheral growth strategy and tabular to domal growth-forms. This environment was probably close to the base of the photic zone. Wenlock patch reefs in the Welsh Borderland of England developed in water <30m depth. Here, different strategies and growth-forms dominated the major phases of patch reef growth during periods of continuous sea-floor colonization. Peripheral growth and tabular form dominated in the initiation stage; a more even spread of strategies and a shift to domal and bulbous growth-forms, together with the highest percentage of halysitids occurred in the reef core; and medial growth dominated in the reef margin, with a wide range of growth-forms including a significant percentage of nodular colonies.

82026 <SOURCE>Neues Jahrbuch f. Geologie u. Palaeontologie, Monatshefte 1995, 4: 193-204.</SOURCE>

82027 <ABSTRACT>A microstructural study of the holotype of Striatopora immota Moore & Jeffords 1945, type species of Parastriatoporella Tchudinova 1959, shows the entirely fibrous constitution of the skeleton of this genus. In the axial zone, the wall consists of a non-trabecular water-jet sclerenchyme, in the peripheral zone the

- water-jet arrangement persists but seems to become trabecular. The thickenings of the tabulae are fibrous. These microstructural features indicate a high degree of evolution for some branching Permo-Carboniferous Tabulata including Thamnoporella and Gertholites.

82170 <ABSTRACT>Etude d'une faune nouvelle de Tabulés (par Y.
Plusquellec), Trilobites, Crinoïdes et Tentaculites. * Plusieurs genres
et espèces de Pleurodictyformes sont décrits dans ce travail:
Cleistodictyum porosum Plusquellec, Pleurodictyum microspinosum n.sp.,
Pl. latum n.sp., Pl. sp. A., Pl. sp. B., Petridictyum petrii (Maurer)?,
ainsi qu'une forme proche de Procteria, présentant des caractères
morphologiques très particuliers. * Le matériel à l'état de
moulage naturel, très finement conservé, a permis une étude précise de l'
ornementation des fonds calicinaux. Une abondante représentation
en est donnée. L'auteur a tenté de représenter également, à l'aide de figures
conventionnelles la morphologie de ces fonds
calicinaux. * Chez Cleistodictyum porosum, l'étude du mode de
croissance de la colonie a conduit à proposer quelques termes nouveaux
pour repérer les différentes corallites. * Compte tenu du mode de
conservation du matériel, aucune donnée sur la microstructure n'est
est disponible.</ABSTRACT>

crossing?</TITLE>
82195 <SOURCE>FC&P 14, 2: 26-27.</SOURCE>
82196 <ABSTRACT>At first sight the tabulate corals show a relatively simple
morphology. But on the other hand the radiation and the genetically
fixed changes can be recognized by detailed analysis of
microarchitectural or microstructural features, as well as by the
evaluation of variability pattern. The complete description is usually
based on total quantified features (dimensions etc.) and on qualitative
series coded into quantitative form (microstructure etc.). Ecological
interactions, provide another useful criterions. For the description of
each tabulate colony about 110 alternative characters or about 25
multistage characters are distinguished in our laboratory. [first part

- 82234 <SOURCE>FC&P 06, 1: 15-16.</SOURCE>
- 82235 <ABSTRACT>Une révolution a été introduite dans l'étude des organismes constructeurs par la découverte dans les mers actuelles de Spongiaires à test hypercalcifié parfois facultatif (Merlia) et qui peuvent être dépourvus de spicules. Nous avons décidé de reprendre en détail la recherche de critères permettant d'en distinguer ou d'en rapprocher certains groupes constructeurs de position systématique mal établie, par exemple les Trépostomes (rangés parmi les Ectoproctes Sténolèmes, Termier et Termier 1976) et les Tabulés (rangés dans les Cnidaires). Nous pensons devoir classer auprès des Chaetetoïdes non seulement plusieurs Favositina à éléments de petites dimensions tels que Staphylopora Le Maître 1956, Riphaeolites Yanet in Sokolov 1955 (pourvu de cf. astrorhizes = rhodorhizes) mais aussi des formes plus classiques à calices plus grands telles que Favosites aenigmaticum Porfiriyev 1937 qui semble posséder des orthotriaenes. Les Thécidiés, avec Thecia Milne-Edwards et Haime 1849, paraissent devoir être apportés au même ensemble. La texture fibreuse du test est chaetetoïde. La présence de pores permettant le passage des fluides entre les tubes cloisonnés est comparable aux prosopyles reliant entre eux les tubes radiaires du sycon par exemple. * Les tubes de Syringoporacea ont une disposition semblable à celle des astrotubes de Stromatopores de type Trupetostroma par exemple. Cette assimilation pourrait expliquer la facilité de la symbiose dite Caunopora entre les deux groupes. La présence de planchers ou de plaquettes entre les tubes de certains Syringoporacés indique d'ailleurs l'existence de tissus vivants extracalicinaux, les calices pouvant alors avoir eu un rôle atrial. Les baguettes calcitiques (épines) traversant le test fibro-lamellaire des Syringoporidés, des Grabaulitidés (Auloporida p.p. de Stasińska), de certains Favositidés et des Pleurodictyidés (Procteria et certains Michelinia) suggèrent encore, chez ces Tabulés, une sorte de sécrétion apparentée à celle des spicules des Spongiaires. 82312 <SOURCE>Palaeontology 30, 3: 485-492.</SOURCE>
82313 <ABSTRACT>Although the favositids have been traditionally interpreted as a group of Palaeozoic tabulate corals, there has been persistent speculation, particularly over the last decade, that they could be the massive basal skeletons of sponges and should be transferred to the Porifera. Two recent papers, claiming respectively the preservation of spicules and the fossilization of soft polyps, strongly focus the dispute. Here, all the evidence relating to the affinities of the favositids, including these recent claims, is reviewed. It is concluded that this evidence strongly favors retention of the favositids within the Tabulata and assignment of the Tabulata to the Cnidaria Anthozoa.</ABSTRACT>

82324 <TITLE>Evaluation of corallite size as a criterion for species discrimination in favositids.</TITLE>
82325 <SOURCE>Journal of Paleontology 62, 1: 32-40.</SOURCE>
82326 <ABSTRACT>Of all the morphologic characters used in favositid taxonomy, corallite size has most frequently been given more weight than others because of its relative ease of measurement and because it has been generally believed to be less variable. This study evaluates the reliability of corallite size as a criterion by a statistical treatment of several populations of favositids in the Upper Silurian west Point Reef Complex in Gaspé, Quebec. Calculation of corallite cross-sectional area was made feasible by computer-based image analysis which provides a quick and accurate measure of size. The present study shows that the mean of the largest 10 percent corallite areas in mature parts of colonies with a minimum sample size of 100 corallites per cross section is the best approximation available of mean adult corallite size. It is suggested that intraspecific variability of corallite size is often too large for this character to be used in practice, probably due to phenotypic plasticity. The same may be true of most other morphologic characters. In some cases, however, one or two characters remain in variate within a species and can be used diagnostically. The same characters may be extremely variable in other species.</ABSTRACT>

82337 <TITLE>Q-Mode Cluster Analysis of Genus Favosites.</TITLE>
82338 <SOURCE>Acta Palaeontologica Sinica 27, 4: 498-513.</SOURCE>
82339 <ABSTRACT>Since tabulatormorph corals have been studied for more than a hundred years, the related scholars have laid a good foundation for their classification. Now it is essentially clear about the classification above the genus level, but, there are still some problems about the classification below the genus level, especially the species. The obvious difficulty lies in the distinction of species with too little difference and in the large number of synonyms, which cause some confusions in classification. For instance, two specimens might have been identified as different species or subspecies only because of the very little difference between their individual sizes. Thus, there would be an overflow of species names and it would become more and more difficult to master and apply the criterion for species identification.</ABSTRACT>

82350 <TITLE>Further evidence for Poriferan Affinities of Favositids.</TITLE>
82351 <SOURCE>In: Reitner J. & Keupp H. (eds): Fossil and Recent Sponges: 212-223; Springer.</SOURCE>
82352 <ABSTRACT>The new findings of spicule-bearing specimens of typical favositids confirm previous suggestions of a sponge (sclerosponge) nature of these common Palaeozoic fossils. Similar to the calcareous skeletons of other modern and fossil sclerosponges (coralline sponges), favositid fossils are basally excreted hard parts of various demosponges and, as such carry little information about the biological organization of the organisms producing them. The kinds of spicules occurring in favositids, though generally monaxonid in character, indicate that the forms assigned to Paleofavosites and Favosites, which have ophirhabds and ?heloclones, are related to choristid and/or sublithistid demosponges, whereas those assigned to Mesofavosites, enclosing fusiform oxeads in their calcareous skeleton, are related to monactinellid or ceractinellid demosponges. Further examination of favositids is needed before new taxonomy of this enormously splintered group can be established, which will take into account its poriferan affiliation. Nevertheless, terms such as "corallum", "corallites", "colony", "coenosteum", and others stemming from the long-accepted cnidarian attribution of the favositids should be abandoned. The poriferan affinity of favositids requires also a considerable reevaluation of their paleoecology, particularly concerning the role they played in ancient communities.</ABSTRACT>

82363 <TITLE>Sclerite-bearing alveolitid favositids from the Devonian of central Poland.</TITLE>
82364 <SOURCE>Paläontologische Zeitschrift 67, 1-2: 27-44.</SOURCE>
82365 <ABSTRACT>Calcitic and pyritic pseudomorphs of originally siliceous monaxonic sclerites (predominantly heloclone-like monocrepid desmas) have been found entrapped within calcareous skeletons of alveolitid favositids identified as Squameoalveolites fornicatus (Schlueter 1889) derived from Lower and Middle Devonian (Emsian and Eifelian) deposits of central Poland. The sclerites are arranged in a system of subvertical tracts forming a loose palisade along the midwall of skeletal tubes. Poorly preserved remnants of such palisades correspond to the so-called "median line" or "median suture" of typical favositids. The finding supports the hypothesis of poriferan affinity of favositid Tabulates and indicates that these common Palaeozoic fossil cannot be longer classified as Cnidaria. They should, on the basis of the sclerites, be regarded as remnants of monaxial and / or sublithistid demosponges, which - like the members of modern and fossil demosponges called sclerosponges or coralline sponges - had the ability to produce a basally secreted calcareous skeleton in addition to siliceous sclerites.</ABSTRACT>

82377 <SOURCE>Acta Palaeontologica Polonica 39, 3: 233-245.</SOURCE>
82378 <ABSTRACT>Reported are findings of calcitic pseudomorphs of monaxonic sclerites (heloclones and ophirhabds) occurring as highly ordered vertical tracts and subhorizontal strands in the midwall of calcareous skeletal tubes of a common Silurian favositid species, Favosites hisingeri, from Gotland. The discovery ends conclusively the current controversy about the nature of favositids and related tabulomorphs in favour of the neglected early suggestion of Kirkpatrick (1911) that these fossils can be basal calcareous secretions of siliceous sponges similar to those in living Merlia normani. The type of sclerites found in F. hisingeri and other favositids indicate that favositids are closely related to fossil and extant sponges classified within the order Lithistida (class Demospongia) as the so-called sublithistids.</ABSTRACT>

82389 <TITLE>Zur Kenntnis von Asterosalpinx Sokolov und anderer Sternstrukturen bei Favositinae (Tabulata).</TITLE>

- 82390 <SOURCE>Paläontologische Zeitschrift 47, 1-2: 54-68.</SOURCE>
- 82391 <ABSTRACT>Starlike structures situated in the corners of the corallites of Favosites are known from the Upper Silurian to Lower-Middle Devonian. They have been described from Europe, Asia, and Australia, by Etheridge, Frech, Tchernychev and others. Sokolov (1948, 1962) has named these structures Asterosalpinx, Antherosalpinx, and Actinosalpinx. He was [of] the opinion that they are tubes and commensales (Serpulidae) of Favosites. * The study of a specimen from the Devonian of Karaburun (Anatolia) under both light microscope and scanning electron microscope made it clear that Asterosalpinx cannot be a tube. It is a node-like structure with a microstructure consisting of two layers: a dark middle zone built up of homogenous calcite, probably diagenetic, and a peripheral zone consisting of normal fibrous calcite. These nodes are primary trabecular structures built in the corners of Favosites-like Tabulate corals. It seems necessary to erect a separate Tabulate genus for forms exhibiting this feature. Therefore, Porfireus (1937) genus Asteriophyllum should be reinstated.</ABSTRACT>

- 82417 <ABSTRACT>A long study about the soft parts, the morphogenesis of the skeleton (wall, pores, septal formations and the tabulae) and histology. Numerous microstructures which cannot be accounted for morphogenetically, found in the Tabulata and also in other fossils of the Madreporaria, are dealt with in a chapter devoted to secondary structures. These structural units which have been described especially in more recent writings have no taxonomic importance. They owe their origin to secondary, postmortal processes occurring during fossilization.</ABSTRACT>

82441 <TITLE>Revision ans Typisierung des Genus Paleofavosites Twenhofel 1914.</TITLE>
82442 <SOURCE>Paläontologische Zeitschrift 50, 3-4: 151-192.</SOURCE>
82443 <ABSTRACT>Favosites asper d'Orbigny 1850 (described by Lonsdale 1839 as a minor variety of Favosites alveolaris Goldfuss) was assigned to the genus Paleofavosites Twenhofel as type species. Misinterpretations and lack of knowledge about the type specimen always led to an erroneous synonymity with Paleofavosites alveolaris (Goldfuss 1829). The present revision is intended as a correct typisation and a new description of the holotype of the type species. In this connection Paleofavosites alveolaris (Goldfuss) and the major variety named by Lonsdale and until now in synonymity with Paleofavosites alveolaris are described, and as a result of this revision, the latter has to be placed to Paleofavosites rugosus Sokolov 1951. 82454 <TITLE>On the solenid growth habit of Paleofavosites.</TITLE>
82455 <SOURCE>Geologie en Mijnbouw 55, 3/4: 163-174.</SOURCE>
82456 <ABSTRACT>The formation of the so called "solenia", which gives the colonies- of Multisolenia Fritz 1937 the peculiar and striking appearance, is considered to be the same as that of normal pores in favositoid corals. The solenia occur in species of Multisolenia and related genera as well as in Paleofavosites Twenhofel 1914, observed for example in the type specimen of type species P. asper, e.g. in paleofavositoid forms with corallites possessing only small diameters (less than 1mm). These small measurements cause an adjoining of four corallites - instead of normally three, where the diameters reach more than 1mm - and, based on that arrangement, a crosswise, dumbbell-like connection of neighbouring individuals by pores situated in the corallite corners. Therefore the authors are of the opinion that Multisolenia and the related genera are junior synonyms of Paleofavosites. [taken from FC&P 5, 1: 34]</ABSTRACT>

82467 <TITLE>Palaeofavosites Twenhofel in place of Calamopora Goldfuss and the spelling of Palaeofavosites.</TITLE>
82468 <SOURCE>FC&P 06, 1: 13-14.</SOURCE>
82469 <ABSTRACT>The decision to the proposal forwarded by Oekentorp (1971, 1974) on "Palaeofavosites Twenhofel 1914 (Anthozoa, Tabulata): proposed validation under the Plenary Powers" has, in the meantime, been published by the International Commission on Zoological Nomenclature in Opinion 1059. According to this, the generic name Calamopora Goldfuss 1829, has been abandoned in favour of Palaeofavosites Twenhofel 1914, and listed on the Official Index of Rejected and Invalid Generic Names in Zoology (under No. 2073). Palaeofavosites was included in the Official List of Generic Names in Zoology (under No. 2028) as well as relating names of species asper and alveolaris (No. 2576 and 2577 respectively). * Though in this approval, the generic name Palaeofavosites was used in the latinized writing and not in the original writing as given by Twenhofel as Paleofavosites (see Caramanica 1975). The original citation in question could not be traced at the time of publication. The writing introduced by me in this approval was furthermore based on the - correct - latinized form generally common in literature as e.g. Lang, Smith & Thomas (1940), Sokolov (1955), Hill & Stumm (1956) and Sokolov (1962) or Flügel (1970). According to the IRZN, however, this was an unjustified emendation (article 33, see also article 32 a (ii)). In accordance to this the correct mode of writing Paleofavosites was to be continued (see Oekentorp 1976). But according to Opinion 1059, Palaeofavosites is firmly established again - based on sequently unfortunate errors. Therefore, and to avoid any further confusion and also considering the correctly latinized form of writing, it is recommended that this writing should remain as Palaeofavosites. 82480 <TITLE>Ein Spongienmodell fuer die Favositidae.</TITLE>
82481 <SOURCE>Lethaia 9: 405-419.</SOURCE>
82482 <ABSTRACT>The opinion that the Favositidae are a group of the Madreporaria is based on a paper by Edwards & Haime 1849. These authors mentioned no reason for their assumption. A critical review of the skeletal material, microstructure and morphology shows that it is difficult to compare this group with the true Madreporaria. On the other hand, the discovery of the Sclerospongiae has shown that they are recent organisms which are similar in their material and morphology to the Favositidae. The only difference is the occurrence of wall pores in the Favositidae and of astrorhizae in the Sclerospongiae. Like the primary wall grooves of the upper edge of the walls of the Favositidae, which are the primary stadium of the pores, the astrorhizae are initial grooves on the surface of the Sclerospongiae. Therefore the formation of the pores and of the astrorhizae is similar. If the Favositidae are interpreted as Porifera, the wall grooves would analogically be the impression of excurrent canals of the soft part on the surface of the skeleton. The main difficulty in an interpretation of the Favositidae as a new subphylum of the Porifera is that we are not yet informed about the formation of the basal skeleton of the Sclerospongiae.

82520 <SOURCE>FC&P 15, 1.2: 19-21.</SOURCE>
82521 <ABSTRACT>In the last issue of Fossil Cnidaria, Oekentorp and Stel (1985) drew attention to Copper's (1985) important paper on " fossilized polyps". In my opinion, they correctly emphasized the importance of Copper's work while expressing some reluctance to accept Copper's conclusions without further analysis. I would disagree, however, with the Oekentorp and Stel assumption that prior to Copper's work most Paleozoic coral workers had adopted the sponge model of favositid relationships. I think instead that, with the stimulus of the rediscovery of living sclerosponges, many students of corals have had to reconsider some fundamental questions; and, in the excitement of the moment, there have been more papers analyzing possible sponge relationships than renewing arguments for coral or cnidarian affinities. This is appropriate to the time and indicates the fundamental importance of the question, but it does not suggest that a new consensus had been achieved. [introductory remarks]</ABSTRACT>

82547 <ABSTRACT>The next three papers concern palaeobiogeographical aspects of the Devonian in Siberia and are especially based on Tabulate corals - but also on Rugose corals - listed in a tabular form and on additional maps. The following results can be given: Distribution of the Devonian corals in the Siberian seas and contiguous realms was conditioned by palaeogeographic environments. During the early Devonian there were large geographical barriers between the seas of the Altai-Sayan, Indigiro-Kolymian, and Mongolo-Okhotsk provinces that made an exchange of coral species of adjacent seas difficult. These conditioned sharp geographical differentiation of the faunas. In the Indigiro-Kolymian province the Tabulate fauna was rather uniform. Favositids predominated, e.g. above all, the Favosites socialis group. Alveolitids, and later on Striatopora, Gracilopora, etc. were abundant as well as Sqaumeofavosites etc. On the other hand, Pleurodictyum is the characteristic genus in the Mongolo-okhotian province but also species of Favosites different from those of the former province. Same facts are noted for the Rugose corals: Taimyrophyllum characterizes the Indigiro-Kolymian province, whereas Lindstroemia is a representative of the Mongolo-Okhotian area. In the Middle Devonian, boundaries of the provinces became obliterate. It resulted in the fact that the constant content of fauna in different basins was more uniform. Faunal integration continued up to the end of the Frasnian.</ABSTRACT>

Coral Reefs, Paris 1975].</SOURCE>
- 82560 <ABSTRACT>Two types of walls in Halysites are observed: an exterior and
an intercorallite wall, both of which show a different structure,
fibronormal resp. trabecular. The trabecular nature of the
intercorallite walls is to be seen as a similarity with comparable
structures in Heliolites. And - concerning the mode of secretion of the
skeleton - in both, Halysites and Heliolites. this is entirely secreted
by the basal ectoderm of the polyps and the coenosarc. Moreover,
analogous coenosteal structures, for instance in Propora and
Cystihalysites, Heliolites and Halysites, led to question the close
relationship of these two different groups but which evolve
independently and apart of the Tabulata.</ABSTRACT>

82597 <TITLE>Colony development and formation in halysitid corals.</TITLE>
82598 <SOURCE>Lethaia 23: 179-193.</SOURCE>
82599 <ABSTRACT>Modes of colony formation and their relationship with colony morphology, size and substrate characteristics in species of halysitid corals have been studied. Two distinctive modes of colony formation in halysitids are proposed. In the monoplanulate mode, represented by *Catenipora simplex*, the colony is developed from a single protocorallite and colony formation is achieved by a combination of asexual increase and intracolony fusions. In contrast, the polyplanulate mode is demonstrated by *C. escharoides*, in which the early colony formation is achieved primarily by fusions of many " incipient colonies" of more than a single planulate origin and of different generations. The latter mode has not previously been described in tabulates and has significant implications for coloniality, reproductive and life history characteristics, histo-compatibility and adaptative ecology. The colony size and morphology, and the distribution of halysitid species were primarily determined by the modes of colony formation and the substrate characteristics. Colonies of the monoplanulate mode, when developed on soft substrates, exhibit a small and spherical morphology with isolated distribution patterns, while those developed on hard substrates are tabular and variable in size, depending on the availability of substrate. In colonies of the polyplanulate mode, on the other hand, the size of the colony is largely dependent on the frequency and timing of allograft fusion. They are characteristically found on soft substrates, often as dense monospecific thickets. The mode of colony formation in halysitids is probably species-specific and results in the adaption to substrates.</ABSTRACT>

82611 <SOURCE>Acta Palaeontologica Polonica 43, 4: 635-651.</SOURCE>
82612 <ABSTRACT>The question of whether branching and budding in halysitid tabulate corals was regulated by the availability of nutrients or exposure to waste products is important for taxonomy. Moreover, such regulation could have implications for paleoenvironmental interpretation. Although the statistical and morphological evidence presented here is not unequivocal, it is suggested as a working hypothesis that halysitid astogeny was indeed regulated. This would be in accordance with current theories on the growth of recent corals and sponges. The simulation results are used to reevaluate functional advantages of the regulation of the halysitid colony.</ABSTRACT>

82651 <ABSTRACT>On account of a critical reflection on monographical
literature as well as personal observations, it is concluded that the
Halysitida is a polyphyletical order, as the chain-like hereditary
factors appear in different corals. The halysitoid shape of the
corallum only represents a polymorphic modification of spatial
arrangement of the corallites and, therefore, does not prove a
hereditary relationship between taxons. It is proposed to abandon the
order Halysitida, to place the genera Halysites, Cystihalysites,
Spuamaeolites and Hexismia into the subclass Heliolitoidea and to
connect the genera Catenipora, Vacuopora, Tollina and Eocatenipora to
the order Lichenariida (subclass Tabulata).</ABSTRACT>

's "spicules" in Quepora ? agglomeratiformis (Whitefield).
</TITLE>
82676 <SOURCE>FC&P 18, 2: 22-25.</SOURCE>
82677 <ABSTRACT>The badly preserved "spicules" within one single
specimen of the halysitid Quepora are very doubtful and can better be
interpreted as traces of microborings! Not all longitudinal, pyritic
structures within tabulates and other problematic benthic organisms,
e.g. stromatoporoids, are spicules. Arrangements and spicule types must
be carefully analysed and compared with other similar structures, like
borings. These features are a trap! * Nevertheless, microborings in an
Ordovician shallow marine benthic organism are important and should be
carefully described. * The question if halysitid tabulates are
cnidarians or sponges, cannot answered by this particular specimen
[described by Kazmierczak, 1989; concludes Reitner].</ABSTRACT>

82701 <TITLE>Organisation de type tetracoralliaire des rides septales de
Palaeacis (Cnidaria, Carbonifere).</TITLE>
82702 <SOURCE>Lethaia 23: 385-397.</SOURCE>
82703 <ABSTRACT>The tetracoral pattern of septal ridges described in
Kerfordedictyum (Devonian Pleurodictyum-like coral) is scarce in the
Tabulata, but has been found in Palaeacis sp. from the Visean of
Algeria and in P. cuneiformis subsp. A from the Visean of Australia.
Palaeacis sp. shows a strong cardinal septal ridge in peripheral
position, just opposite the counter ridge, thus creating a plane of
bilateral symmetry; an area on both sides, which is always blurred,
indicates the position of the alar ridges. Counter-lateral ridges are
not easily identified and yield differing interpretation. Compared with
the Rugosa this area presents distinctive features. In P. cuneiformis

subsp. A, transverse section exhibits four well-developed septal ridges than coalesce in the axis of the corallite with obvious bilateral symmetry. The systematic position of the genus *Palaeacis* is questioned: *Rugosa* it is not; it may belong to *Tabulata*; however, erecting a new higher taxon for *Palaeacis*, *Trachypsammia* and other *Pleurodictyum*-like corals is premature at our present state of knowledge.</ABSTRACT>

82805 <TITLE>An approach to automatic identification of tabulatormorphic corals.</TITLE>
82806 <SOURCE>Acta Palaeontologica Sinica 34, 1: 119-127.</SOURCE>
82807 <ABSTRACT>The automatic identification of tabulatormorphic corals is realized by the following steps. First of all, hundreds of retrieval tables of the fossil-identification features of each taxonomic unit from the genus above are created, on the basis of the currently published 3 superorders, 10 orders, 15 suborders, 85 families, 15 subfamilies, and 476 genera of the subclass Tabulatomorpha in the world and 2 225 species found in China. Secondly, after the coding of the identification features, these tables are stored under a tree structure database system by applying dBASE-II, with each table corresponding to a database. Finally, according to the systematic taxonomy of tabulatormorphic corals, the automatic identification of an unknown specimen is progressively proceeded from a higher taxonomic unit to a lower unit until species. If the unit is from the genus above, the degree of membership is determined after the weighing of the features, with the highest degree indicating the belongingness of the unknown specimen to a specific unit. On the other hand, in case the unit is the species, a similarity coefficient is used to measure the similarity of an unknown specimen to each species of a specific genus based on the numerical taxonomy of the already known specimens of the genus, which redefines the species of the genus through scaling the features, weighing the features, determining the similarity coefficient between every two of the known specimens, and cluster analysis of all the known specimens. The best coefficient shows the species decision of the unknown specimen. An identification example is given in this paper, with very satisfying result.</ABSTRACT>

82818 <TITLE>Ultra-microskeletal Structures, Classification, Evolution and its Use in Taxonomy of Tabulatomorph Corals.</TITLE>
82819 <SOURCE>Geological Publishing House, Beijing: 125 pp., 56 pls, 34 textfigs.</SOURCE>
82820 <ABSTRACT>The present monograph is based on the examination of 101 genera of tabulatomorph corals (79 genera of Tabulata, 15 genera of Heliolitoidea and 7 genera of Chaetetoidea). Data on skeletal microstructure were obtained from thin sections and SEM observation. SEM photographs were all made from lightly acetic acid-etched surfaces. Microskeletal structures of Tabulatomorph corals, investigated by SEM, revealed three fundamental kinds: 1, the crystal granules, with calcite granules; 2, the crystal flakes, with calcite flakes and slabs and 3, the crystal fibrous, with brachycolumns and needles. The three kinds of fundamental units combined with each other in various ways to form seventeen types (or patterns) of micro structure such as: 1, the granular type; 2, the double-comb type; 3, the com type; 4, the hemi-pinnate type; 5, the pinnate type; 6, the fan-like type; 7, the fibro-lamellar type; 8, the paratrabecular type; 9, the trabecular type; 10, the rhabdotrabecular type; n, the eotrabecular type; 12, the parallel lamellar type; 13, the plicated lamellar type; 14, the

V-shaped type; 15, the A-shaped type; 16, the Y-shaped type and 17, the zigzag type. The first type belongs to the crystal granular kind; the second to the 12th ones belong to the fibrous kind and the 13th to the 17th ones belong to the crystal flake kind. The crystal granular kind of fundamental units of microstructure is the oldest one in the three fundamental ones. It developed in the oldest tabulatormorph corals such as in Lichenariida, Tetradiida and some Cambrian Auloporida. The crystal flake and the crystal fibrous kinds are the younger ones. It were very common in Upper Ordovician to Mesozoic tabulatormorph corals. The use of microstructure in taxonomic studies of tabulatormorph corals are very important. The different fundamental kinds are as the specific character of Superorders, Orders, and the different microstructural types (or patterns) to characterize families, genera have been quite successful. This book is intended for palaeontologists, Geologists and stratigraphers.

82831 <TITLE>The microcomputer processing system for the identification of Tabulatormorphic corals genera - species.</TITLE>

82832 <SOURCE>Geological Memoirs 2, 16; vi + 140 pp. [in Chinese, with English abstract]</SOURCE>

82833 <ABSTRACT>with the rapid development and extensive application of computer science, it is high time to introduce advanced microcomputer technology into the field of paleontology. Automatic processing of paleontology data with microcomputer is a kind of vanguard which paves the way for vigorous development of paleontology. It plays a particularly important role in automatic identification of fossils. The key to microcomputer automatic processing of paleontology data lies with integration of traditional processing methods and computer technology. The book, based on the currently published 3 superorders, 10 orders, 15 suborders, 85 families, 15 subfamilies, and 476 genera of the subclass Tabulatormorpha in the world and 2225 species found in China, explores the way to the realization of computerized processing of fossil Tabulatormorphic Corals, its process and mathematical models. 82844 <TITLE>Ontogenies and astogenies and their significance in some favositid and heliolitid corals.</TITLE>

82845 <SOURCE>Journal of Paleontology 64: 515-523.</SOURCE>

82846 <ABSTRACT>The level of colony integration in tabulate corals is the degree of colony unity with respect to behavior, physiology, and development of individual organs or organ complexes within colonies. These are difficult to assess in fossils, but the level of colony integration can be tested by analyzing ontogenies and astogenies of two common Paleozoic tabulate coral groups, favositids and heliolitids.

Favositids have been previously interpreted as highly integrated colonies, but results of the present examination suggest that the level of colony integration in favositids was rather lower than hitherto assumed. The ontogenies and astogenies in favositid colonies are not correlatable; thus, the significance of ontogenetic and astogenetic variations for systematic and phylogenetic resolution in favositids is difficult to assess at present. In contrast, astogenetic developmental sequences are recognized in heliolitids. Ontogenies in heliolitids were subordinated to the astogeny of the colony. This is closely related to the high degree of colony integration with respect to behavior and physiology of individual organs or organ complexes within colonies. Individual corallites were well linked and coordinated so that the whole colony could have functioned as a single individual. As a result, evolution in heliolitids operated at the colony level and by heterochronic (and other) modifications of astogenies rather than of ontogenies.</ABSTRACT>

82872 <ABSTRACT>Measurements of corallite size and spacing are useful as species discriminators and as indicators of variability in tabulate corals, but it must be recognized that these characters are affected by corallite packing in massive colonies. A new, practical method for corallite size measurement in favositids is based on an aspect of their packing: polygonality. Corallites with six and more sides are considered to be adults. They have virtually normal size-frequency distributions on both dimetric and non-dimetric transverse sections, making possible the use of basic statistics. The method has been found to work consistently for many species, regardless of corallite size or colony form. Comparisons between favositids and heliolitids indicate that corallite size distribution is related to packing and rates of offsetting. Differences in size distribution between favositids and most heliolitids are due to colony design; rates of corallite and tabularium expansion were constrained by physical packing. The heliolitid coenenchyme permitted a greater flexibility of growth strategy than the contiguous corallites of favositids.</ABSTRACT>

82909 <TITLE>Les genres Utaratuia, Tabellaephyllum, Michelinia et la distinction Tabulata-Rugosa.</TITLE>
82910 <SOURCE>Annales de Paléontologie (Vert.-Invert.) 76, 1: 13-39.</SOURCE>
82911 <ABSTRACT>The genera Utaratuia (Rugosa), Tabellaephyllum (Rugosa or Tabulata ?) and Michelinia pro parte (Tabulata) form a set linked by synonymy. * Revision of the holotype of Utaratuia laevigata Crickmay 1960 from the Hume Formation, early Givetian, Northwest Territories, Canada, allows to establish the microlamellar constitution of the wall, to confirm the fibrous constitution of the septal ridges and their non trabecular structure. * The holotype of Tabellaephyllum peculiaris Stumm 1948, possibly from the Escabrosa Limestone, Lower Mississippian of SE Arizona, is a completely silicified specimen and its microstructure remains unknown; mural pores on the centers of the faces and at the angle between faces are described. * A comparative and preliminary study of Michelinia expansa White 1883 from the type area (Chouteau limestone, Sedalia, Missouri, Lower Mississippian) and from the Western Interior Province (Redwall Limestone, Arizona Lower Mississippian) shows that they seem to belong to two different species.

* The specimens from Missouri are completely silicified and their precise generic attribution is impossible. Those of the WIP are sometimes well preserved, the microstructure of the wall is microlamellar and they are to be assigned to *Tumacipora* Lafuste & Plusquellec 1985. A comparison of the different features of the *Tabulata* and *Rugosa* shows that a lot of features are common and that only the true mural pores do not exist in the *Rugosa*. The following systematic attributions are proposed: *Utaratuia* is a *Rugosa* for the same reason as pointed out by Jell and Hill, *Tabellaephyllum peculiaris* is a michelinimorph *Tabulata* probably to be assigned to the genus *Tumacipora* but to the species *expansa*. </ABSTRACT>

82922 <TITLE>Origins and relationships of Paleozoic coral groups and the origin of the Scleractinia.</TITLE>

82923 <SOURCE>Paleontological Society Papers 1 [Stanley G. D. jr (ed.): Paleobiology and Biology of Corals]: 107-134.</SOURCE>

82924 <ABSTRACT>Two major groups of corals have essentially continuous records from the Early Ordovician (*Tabulata*) and Middle Ordovician (*Rugosa*) to the end of the Permian. A third major group, the living Scleractinia, range from Middle Triassic to Holocene. Additional groups have shorter ranges within the Paleozoic. The origins and relationships of these groups have been discussed for over 100 years. Relations between the *Rugosa* and Scleractinia have attracted the greatest interest because of their morphologic similarities and the time sequence. Arguments involve the significance of serial versus cyclic septal insertion, calcitic versus aragonitic skeletal mineralogy, and the time gap between the last rugosans and first scleractinians (there are no known Lower Triassic corals). Discussions of relationships among the various Paleozoic groups are commonly based on detailed morphological comparisons because of their overlapping stratigraphic ranges. Recent work on the living corals and anemones supports a closer relationship between groups than is suggested by placing them in different orders or suborders. The paleontological record of " anemones" is slight, but it is reasonable to assume that one or more groups of skeletonless zoantharians persisted through long parts of the Phanerozoic. It is suggested that the major groups of zoantharian corals originated through the development of skeletons in various anemone groups at several different times.</ABSTRACT>

82935 <TITLE>The coral skeleton: analogy and comparisons, Scleractinia, Rugosa and Tabulata.</TITLE>

82936 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 063-070. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>

- 82937 <ABSTRACT>The analogy between modern scleractinian corals and Paleozoic rugose and tabulate corals can add to understanding of their skeletal structures and method of formation. It is based on similarities in overall morphology of corallites, polyps, and in the supposed formation of exoskeleton by polypal ectoderm utilizing organic matrix in all three groups. Skeletal structures in Paleozoic corals and scleractinians suggest that a similar model for biocrystallization is applicable for major portions of both groups. The scleractinian coral skeleton is characterized by combinations of trabecular and fibrous structures only. As there is no major variation in these two basic skeletal structures in the Order Scleractinia, such variation is not expected at the genus or species level in Paleozoic corals. A general model for biocrystallization in most Rugosa and Tabulata can resemble that for the scleractinians in all essential ways except mineralogy. The origin of lamellar skeletal structures remains an enigma, as it is not explained by this model for skeletogenesis. Mineralogy of Paleozoic corals was calcitic, with a postulated MgCO₃ content of 5 to 8 mol percent.</ABSTRACT>

83052 <TITLE>The origin of Metazoa and the main evolutionary lineages of the animal kingdom: The Gallertoid hypothesis in the light of modern research.</TITLE>
83053 <SOURCE>Senckenbergiana lethaea 82, 1: 295-314.</SOURCE>
83054 <ABSTRACT>A scenario for the evolutionary history of the Metazoa is presented, including the evolution of the Urmetazoa and the Ctenophora, Porifera, Coelenterata, and early Bilateralia. The reasoning about evolutionary transformations is based on engineering morphology, and includes the results of comparative anatomy and of molecular research. According to their evolutionary model, the specific metazoan multicellularity, which is different of that of fungi and plants, evolved in multinucleate heterotroph unicellular organisms by the deposit of gelatinous / fibrous substance into the endoplasmatic reticulum. The multitude of cells, the syncytia, and the extracellular matrix with gelatinous properties and containing collagenous fibers, developed dependent of each other and simultaneously. The resulting ancestral metazoan, the ur-metazoan, was named 'gallertoid'; (German: Gallerte = gelatine) for the main feature of its body support, viz. the gelatinous / fibrous material. By further internal differentiation of gallertoids several evolutionary lineages developed independently: Trichoplax, the Ctenophora, the Porifera, the Coelenterata, and the Bilateralia (= Coelomata), which soon split into two lines, the Notoneuralia and the Gastroneuralia. [original summary]

- 83065 <TITLE>Les bioconstructions à Rudistes: paléocéologie, paléogéographie, sédimentologie.</TITLE>
- 83066 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 21.1-21.12.</SOURCE>
- 83067 <ABSTRACT>Ce cours est consacré aux bioconstructions à rudistes. Il nous a semblé nécessaire d'aborder cette question d'une manière aussi complète que possible. C'est ainsi que nous traiterons de problèmes variés touchant à la paléobiologie, la paléocéologie, la sédimentologie, la paléogéographie des bioconstructions à Rudistes et des formations qui leur sont associées. * Le cours est divisé en trois parties. La première traite des rudistes, de leur classification et de leur paléocéologie; nous insisterons tout particulièrement sur les rudistes bioconstructeurs. La deuxième partie aborde la question des bioconstructions à rudistes aussi bien dans leur aspects paléocéologique que morphologique ou textural. La troisième partie, enfin, est consacrée aux formations à rudistes; elle est illustrée par l'étude de quelques modèles qui ont fait l'objet des recherches de l'auteur ou de ses élèves. 83117 <TITLE>Die Evolution der Coelenterata. II. Solitare und koloniale Polypen.</TITLE>
83118 <SOURCE>Natur und Museum 128, 10: 329-341.</SOURCE>
83119 <ABSTRACT>All anthozoan types apart of the octocorallia are basically solitary polyps, some secondarily developing polyp colonies; in all the inner gelatinous-fibrous mass is largely reduced, forming a thin layer; the body motility is high, and no internal skeletons are formed; rigid skeletons are external productions (or, in Zoantharia, secondarily incorporated particles). For engineering reasons, the body shape of solitary polyps without (external) skeleton and of polyps with skeleton but single mesenteries is restricted to a cylindrical form; only polyps with paired mesenteries and skeleton, viz, scleractinia, are able to expand laterally during growth. Apart of the Anthozoa, the evolutionary lineage to the Tetrzoa, (the Scyphozoa, Hydrozoa, and Cubozoa), characterized by alternating polyp/medusae generations, can be explained as an offshoot of the ancestral gelatinoid coral. 83130 <TITLE>Experimental Coelenterate Biology.</TITLE>
83131 <SOURCE>Univ. of Hawaii Press, Honolulu; 282 pp.</SOURCE>
83132 <ABSTRACT>This book is stated to be "the product of a summer course in which students were trained to investigate the biology of coelenterates by using a variety of experimental procedures". Neither this statement nor the title is likely to attract the attention of paleontologists and even many neontologists may "put it off". This would be unfortunate, because there is something of interest in this book for a variety of specialists. The book consists of 25 papers in four sections - growth and development, feeding and metabolism, endosymbiosis with algae, and calcification. Hydroids were the most common subject of observation and experimentation but scleractinian corals are the immediate subject of 7 papers, and 4 more papers report broad surveys that included corals. The section on calcification begins

- with a general review paper and proceeds to papers on sources of carbon, temperature effect on rate of calcium-45 uptake, and organic matrices. These and a report on raising planulae and newly settled polyps, will be the most useful for those primarily interested in coral morphology and growth. Other papers include many observations on behavior and natural history that will inevitably make corals more understandable to those who are not actively working with the living animals. 83195 <TITLE>Class-level relationships in the phylum Cnidaria: Molecular and morphological evidence.</TITLE>
83196 <SOURCE>Molecular Biology and Evolution 12, 4: 679-689.</SOURCE>
83197 <ABSTRACT>The evolutionary history of cnidarian life cycles has been debated since the 1880s, with different hypothesis favored even by current textbooks. Contributing to the disagreement is the fact that the systematic relationships of the four cnidarian classes have received relatively little examination using modern systematic methods. Here we present analyses of class-level relationships based on 18S ribosomal DNA (rDNA) sequence, mitochondrial 16S rDNA sequence, mitochondrial genome structure, and morphological characters. DNA sequences were aligned using a repeatable parsimony-based approach incorporating a range of alignment parameters. Analyses of individual data sets and of all data combined are unanimous in grouping the classes possessing a medusa stage, leaving the holobenthic Anthozoa basal within the phylum. 83378 <SOURCE>American Scientist 79: 224-233.</SOURCE>
83379 <ABSTRACT>This review article summarizes the different kinds of sponges, their organization, the history of the discovery of coralline sponges with their aspiculate skeletons and traces their relationships to archaeocyathids, sphinctozoans, stromatoporoids, and chaetetids. An extensive historical review of opinions about the affinities of these four groups is presented. The viewpoint that the solid skeletons are a convergent feature of diverse sponge lineages and hence express a stage of evolution rather than characterizing a monophyletic taxon is endorsed. Sponge faunas of the upper Paleozoic are claimed to fill the gap between mid-Paleozoic and Mesozoic stromatoporoids. Many features of corals and sponges are convergent and should not be the basis of definitions of taxonomic groups. Only spicules are reliable for determinations of affinity and phylogeny of sponges.</ABSTRACT>

83392 <ABSTRACT>Spicules reveal a polyphyletic origin for stromatoporoids, chaetetids, and sphinctozoans within the Demospongiae and Calcareo. Calcareous skeletons have been independently acquired and are easy to secrete through a limited number of biomineralization mechanisms. The calcareous skeletons are of little value in assessing evolutionary ancestry. These groups are regarded as grades, not reflecting systematic position but determined ecologically. Archaeocyaths inhabited soft substrates in unstable conditions and were unable to construct a reef framework. They gave rise to some sphinctozoan- and stromatoporoid-grade forms. Stromatoporoids and chaetetids are modular organisms with great plasticity of growth morphology. Their encrusting growth allowed them to build mid-Paleozoic reefs. Sphinctozoans are solitary or pseudomodular, small and fragile; they were dwellers and bafflers. Corals became dominant reef-builders of the Mesozoic and Tertiary presumably due to the acquisition of more porous skeletons and their faster calcification rates aided by zooxanthellae. Modular grades of sponges may be derived from solitary ones by paedomorphosis.

83416 <TITLE>The presence of flagellar vanes in choanomeres of Porifera and their possible phylogenetic implications.</TITLE>
83417 <SOURCE>Z. zool. Evolut.-forsch. 29: 312-319.</SOURCE>
83418 <ABSTRACT>wing-shaped projections (vanes) of the flagella of

- choanomeres are documented from the hexactinellid sponge *Aphrocallistes vastus*. This observation completes the report of such flagellar structures from the major taxa of the Porifera: Demospongiae, Calcarea and Hexactinellida. It thus allows us to assume flagellar vanes being an autapomorphy of the monophylum Porifera. The wing-shaped flagellar vanes of sponge choanomeres often have been compared with appendages of choanoflagellates, e.g. *Codosiga*, but fundamental differences seem not to allow any homologization of these structures. Only extensive comparative TEM studies on well-fixed tissues, e.g. from fresh water sponges such as *Ephydatia*, will settle this question. </ABSTRACT>

83444 <ABSTRACT>The application of "IdentifyIt" from Linnaeus II to create a visual sponge identification guide is explored. A model for a field key using morphological characters with its various states represented graphically is developed. Taxonomic characters that can be easily and accurately represented and interpreted by an inexperienced user are chosen. These characters include shape, surface, oscule morphology and arrangement with a range of 3-15 character states each. A graphic representation of the skeletal characteristics and/or whole animal pictures, stored in the "Species card" mode of Linnaeus II, will allow further corroboration of the identification produced by the search from the "IdentifyIt" key. The graphic capabilities and limitations of the current Linnaeus II software to create and use a visual identification system are discussed. [original abstract]</ABSTRACT>

83456 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 27-35.</SOURCE>
83457 <ABSTRACT>When identifying a specimen, experts in systematics are able to draw sound conclusions even in the presence of uncertain and incomplete data. The purpose of this paper is to report on how expert system technologies enable us to model taxonomic expertise and simulate some of the experts' reasoning skills. We emphasise the reasoning strategies of SPONGIA, an expert system to help in the identification of marine sponges. It has been implemented using the MILORD II language for the construction of expert systems. We illustrate how the richness of taxonomic knowledge has been represented by means on rules and meta-rules. In addition, we show how the uncertainty handling and deduction mechanisms make it possible to emulate complex identification strategies such as those exhibited by experts in systematics. 83470 <ABSTRACT>A protocol is proposed by which certain classes of characters may be selected for use in phylogenetic reconstruction due to their overall better consistency in phylogenies. Alternatively, they could receive additional weight as opposed to classes that show an overall poor consistency and should be down weighted. We recognized 16 classes of characters within previously published data matrices of 17 poriferan phylogenies involving 221 OTUs (Operational Taxonomic Units, = terminal taxa). Only five classes occur in samples of large enough size that can allow discussion of observed trends. The high consistency observed in choanosomal architecture characters is possibly an artefact. Megascleres and microscleres show opposing results and these are discussed with reference to function and adaptation. In general, results are deemed preliminary because sample sizes are too small for the majority of recognized classes of characters, and different classes of characters may perform differently in different taxa, a suspicion which calls for an even larger sample base. 83481 <TITLE>Sur la representation et le traitement des connaissances descriptives: une application au domaine des eponges du genre Hyalonema.

- 83482 </TITLE>
<SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 37-48.</SOURCE>
- 83483 <ABSTRACT>Sponges of the genus Hyalonema were used as an application domain for conceiving, developing and evaluating softwares that cover a great part of the taxonomist needs: acquiring and managing descriptions, processing characters for classification purpose, building expert systems based on induction or case-based reasoning technologies for identification purpose. All these tools are relying on a new representation formalism of descriptions, which is naturally structured. The structure is elaborated by representing all what is observable in a descriptive model. The multiple interests of this methodological approach are discussed, in particular its affinity to high quality information exchanges between researchers, through networks. Some already available software tools are briefly presented. [English abstract of a paper in French]</ABSTRACT>

- 83496 <ABSTRACT>Poriferan species data storage and identification using ETI's multimedia software package Linnaeus II were tested in several regional projects (Western Europe, Central West Atlantic and Papua New Guinea). Multimedia species data storage (texts, pictures, films) and retrieval with this software program appear to be easy to use, through pull down menus, button and text clicking, and uniformly applicable through standardized formats. Identification using multiple keys and a diversity of multi-media characters may be easily customized for different user groups. Regional or taxonomic monographs are assembled on CD-ROM for cheap and easily accessible dissemination. The stored data will also be made accessible on line. [original abstract]</ABSTRACT>

- 83509 <ABSTRACT>This note discusses requirements for a knowledge medium in sponge taxonomy. Such a knowledge medium provides computer-support for the day-to-day scientific work of a group of expert-scientists, working in the field of systematics for sponges. It is also an instrument for

- the dissemination and use of the research results produced in it. The quality of such a knowledge medium depends on the extent in which it supports the daily practices of scientists working together, making abstraction of the differences in time, space and conceptual vocabulary that divides them. After a general motivation we describe a selection of functional and non-functional requirements and illustrate these with an experimental implementation based software agents on the world-wide web. 83521 <SOURCE>Natur u. Museum 122, 7: 201-210. [in German]</SOURCE>
83522 <ABSTRACT>Die stammesgeschichtliche Ableitung der Schwämme, ebenso wie der anderen "Niederen Tiere", war bis in die neueste Zeit ein ungelöstes Problem der Zoologie. Das ist nicht etwa einem Mangel an Sachkenntnissen zuzuschreiben, die durchaus reichlich sind, sondern dem mangelhaften methodischen Ansatz und der dürftigen theoretischen Zugangsweise der bis heute üblichen Stammesgeschichtsforschung: man glaubt die gewünschten Einsichten in Evolutionsabläufe dadurch zu erhalten, dass man anatomische (und auch physiologische) Gegebenheiten verschiedener Tiergruppen vergleicht und im Sinne der Homologienforschung reiht. Solche Vorgabe lässt aber jede beliebige Reihung zu und liefert somit gänzlich unverbindliche Ergebnisse. [first fragment of extensive summary]</ABSTRACT>

83548 <ABSTRACT>Teil I des Aufsatzes im Juliheft von Natur u. Museum zeigte, auf welchem Wege die Körper-Konstruktion der urtümlichen Gallertoide

entstand. Das Ergebnis ist der Schwamm als hoechst effizientes Feinfiltersystem, welches feinste Partikel, vor allem auch Bakterien, als Nahrungs-basis nutzbar macht. Der Zusammenhalt des Korpers mit seiner nur geringen Masse ruht ganzlich auf Skelettstrukturen. In sie eingebunden ist das ausgedehnte Kanalsystem mit seinen weitlumigen Einstrom- und Ausstrom-Teilen und den Engstellen, in denen der Wasser-strom angetrieben und ausgefiltert wird. Die unterschiedlichen Ausgestaltungen lassen Entwicklungslinien erkennen, die von der ursprunglich komplizierten Form hin zu Vereinfachungen fuehren.

83560 <SOURCE>Berliner geowissenschaftliche Abhandlungen E09: 183-190.</SOURCE>

83561 <ABSTRACT>The Treatise on Invertebrate Paleontology, Part E Porifera (De Laubenfels 1955) cotains unusally many nomenclatorial errors and omissions. These are misspellings, unrecognized homonyms, unjustified replacement names, unrecognized objective synonyms, wrongly designated type species, wrong autorships and publication dates etc. and others. In this publication, they are corrected or the errors are pointed out respectively. Since younger subjective synonyms possibly exist, the homonyms here found with two exceptions are not replaced by new names. Manzonina Giattini 1904 non Manzonina Brusina 1870 nec Pomel 1883 is replaced by Manzonispongia n.gen., a Tertiary hexactinellid sponge. For walcottella De Laubenfels 1955 (nom.nov. pro Rhopalicus Schrammen 1936, non Foerster 1856) which is preoccupied by walcottella Ulrich & Bassler 1931 (Crust.) we propose Keuppiella nov.gen.. Both genera keep their respective type species.</ABSTRACT>

83572 <TITLE>Sponge phylogeny, animal monophyly, and the origin of the nervous system: 18S rRNA evidence.</TITLE>

83573 <SOURCE>Canadian Journal of Zoology 74: 2031-2045.</SOURCE>

83574 <ABSTRACT>We sequenced 18S rRNA genes of a calcareous sponge, Clathrina cerebrum, a demosponge, Axinella polypoides, and a zoanthid cnidarian, Parazoanthus arinellae. Our phylogenetic analysis supports the monophyly of kingdom Animalia and confirms that choanoflagellate protozoans are their closest relatives. Sponges as a whole are monophyletic, but possibly paraphyletic; demsponges and hexactinellids form a monophyletic group of siliceous sponges. Our phylogenetic trees support a monophyletic origin of the nervous systems in the immediate common ancestor of Cnidaria and Ctenophora. They weakly suggest that animals with a nervous system may be more closely related to clacareous sponges than to siliceous sponges; the nervous system might have originated in an early calcareous sponge. Our trees confirm that

Myxozoa and Placozoa are animals that arose by secondary loss of the nervous system, but suggest that Myxozoa may be sisters of, rather than derived from, Bilateria. Kingdom Animalia is divided into four subkingdoms: Radiata (Porifera, Cnidaria, Placozoa, Ctenophora), Myxozoa, Mesozoa, and Bilateria. The 18S rRNA evolution in early Bilateria followed by normal low rates for about 500 million years.

83587 <ABSTRACT>"Sponge Sciences" is the proceedings of the International Conference on Sponge Science, held at the Lake Biwa Research Institute in March 1996. The conference was organized as a forum between meetings of the Porifera Congress, which are held every 7 or 8 years. More than 100 researchers from 15 countries participated in the International Conference on Sponge Science, the first ever convened in the Japan-Asia region. A number of reports covering various aspects of sponge studies were presented at the conference, and those reports, with subsequent discussions, represent significant achievements in the field. * The important achievements that came out of the conference have been compiled in 35 research papers in this volume of proceedings.

83598 <TITLE>Thesaurus of Sponge Morphology</TITLE>

83599 <SOURCE>Smithsonian contributions to Zoology 596 [Boury-Esnault N & Ruetzler K. (eds)]: 55 pp., 305 figs.</SOURCE>

83600 <ABSTRACT>This is a vademecum of terms for describing all aspects of sponge morphology, such as habit, surface structure, consistency, and anatomy. Definitions of microscopic features include aquiferous system, cytology, reproductive structures, skeletal architecture, and calcareous and siliceous spicules. Terms were selected and reviewed by an international group of 10 experts in sponge systematics, during several workshops. Each entry is accompanied by a precise diagnosis and an illustration. Terms listed as "rejected" are those judged unsuitable, redundant, or preoccupied. The thesaurus will aid descriptions in future systematic papers, computerized data banks, and identification keys. The literature cited presents a historical perspective on similar attempts to create a precise terminology of sponge morphology and helps to further clarify the selected terms.

83611 <TITLE>Application of fluid transport design theory to sponge functional morphology.</TITLE>
83612 <SOURCE>Indiana University, Bloomington; unpublished M.Sc. thesis; 79 pp.</SOURCE>
83613 <ABSTRACT>Certain extant sponges exhibit canal architecture consistent with engineering fluid transport design theory and this has been used to interpret functional morphology of putative fossil sponges (stromatoporoids). Canal systems of two species of modern sponges were impregnated with colored resins and canal diameters were measured. Three functional models were tested: diffusion-based transport; non-optimal bulk-flow transport; and optimal bulk-flow (Murray's Law) transport. Optimal bulk-flow transport minimizes the metabolic costs of moving fluid through the system and the metabolic costs of maintaining the system. A diffusion-based transport system, regulated by Pick's first law, would exhibit uniform cross-sectional areas within the aquiferous modules. In this type of system the sum of all canal diameters squared should therefore remain constant. In non-optimally designed bulk-flow systems, governed by Poiseuille's Law, flow is proportional to the fourth power of the radius, and the diameters to the fourth power would sum to a constant. Systems obeying Murray's Law would exhibit a cubic relationship and the diameters to the third power would sum to a constant. For the modern sponges statistical tests show that the diffusion-based hypothesis can be rejected while both non-optimal and optimal bulk-flow hypotheses are accepted. Murray's Law assumes an optimal design, and morphology does not have to optimize a function to have adaptive significance. If a putative fossil sponge conforms to Murray's Law, then a sponge affinity is logical. However, if the architecture is inconsistent with Murray's Law, a sponge affinity cannot be rejected. - 83651 <SOURCE>Bulletin de la Societe geologique de France 165, 1: 77-84.</SOURCE>
- 83652 <ABSTRACT>The two common calcium carbonate polymorphs, calcite and aragonite, have been alternatively predominant in both sediments (Sandberg 1983) and in skeletal carbonates (Wilkinson 1979), in particular in those secreted by sponges (Cuif and Gautret 1991a). Changes in water chemistry and variations in temperature are often used to explain these oscillating global trends (Railsback and Anderson 1987). However, these parameters are not adequate to justify why, under the same diagenetic conditions, the skeletons of sponges and corals do not undergo the same mineralogical transformations, especially in Upper Triassic deposits. To interpret this anomaly it is necessary to take into account the peculiar feature of biogenic carbonates produced by the two taxa, the presence of an organic matrix closely linked to the mineral phase. This matrix, secreted during skeletogenesis, has two presumed functions: binding of calcium ions and orientation of crystal growth. Even after death and burial of the organisms, strong molecular interactions between the organic - mainly proteinaceous - and the inorganic phases will be maintained. The divergent diagenetic trends observed in sponge and coral skeletons could be partially induced by the biochemical differences in the organic matrix. [part of extensive summary]</ABSTRACT>

83702 <TITLE>The Sponge Organisms: Discussion and Comments.</TITLE>
83703 <SOURCE>FCnP 13, 2: 29.</SOURCE>
83704 <ABSTRACT>Speculations about the origin of early archaeocyathid sponges and coelenterates have caused many authors to reexamine data of such fossils as the Stromatactis problematica, the stromatoporoid and the lithistid faunas. But the sponges can also be classified as organisms occupying a position in an hierarchic energy-flow between flora and fauna. In terms with the palaeontological taxonomy they should be placed within the Archaeocyatha super-phylum or the sponge organisms. The super-phylum would include the Archaeocyatha phylum (sub-phylum Stromatactis problematica and sub-phylum Archaeocythidae with intermediate class of the petrobionid flora, including the Receptaculites biocoenosis type A) and, of course, the Porifera phylum. * The Porifera phylum includes the Porifera sub-phylum and a newly defined Stromatoporata sub-phylum. The Stromatoporata sub-phylum, showing signs of renaissance, envelopes the classes Stromatoporidae, Chaetetidae (including Tabulaospongiae) and the Sclerospongiae (as described by E.F. Goreau & W.D. Hartman 1969: 8th Meeting, Association Island Marine Laboratories, Jamaica). * The petrobionid floral organisms should also be considered within the sub-phylum to accord with their type and spicules in so far, as regulations of water flow and aquasity are concerned (see G. Termier: FCnP 6, 1:). * Several studies made on sclerosponges and demi-sclerosponges (i.e. Chaetetidae) show wide histological and structural variations (cf. J. Vacelet & C. Levi 1958: C.R. Acad. Sci. Paris 246; C.W. Stearn 1972: Lethaia 5), leading many scientists to consider the Porifera as animals. * Mais, les sponges: d'organisation au d'animaux? Stromatatactis problematica may well claim dinoflagellate symbionts. [full text of a paleontological note]</ABSTRACT>

83728 <TITLE>On the origin of Hexasterophora and Amphidiscophora with a
special remark on Itararella gracilis and Microhemidiscia ortmanni
Kling & Reif (1969); an important but largely disregarded
documentation.</TITLE>
83729 <SOURCE>FC&P 18, 2: 26-28.</SOURCE>
83730 <ABSTRACT>In some hexasterophoran taxa (the dictyonal Hexactinosa and
Lychniscosa, and partly the lyssakine Euplectelliidae) the main
parenchymalian spicules are fused into a siliceous basal skeleton. The
resulting rigid skeletons are likely to be preserved as fossils, and
thus the hexasterophoran hexactinellids are well-documented in the
fossil record (e.g. in the Upper Jurassic of Swabia and in the Upper
Cretaceous of Northern Germany). * In contrast no recent
Amphidiscophora possess fused spicules, and so far we have no evidence
of any fossil amphidiscophoran hexactinellids with rigid skeletons. For
this reason, the fossil record of amphidiscophoran hexactinellids is
extremely poor and mainly consists of isolated amphidiscs. [fragments

83819 <TITLE>On the concept of "reticulate evolution" from a sponge
's viewpoint.</TITLE>
83820 <SOURCE>FC&P 28, 2: 14-16.</SOURCE>
83821 <ABSTRACT>The assertion that "for most taxa, there is no meaningful
interface between molecular systematics and morphological taxonomy"
(Veron 1999: sendai symposium, book of abstracts, p. 9) does not hold
true. For many good reasons, some of which result directly from
molecular biological research, we can safely reject the concept of "
reticulate evolution". [excerpt from a short note]</ABSTRACT>

83884 <TITLE>The genus Batzella: a chemosystematic problem.</TITLE>
83885 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Biologie 66, suppl. 1996 [Willenz P. (ed.): Recent advances in sponge biodiversity inventory and documentation]: 89-101.</SOURCE>
83886 <ABSTRACT>Biogenetically unrelated cyclic guanidine alkaloids and pyrroloquinoline alkaloids have been reported from sponges assigned to the genus Batzella. These sponges have been assigned to this genus because of their possession of a simple complement of thin strongyles in irregular plumoreticulate arrangement. Cyclic guanidine alkaloids were first reported from an alleged axinellid species from the Caribbean, Ptilocaulis aff. P. spiculifer, and subsequently from a second Caribbean specimen identified as Ptilocaulis spiculifer and at the same time from a Red Sea poecilosclerid, Hemimycale sp. Closely related compounds were described from a Caribbean specimen identified as Batzella sp. and also from the poecilosclerids Crambe crambe (Mediterranean) and Monanchora arbuscula (Brazil). Isobatzellins (pyrroloquinoline alkaloids) were reported from a black deep-water species from the Bahamas identified as Batzella sp. [initial part of extensive summary]</ABSTRACT>

83897 <TITLE>Comments on the Caunopora Tubes: stratigraphic distribution and microstructure.</TITLE>
83898 <SOURCE>Palaeontographica Americana 54: 501-508 [Oliver W.A.Jr et al. (eds): Recent advances in the paleobiology and geology of the Cnidaria: Proceedings of the 4th International Symposium on Fossil Cnidaria].</SOURCE>
83899 <ABSTRACT>Caunopores are usually considered tubes of commensal tabulates in stromatoporoids, and have been noted in 27 stromatoporoid genera. The stromatoporoid genera most often allied with caunopores are Stromatopora, Stromatoporella and Clathrodictyon. Caunopores are very frequent in Middle Devonian stromatoporoids, and possibly disappear at the top of the Givetian; indeed, the presence of caunopores in Frasnian stromatoporoids is doubtful. Caunopores are usually referred to Syringopora but the microstructure of the caunopores is very different from the lamellar microstructure of Syringopora. [original summary]</ABSTRACT>

- 83938 <ABSTRACT>Skeletal characters of Spongiomorphids have been established by reference to microstructural features of Spongiomorpha acyclica Frech. Also the other Triassic forms from Fischerwiese (Zlambach beds, South-Austria) initially gathered in Spongiomorphids are reexamined and their microstructures described. The study evidences the homogeneity of microstructures and modalities of growth in 5 among these species, otherwise strictly identical to a Triassic family of scleractinian corals, the Astreaeomorphidae, the diagnosis of which has been recently emended, taking in account microstructural features. It is proposed to integrate Spongiomorphids to this family, except for S. (Heptastylopsis) ramosa differing by its typically trabecular microstructural organization.</ABSTRACT>

- 83977 <ABSTRACT>The work includes 16 articles, devided into 4 sections : I - Ecology and Systematics, II - Synecology, Ecostratigraphy and Paleobiogeography, III - Environment, IV - Organogenous buildups. Various aspects of the connection between the environment and the organism are considered in all the articles. Two first sections unite

- the articles dedicated to the methods of the use of the ecological observations necessary for the Systematics of some groups of biostratigraphical constructions. The articles of section III are dedicated to the characteristic of the environmental conditions of the organism's life, consider the significance of some nonbiotic factors for the development of the life on the Earth and peculiarities of settling of the organisms in the ancient basins as well. The last forth section includes two articles, considered various types of organogenous buildups and issues of the terminology.

84003 <ABSTRACT>Dans le cadre du 3ème cycle en Sciences de la Terre des universités de Suisse romande l'Université de Berne a organisé en mars 1984 un cours sur la géologie et la paléoécologie des récifs. Ce cours est tenu à l'Institut de Géologie de l'Université de Berne et a duré 10 jours. * Le cours adressait aux géologues diplômés de toutes les universités de Suisse romande. Le but du cours était de donner une synthèse d'intérêt général des connaissances actuelles dans le domaine des récifs. Pour cela 22 spécialistes avaient été invités comme enseignants à donner les conférences. * Les contributions des différents conférenciers sont contenues sous forme condensée dans notre volume.</ABSTRACT>

84067 <SOURCE>Journal of sedimentary Petrology 54, 2: 425-431.</SOURCE>
84068 <ABSTRACT>Intragranular, micritic cement has been observed in microborings from deep-sea sedimentary particles (pteropod shells), depths 528 m to 871 m. It is particularly conspicuous in non-depositional environments such as the Blake Plateau. Such cementation may be concurrent and analogous to the formation of intergranular deep-sea cement. It can occur at such energy levels where particle-to-particle contacts do not persist for sufficient time to allow intergranular cementation.</ABSTRACT>

84079 <TITLE>Reefs are not so different - They follow the evolutionary pattern of level-bottom communities.</TITLE>
84080 <SOURCE>Geology 13: 46-49</SOURCE>
84081 <ABSTRACT>There is a pervasive attitude that reefs were isolated from the mainstream of evolution and that their history had quite a different pattern from the level-bottom marine biota. However, three striking similarities exist between the evolution of reefs and other marine communities. (1) Reef composition and ecologic structure were governed by the composition of the three Phanerozoic evolutionary faunas. (2) Reefs were decimated by the major extinction events of the geologic record. (3) Reefs conform to the pattern of level-bottom community evolution. Intervals when reefs were absent were due either to the absence of appropriate frame-building organisms in the biota (for example in the Middle and Late Cambrian) or to the absence of reefs following extinction events before frame-building organisms re-evolved a reef-building mode of life.</ABSTRACT>

84131 <TITLE>PaleoTax - a database program for palaeontological data.</TITLE>
84132 <SOURCE>Computers & Geosciences 30, 5: 513-521.</SOURCE>
84133 <ABSTRACT>PaleoTax is a windows-based relational database program to record, analyse, and output palaeontological data. The program is taxon-based and handles taxonomic, stratigraphic, and geographic data. Its structure is relational and subdivided into literature, stratigraphy, geography, sample material, taxonomy, and literature citations. It encompasses 39 tables and 254 data fields. Additional tables and fields can be added, depending on the user's needs. The edit forms, which can also be modified, are not part of the program. The main purposes of PaleoTax are to record data obtained from the literature and to serve as an information system. Once they have been recorded, data can be sorted and searched for under various aspects. PaleoTax generates reports in ASCII, RTF, and HTML for the most important tables, such as species, genera, and localities, and can export the whole database as a large catalogue in the form of the classic Fossilium Catalogus or as an Internet application. Data analysis is an important part of PaleoTax: a program interpreter provided with PaleoTax makes it easy for the user to analyse the data and to display the results as graphs. The analytical results can also be exported as ASCII files. [original abstract]</ABSTRACT>

84235 <TITLE>Discussion on Definition Method of Microstructural Units of
Invertebrate Skeletons. </TITLE>
84236 <SOURCE>Acta Palaeontologica Sinica 26, 1: 49-54. </SOURCE>
84237 <ABSTRACT>The use of microstructural characteristics of calcareous
skeletons is rapidly growing in invertebrate palaeontology (Chen 1985).
In the 19th century, the method was applied to some zoological groups
(i.e. Madreporaria), but it was only after the great improvements given
by Boggild and others that it has been generally accepted. These works
are founded on the definition of different basic microstructural
components, the arrangement of which provides various kinds of skeletal
tissues. This paper makes an attempt to show that a relevant definition
of these fundamental units requires progress in two directions of
observation. Firstly, it is now obvious that the basic microstructural
components (i.e. prisms, lamellae, etc.) may have greatly different
internal organizations related to the diverse taxa in which they were
observed. For instance, it is shown here that the so called simple
prisms of two lamellibranch genera (Pinna and Trigonina) have very
distinct structural features, which appear only in samples treated with
adequate preparative methods (enzymatic proteolysis, or decalcification
with fixative mixtures). Secondly, it also seems necessary to bear in

mind the general organization of the secretory layer of the pallial edge, and its relations with the orientation of the microstructural components. Some evidences are given in this way by comparing the typical crossed-lamellar tissue of Acrosterigma and Vepricardium, with the external layer of the Dosinia, which has long been considered as some kind of prismatic composite.</ABSTRACT>

84248 <TITLE>Spatial variations in the porosity development of carbonate sediments and rocks.</TITLE>

84249 <SOURCE>Facies 18: 181-204.</SOURCE>

84250 <ABSTRACT>Diagenetic sequences of many stages are known from various carbonate rocks but the diagenetic spatial variations within a given facies, outcrop, hand specimen or thin section are only gradually rediscovered and taken into account in porosity studies. The variations occur in various carbonate facies such as reefs, beachrocks, shallow-water deposits, hardgrounds and concretions. Multiple parallel diagenetic pathways branching in time are recognized in such cases. […] Realization of spatial variations in porosity development spoils fast and simple correlations, assessments, or predictions. The synthesis of the detailed analytical information, however, provides a route toward application of diagenetic complexities. [abridged extensive summary]</ABSTRACT>

84275 <SOURCE>Acta Palaeontologica Sinica 27, 4: 521-524.</SOURCE>

84276 <ABSTRACT>This paper discusses the automatic classification of paleontologic fossils by micro-computer. It is pointed out that the system of paleontologic taxonomy can be represented by predicate formulas and the fossils can be automatically classified by means of predicate calculus. Taking into consideration the features of paleontologic taxonomy, the authors have put forward a control strategy

for the rule selection, which greatly raises the operating efficiency. The paper also discusses the computer program for paleontologic taxonomy. Through practice it has been proved that the approach given here is very effective.</ABSTRACT>

84288 <SOURCE>Senckenbergiana lethaea 69, 3/4: 315-368.</SOURCE>

84289 <ABSTRACT>A review of the geological record of reef-building activity shows it to have been episodic, the associations of the principal frame-builders tending to change from episode to episode. It is argued that this episodicity may have been, in part, a reflection of the changing pattern of symbiosis and extinctions through time, new groups of organisms, becoming associated with photosynthesizing algae and thus developing the capacity for extravagant, skeletal growth.</ABSTRACT>

84313 <TITLE>Syn-depositional alteration of coral reef framework through bioerosion, encrustation and cementation: Taphonomic signatures of reef accretion and reef depositional events.</TITLE>

84314 <SOURCE>Earth-Science Reviews 86, 1-4: 106-144.</SOURCE>

84315 <ABSTRACT>The development of coral reef framework and the preservational character of both in-situ and rubble coral is strongly influenced by a range of physical, chemical and biologically-mediated taphonomic processes. These operate at, or just below, the reef framework-water interface and can be defined as having either a constructive or destructive effect upon primary reef framework (i.e., coral) constituents. Constructional activities add additional calcium carbonate to the primary framework structure via secondary framework growth and early cementation. Destructive processes, which remove or degrade primary (and secondary) framework carbonate, are associated

with the effects of either physical (mainly storm) disturbance or biological erosion (termed bioerosion). Key bioeroding groups include the grazing fish and echinoid groups, as well as the activities of an array of infaunal borers. These include specific groups of sponges, bivalves and worms (termed macroborers), as well as cyanobacteria, chlorophytes, rhodophytes and fungi (termed microborers). The relative importance of each process and the rates at which they operate vary spatially across individual reef systems. In addition, many of these processes leave distinctive signatures on, or in, the coral framework. In some cases (e.g., calcareous encrusters) these are the skeletons of the organisms themselves, whilst in other cases the organism may leave behind a trace of their activity (e.g., macro- and microborers). These represent useful palaeoenvironmental tools, firstly because they often have good preservation potential and, secondly because the range and extent of many of the individual species, groups and processes involved exhibit reasonably well-constrained environment and/or depth-related distributions. As a result these taphonomically important organisms or processes can be used to delineate between reef environments in core or outcrop, and to aid the interpretation of reef depositional processes and events. This review summarises current understanding regarding the distribution of these species/processes within contemporary reef settings and considers the suites of taphonomic signatures that may aid in the recognition and interpretation of depositional environments and events.

84430 <TITLE>Computer modeling the internal architecture of carbonate platforms.</TITLE>
84431 <SOURCE>Geology 18: 26-30.</SOURCE>
84432 <ABSTRACT>A numerical computer model is described that calculates the internal architecture of carbonate platforms in response to varying values of carbonate production, subaerial and submarine erosion, sediment redeposition, and sea-level changes. The computer-generated sections closely resemble large-scale outcrops and interpreted seismic profiles through carbonate platform. Stillstand and transgressive sequences have prograding and downlapping platform geometries with lagoons developing in transgressive systems. Regressive sequences have downlapping clinoforms and erosional upper surfaces. Glacioeustatic scale cycles have a major control on platform geometry with erosional sequence boundaries developing during low stands and platform drowning occurring during transgressive periods. Lowstand downlapping wedges are minor features when compared with clastic systems, and major progradation and downlap of slope deposits develop with transgressions and flooding of platform tops. Carbonate erosion rates are varied and have an important effect on the morphology of floodback surfaces, which have a major control on platform top production. The computer program contributes to the analysis of carbonate systems in two ways: it gives a visual picture of the quantitative effects of the many parameters controlling carbonate geometries, and it aids quantitative analysis of the architectures and time scales of ancient outcrop or seismic sequences.</ABSTRACT>

84469 <TITLE>The Evolution of Reef Structures through Time: Importance of Tectonic and Biological Controls.</TITLE>
84470 <SOURCE>Facies 22: 159-168.</SOURCE>
84471 <ABSTRACT>The evolution of reefs is controlled by biological and global factors. The paper stresses the importance of the tectonic and paleogeographical control. The evolution of reefs is reflected by the changes in the composition of reef-building communities during geological time, by changes in the mineralogical composition of reef carbonates, and by changes in types, sizes and tectonic settings of reefs. The composition of reef-building communities is characterized by the development of new adaptive patterns with decreasing diversity, by migration of reef-building organisms to low-level communities, and by total or partial extinction of reef organisms. Several changes in the composition of reef carbonates (calcite, Mg-calcite, aragonite), strongly dependent on the skeletal mineralogy of the reef organisms, are evident during Riphean and Phanerozoic times. These changes coincide only roughly with the long-time intervals recognized for the mineralogical composition of non-reefal carbonates. Reef types started with the small organic buildups of the Proterozoic and the Early Cambrian followed by the differentiated reefs of the late Cambrian, the dome-shaped pinnacle reefs and atolls of the Ordovician, and the strongly differentiated reef-complexes of the Silurian and Devonian. The importance of bioherms decreased during the Mesozoic and Caenozoic. Reef structures increased in size during geological time from Precambrian and Cambrian (height - elevation above off-reef basinal bottom: several meters) to Ordovician (height several hundreds of meters), Devonian (more than 1000 meters) to Caenozoic reefs (up to 2000 meters). Increase in thickness (of the total reef structure) and elevation above sea bottom was connected with an increase in the number of facies types. [abbreviated summary]</ABSTRACT>

84509 <SOURCE>P.S.Z.N. I: Marine Ecology, 3, 3: 193-212.</SOURCE>
84510 <ABSTRACT>In remembrance of the death of Charles Darwin 100 years ago, a review is given on his coral reef research from the point of view of present knowledge. Although during Darwin's time no one was aware of the changing level of the glacial sea or of the important function of the symbiotic zooxanthellae in the life of hermatypic corals, his observations and considerations on the ecology of corals and on the formation of coral reefs are relevant to this day. But of course his ideas need new causal interpretations. The origin of the different reef types can no longer be explained by subsidence only, but by different modes biologists and geologists described during the following century. To summarize all the many existing theories, the all enclosing theory of compensation is put forward here in honor of this great man.</ABSTRACT>

84601 <ABSTRACT>The data occurring in palaeontology are analyzed. The characteristics of the extant and fossil organisms are divided into five basic units of data: - morphology, - ecology, - taxonomical relations, - stratigraphical and - (palaeo-) geographical occurrence. Six data complexes are divided from these units. Their relationships are defined and the database structures designed on the basis of the Entity-Relationship-Model. The data structures are described in detail and advice is given for building up databases. The various opportunities of querying the database and particularly of assessing the data are thoroughly discussed. Data obtainable by transactions on the stratigraphical and (palaeo-)geographical distribution of the organisms are considered. Finally, the database on post-Palaeozoic corals compiled by the author is introduced and some first results as well as future projects are represented.</ABSTRACT>

84666 <ABSTRACT>Reef development is usually described either in terms of long-term ecologic succession or merely as the result of facies migrations. In fact, many spatio-temporal levels of development could be represented by patterns preserved in reef sequences, including (in ascending scale): processes involving growth of individual organisms, colonization and ecologic interactions; ecologic succession and environmentally-driven succession-like processes; community replacement

owing to habitat changes; large-scale regional processes of reef growth; and, at the most inclusive level, community evolution. Because of abundance of durable frame-building and binding organisms, and potential for rapid envelopment and early lithification, reefs and other bioconstructions may contain evidence of all these levels of biotic change through time.

84692 <ABSTRACT>Three sections have been studied in the area between Couvin and Villers-la-Tour, at the southern margin of the Dinant Synclinorium. They expose Upper Emsian and Lower Eifelian strata (Eau Noire and Couvin Formations). The coral fauna (Rugosa, Tabulata and Chaetetida) has been examined in detail and a new species of the rugose coral genus *Thamnophyllus*, *T. turritum*, is described. Parasites and commensals of corals and Chaetetids are also recorded. Six microfacies families are described and interpreted in terms of sequential analysis. This analysis shows a regressive progradational megasequence on a ramp lacking a continuous rim and typical lagoonal facies.</ABSTRACT>

84730 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunkel F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
84731 <ABSTRACT>Data obtained from Lower Cretaceous mud mounds provide evidence for organic matrix mediated micrite production in place. Intracrystalline organic macromolecules are typically enriched in Asp and Glu. Mineralization is confined to non-living organic substrates (organomineralization of Trichet & Defarge 1995) originally derived from microbes, biofilms and / or metazoans. For seeding and epitaxial overgrowth organic substrates and seed crystals need a persistent interaction with the surrounding medium. Therefore, sedimentary starvation is required. Sedimentary starvation is realized via protected space (semi-closed cavities, interstitial pore space, sponge body container), via rapid sealevel rise (TST-confined mud mounds), via rapid drop of sealevel (emersion), and analogue episodes of low carbonate production presumably controlled by eutrophism. Crystal growth also requires an increased carbonate alkalinity. This is provided via sulfate reduction on local scale and / or via continental weathering in the surrounding Paleozoic massifs. Genetically, mud mounds of the Soba Reef Area correspond to organomicrite reefs. These reefs are opportunistic, i.e. their occurrence within the photic zone indicates major crisis of the stenotopic scleractinian coral / calcareous algae community. Mud mounds of the Soba Reef Area share some important features with Albian / Cenomanian hardgrounds (organomicrite related lithification, dominance of active filter feeding organisms, restriction of sediment supply) but hardgrounds were influenced by stronger submarine dissolution and were exposed to relatively strong current systems.</ABSTRACT>

84744 <ABSTRACT>In the area of the western Swabian Alb more than 1,000 samples of well bedded Upper Jurassic limestones, marls and of spongiolithic buildups were analyzed with regard to their insoluble residues. The silt-sized residues consist of quartz, feldspar, pyrite and rare apatite. The clay-sized residues consist of illite respectively illite / smectite mixed layer, chlorite and kaolinite. The distribution of both the clay mineral association and the geometry of the illite / smectite mixed layer X-ray pattern show distinctive differences within the sequence which can be used for a stratigraphic subdivision of the Upper Jurassic series.</ABSTRACT>

84756 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
84757 <ABSTRACT>Reef geometry is controlled by internal and external factors. Biological and paleoecological changes represent the most important internal factors. Changes in accommodation space due to (eustatic?) sealevel fluctuations and/or changes in total subsidence as well as variable sediment production and input constitute important external factors for reef development. Variations of any factor result in e.g. aggradational, progradational or retrogradational stratal patterns of reefs or in "drowning". On a broader scale, these internal and external factors influencing reef geometries also control the development and the different types of carbonate platforms (ramps, shelves, etc.). The resulting geometries can be modeled by stratigraphic simulation programs, e.g. PHIL 5.1, which are able to vary the important internal and external factors controlling sedimentation.</ABSTRACT>

<ABSTRACT>A comprehensive computer database of ancient reefs provides new insights in global and regional changes of positions of reefs (shown in updated paleogeographical maps), biotic composition and diversity as well as constructive and destructive processes. The investigation was focused on Pangean reefs (Carboniferous to Jurassic). Current studies enlarge the database and contrast reef distribution and composition data against secular Phanerozoic trends.

- 84783 <ABSTRACT>Reef growth is the outcome of a positive feedback between carbonate production and carbonate stabilization. This basic game has been played by a variety of organisms of many different taxa through the Phanerozoic. This self-enhancing growth potential is cut back by a number of environmental factors such as depth dependent growth potential, erosion and sealevel changes. This basic concept is the backbone of our computer-based reef model. It is cast into a mathematical form by a Fisher equation adapted to the specifics of reef growth, such as dependence of production rate on light and water depth, erosion and redeposition. The solution of this equation is the reef topography represented by reef height as a function of region and time. The solutions can be represented as 3-d topography or vertical sections thereof. The latter allow for sequence stratigraphic analysis.</ABSTRACT>

84794 <TITLE>The role of magnesium in the crystallization of calcite and aragonite in a porous medium.</TITLE>
84795 <SOURCE>Journal of Sedimentary Research 66, 3: 482-491.</SOURCE>
84796 <ABSTRACT>Morphological development of calcite crystals is related to supersaturation conditions during growth. Crystallization of calcium carbonate (calcite and aragonite) as well as Mg-calcite was studied under controlled supersaturation conditions by the counter diffusion of Ca²⁺ and CO₃²⁻ ions through a porous transport medium (a column of silica gel). Under our experimental conditions, where ion transport is constrained to be diffusion controlled, nucleation and growth take place under conditions of high supersaturation, the actual threshold value of the supersaturation depending on the supersaturation gradient. In the pure CaCO₃ system, calcite grows at lower supersaturation than aragonite. The calcite develops relatively simple rhombohedra while the aragonite grows as spherulites. Presence of Mg²⁺ in the interstitial fluid inhibits nucleation, increasing the threshold supersaturation at

which crystallization begins. The resulting Mg-calcite crystals show a range of morphologies depending on the Mg content and the supersaturation at the point of crystallization. At high values of supersaturation, up to 15 mol% MgCO₃ is incorporated into the calcite and the crystals form spheres. At lower supersaturations, Mg content decreases and morphologies change progressively through a well-defined and reproducible sequence from spheres to dumbbell-like forms to wheat-sheaf-like bundles and eventually single crystals with steep rhombohedral faces. The crystals are compositionally zoned, showing both sector and oscillatory zoning. The compositional evolution is related to the supersaturation and interface roughness during crystal growth.

84821 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 007-013.</SOURCE>
84822 <ABSTRACT>Marine organic reefs are biological-paleobiological features; they are not sedimentologic-stratigraphic features resulting from locally over-thickened accumulations of sediment. The positive topographic relief of reefs is due to the relatively rapid upward growth, skeletal strength / rigidity and high packing density of the clonal (or gregarious) organisms comprising the reef framework. In modern, tropical reefs, these features reach their acme at the relatively narrow, shallow water crest marking the interface between the backreef lagoon or reef flat and the forereef or seaward slope. In ancient reefs, sediment commonly comprises a much greater volume of the reef than the framework. However, it is the organisms, preserved either in their original growth positions or in situ, that distinguish reefs from accumulations of transported skeletal debris on level-bottom substrates. Both modern and ancient reef communities have characteristic taxonomic compositions, diversities and guild structures. It is the relative skeletal volume (or areal coverage) of members of the constructor, baffler and binder guilds that controls the reef-building prowess and in ancient reefs becomes the basis for their classification as framestones, bafflestones and boundstones, respectively.</ABSTRACT>

84833 <TITLE>Ist Konstruktionsmorphologie ein Aktualistisches Prinzip der Palaeontologie? </TITLE>
84834 <SOURCE>Courier Forschungsinstitut Senckenberg 201: 145-160.</SOURCE>
84835 <ABSTRACT>Constructional Morphology was developed as a continuation of questions and methods introduced in the concept of aktuopaleontology. The foundation of the principle of "Aktualismus" or Uniformitarism is attributed to Lyell (1830-1833), Gressly (1838) and Walther (1893). Using the present conditions as a key to the past, Schaeffer (1962) developed the principle of uniformitarism into the concept of aktuopaleontology by drawing on several research methods such as ichnology, taphonomy, functional morphology and facies reconstructions. Presupposing that there is a difference in understanding functions in the environment and the working of the whole organism, the group "Kritische Evolutionstheorie" developed a new concept of organisms as hydraulic energy conducting entities. Reconstructions can be performed for recent as well as for fossil organisms; the analysis of fossil organisms makes reference to constructional models developed for recent organism. Many of the terms and concepts of the constructional theory of organisms are based on ideas of Schaeffer. In this text it is demonstrated that constructional morphology can be seen as a continuous development with aktuopaleontology as its starting point. It is shown to be a principle of uniformitarism. The soft body reconstruction of rugose corals is given as an example, based on the generalized representation of rugose skeleton ontogeny from Schindewolf (1950) and the constructional model for recent anthozoans.</ABSTRACT>

84846 <TITLE>Nature and origin of organic matter in carbonates from speleothems, marine cements and coral skeletons.</TITLE>
84847 <SOURCE>Org. Geochem. 26: 361-378.</SOURCE>
84848 <ABSTRACT>Organic matter in speleothem calcite, marine carbonate cements and aragonitic coral skeletons was studied to determine its location, molecular structure, functionality and effect on mineral growth. SEM analyses showed that inorganically precipitated carbonates incorporate, during growth, adsorbed organic matter between submicroscopic subunits of the crystals whereas biologically secreted carbonates incorporate biogenic tissue between the crystals. Molecular fluorescence spectroscopy indicated that low molecular weight fulvic acids are the most important constituents of the organic matter. The fulvic acids are probably derived from soils (speleothem calcite), dissolved organic matter (marine carbonates) and biological decay products (aragonitic coral skeleton).</ABSTRACT>

84860 <SOURCE>Coral Research Bulletin 05: 239-246.</SOURCE>
84861 <ABSTRACT>In this study the stratigraphic range and geographic distribution of Famennian solitary rugose corals, not or poorly disseminated, corresponding to the Cyathaxonia-fauna and belonging to the Dzungar-Hinggan Basin (N China), were analysed in detail. Coral fauna is well preserved in the Hongguleleng (Hongguleleng area, North Xinjiang, NW China) Hongermiao (Xuguit Qi area, Inner Mongolia, NE China) and Upper Daminshan (Sonid Zuoqi-Abag Qi areas, Inner Mongolia, NE China) Formations. The studies of the distributions of sixteen generic taxa known up to now in this basin allows us to confirm the existence of endemic taxa (Honggulasma and Hebukophyllum), significantly amplify the stratigraphic distribution of Nicholsoniella and Caninia and to ratify for the rest of the genera (Petraiaella, Guerichiphyllum, Friedbergia, Gorizdronia, Kozłowskinia, Nalivkinella, Ufimia, Cyathaxonia, Catactotoechus, Metriophyllum, Syringaxon and Amplexus) a similar distribution to what other Famennian basins in the rest of the world have. Besides, the geographic distributions of these same taxa imply fairly strict relations of the Dzungar-Hinggan Basin with the North East of Siberia (Omolon Region), Urals and Eastern Europe (especially Poland), along the North and west edges of the Proto-Thetys Ocean.</ABSTRACT>

84872 <TITLE>Image analysis of thin sections: Implication for calcite fabric of diagenetically changed coral skeletons.</TITLE>
84873 <SOURCE>Coral Research Bulletin 05: 171-179.</SOURCE>
84874 <ABSTRACT>Image analysis enables the detection, separation and series-ordering of diagenetical stages. Early diagenetical growth of fibral tufts was largely confirmed including the specific reactions with ambit of the sclerenchyme. The regularly dominant "tablet" [= short c-axis] crystal population are utterly assigned to late diagenetical stages. Eventual early populations of "tablet" calcite crystals are not satisfactory detected during our studies. Nevertheless, the crystallization of the early tablets is theoretically possible. The microenvironment of these domains has to be separated by membranes and the survived tablet generation has to be marked by solution-sutures on crystal margins. In previous studies on coral microstructures, the late origin of tablet crystals has been either supported (J. Sorauf) or refused (J. Lafuste). We can suggest a future test of the potentially conflicting results: a comparison of ultra-thin sections and image-analytic series based on thin sections (i.e. from approximately the same place of the skeleton).</ABSTRACT>

84886 <SOURCE>Kleine Senckenberg-Reihe 24; 186 pp; 160 figs.</SOURCE>
84887 <ABSTRACT>Exhibition catalogue of the Senckenberg-Museum (Frankfurt am Main) incorporating 25 contributions of German reef-scientists compiled within the scope of the International Year of the Reef 1997. This booklet is meant as a catalogue to the special exhibition of the same name that can be visited until November 16, 1997 in the Senckenberg-Museum (Frankfurt am Main). It is about reefs, those spectacular settlements below the sea-level, which were built for example by corals, sponges and bivalves. It gives details on reefs and their constructors during the "Erdgeschichte". The first reefs developed at least two billion years ago, so called stromatolite-reefs, which are the most important reefal structures at that time. Other types of fossil reefs and their constructors, for example coral reefs of the Devonian Era or the fascinating rudist-reefs of the Cretaceous, are described. Information about excursions to several localities of fossil reefs in Germany is given. Not only fossil reefs are considered, living coral reefs and the role they play for mankind (fishery, biological resources for pharmaceutical products, a.s.o.) are also taken into account. Several contributions cover the endangerment of recent reefs, caused by pollution of the oceans, the cut down of tropical rain forests or excessive tourism and give advice for travellers, visiting those areas, to save the "marine rainforests ". The booklet presents the results of research-projects within the scope of the development of reefs, promoted by the Deutsche Forschungsgemeinschaft (DFG). Articles are written in colloquial German and give an extensive information on the grand constructors below the sea not only for Paleontologists or Geologists but especially for the interested laymen. 84899 <SOURCE>N. Jb. Geol. Palaont. Abb. 208: 663-683.</SOURCE>
84900 <ABSTRACT>Fossils have already made their entry into the visual arts. Their usage in ecclesiastical art is doubtlessly novel. The new church windows in the choir of St. Paul's cathedral in Munster may even be unique. Designed by George Meistermann, perhaps the most important German glass painter of this century, the windows illustrate X-ray-photographs of fossils from the Hunsruck-shales of Bundenbach. This peculiarity within ecclesiastical art deserves treatment for its paleontological value. Meistermann surely was aware of the nature of fossils and knew of the importance of fossils in understanding the history of life and its evolution. Thus, the fossils illustrated in the St. Paul's cathedral windows reflect a further meaning: the representation of the perception of natural sciences within the arena

- of ecclesiastical thought.</ABSTRACT>

84937 <TITLE>Secular oscillations in the carbonate mineralogy of
reef-building and sediment-producing organisms driven by tectonically
forced shifts in seawater chemistry.</TITLE>
84938 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 144: 3-19.
[see also GSA today 9, 2: 1-7]</SOURCE>
84939 <ABSTRACT>The primary mineralogy of oolites and early marine carbonate
cements led Sanberg (Nature 305: 19-22) to divide the Phanerozoic Eon
into three intervals of 'aragonite seas'; and two intervals of
'calcite seas'. Hardie (Geology 24: 279-283) has shown that
these oscillations, together with synchronous oscillations in the
mineralogy of marine potash evaporites, can be explained by secular
shifts in the Mg/Ca ratio of sea water driven by changes in the
spreading rates along mid-ocean ridges. The Hardie model also predicts
that high Mg-calcite should precipitate along with aragonite as it does
in today's aragonite sea. We have encountered oscillations in the
carbonate mineralogy of hypercalcifying organisms (ones that have
produced mass skeletons, large reefs, or voluminous bodies of sediment)
that correspond to Sanberg's aragonite seas and that are
predicted by the Hardie model. Particular groups of corals, sponges,
and algae appear to have been dominant reef builders only when favored
by an appropriate Mg/Ca ratio in sea water. [part of extensive summary]

84951 <SOURCE>Palaeontologia Electronica 02, 1: 4p.</SOURCE>
84952 <ABSTRACT>The answers to specific questions addressed to paleontological databases will depend on the taxonomic biases of those entering the data. Recent revision of stromatoporoid genera has reduced generic diversity of Paleozoic stromatoporoids by one-third and affected both temporal diversity trends and paleogeographic diversity distribution. Revision of the genus Amphipora is used to illustrate the consequences of adopting a taxonomic philosophy of "lumping" for studies in generic and specific diversity. The regulation of free access to databases on the internet has been studied by committees of the U. S. Congress and the U. N. World Intellectual Property Organization.</ABSTRACT>

84965 <ABSTRACT>The structure of a data base for handling taxonomic data of paleontology is built up on the basis of the Rules of Zoological Nomenclature. The authors show that the successful use of data banks depends on their structure and that it is necessary to observe certain rules and principles of design. Numerous practical tips are given for readers who wish to build up their own data banks. The system was first used to store the data of the scleractinian corals from the Cretaceous. Several paleontologists prepare or consider to use the system for other fossil animal groups (foraminiferes, paleozoic corals), too.</ABSTRACT>

84989 <TITLE>Contribution of reef building organisms in reef carbonate construction.</TITLE>
84990 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 95-102.</SOURCE>
84991 <ABSTRACT>The reef phenomenon is essentially a biological phenomenon; therefore, it is important to emphasize its biological and ecological aspects in terms of reef construction. However, the role of organisms in the construction of a reef is manifold. Many organisms play more than one role in the production of reef carbonate. They may produce reef carbonates, either independently or by cooperation with other groups of organisms. The ways in which organisms contribute to reef construction can be classified as follows: 1. Framework construction: Production of solid reef bodies with heavily calcified colonies. 2. Consolidation: Cryptic reef organisms occur in cavities and interstices. They encrust and bind reef colonies to consolidate the reef framework. 3. Binding: Encrusting organisms overgrow and bind blocks and debris together to form rigid reef carbonates. 4. Baffling: Branching colonies can slow down water movement and allow sediments to settle. 5. Stabilizing: Lamellar organisms may cover the debris or loose sediments and would protect them, thus enabling their rapid cementation to form rigid reef carbonate. 6. Biocementing: In a protected environment, the colonization of microorganisms can produce large quantities of micrite cement as metabolic byproducts, which would fill the interstices and cement the debris and blocks into a solid reef carbonate. 7. Forming reef carbonate contributors: In clear water environment, microorganisms can immediately form important quantities of self-supporting rigid micritic reef carbonates. 8. Contribution to sedimentation: Their debris may become sediment. The vast quantities of blocks and debris produced by organisms that fill interstices of the frameworks of reef bodies help to increase the reef volume. 9. Co-building: Forming of reef carbonate by cooperation of several different organisms.</ABSTRACT>

85002 <TITLE>Data banks in palaeontology and the need for standardization.</TITLE>
85003 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 419-427.</SOURCE>
85004 <ABSTRACT>Personal computers are increasingly used for scientific work. In palaeontology they are employed mainly for building up data banks on literature and localities, as well as on taxa with their morphological characteristics. Compared with card files and lists, data banks offer the following advantages: - They are not sorted according to a single criterion but allow universal searching according to all criteria.- They permit rapid access to information.- Several data banks can be interlinked. The acquisition of data is mostly a time-consuming process. In order to enable data banks to be exchanged without

difficulty and thus to obviate the need for other institutions having to collect the same data all over again, colleagues are requested to consider the problem of compatibility in their choice of computers and data bank systems. Different computer systems and data formats have so far hampered exchanges. We therefore suggest introducing a data structure standard (especially for IBM compatible personal computers under the operating system MS-DOS). </ABSTRACT>

85015 <TITLE>Nutrients, predation, and the history of reef-building.</TITLE>

85016 <SOURCE>Palaios 8: 526-543.</SOURCE>

85017 <ABSTRACT>The trophic structure of modern tropical benthic communities, especially reefs, is profoundly influenced by ambient nutrient levels and resultant predator characteristics. In oligotrophic regimes the presence of abundant specialist grazers promotes succession and yields climax-stage communities. Such communities produce the classic " framework" reef dominated by large, heavily calcified phototrophs and multiserial mixotrophs. These primary producers bear many antipredator adaptations and have a marked preference for hard-substrates. Increasing nutrient levels favor a transition in the benthos from photo- and mixotrophs via benthic algae to soft-substrate communities of solitary or uniserial heterotrophs feeding on planktonic primary producers. Under such high nutrient conditions, small heterotrophs are perpetually superior competitors, thus maintaining assemblages which resemble pioneer stages. Here, the history of Phanerozoic reef-building is reassessed according to an analysis of trophic structure. Broad global patterns may be largely explained by changes in nutrient availability. Differing rates of oceanic circulation linked to climatic fluctuations and sea-level changes determined the range of trophic regimes available in shallow marine tropical habitats. Most Phanerozoic reefal buildups are revealed as soft-substrate dwelling heterotrophic communities and as such were not well-adapted to oligotrophic conditions: they were trophically quite unlike modern coral reefs and had markedly different environmental requirements. Prolonged phases when heavily calcified multiserial metazoans, although available, did not form framework reefs are postulated as times when few oligotrophic regimes were present in tropical shallow seas, i.e., most of the early Carboniferous, Permian and mid-late Cretaceous. Acquisition of mixotrophic nutrition allowed invasion of previously inaccessible oligotrophic environments, but current evidence suggests that photosymbiosis was not acquired by reef-building organisms until the early to mid-Mesozoic onwards, with the possible exception of the mid-Palaeozoic. This may have been in response to increasing predation pressure and appears to have been facilitated by the creation of extensive oligotrophic regimes. The resilience of Tertiary scleractinian coral reefs to climatic vicissitudes might be largely explained by the rise of anti-fouling grazers, especially fish, during this time.</ABSTRACT>

85028 <TITLE>Microbial Carbonate crusts - a Key to the Enviromental Analysis
of Fossil Spongiolites? </TITLE>
85029 <SOURCE>Facies 29: 41-54.</SOURCE>
85030 <ABSTRACT>Morphological and geochemical comparisons between modern
cryptic microbialites from Lizard Island / Great Barrier Reef and
fossil counterparts in the Upper Jurassic (Southern Germany, Dobrogea /
Romania) and late Lower Cretaceous (Aptian / Albian from Cantabria /
Spain) spongiolitic environments show that there are common factors
controlling the crust formations mostly independent of light despite of
diverging (paleo) oceanographic positions as well as relationships of
competitors. Factors such as increased alkalinity, oligotrophy, and
reduced allochthonous deposition are of major importance. Thrombolitic
microbiolites are interpreted as biologically induced and therefore
calcified in isotopic equilibrium with the surrounding sea water.
Corresponding with shallowing upward cycles, microbial mats which
produce stromatolitic peloidal crusts become more important. Different
bio-markers are introduced for the first time extracted and analyzed
from spongiolitic limestones of lower Kimmeridgian age from Southern
Germany.</ABSTRACT>

85054 <TITLE>Classification and geological significance of biostromes.</TITLE>
85055 <SOURCE>Facies 31: 81-92.</SOURCE>
85056 <ABSTRACT>Biostrome and bioherm were described as terms by Cumings
(1932), and bioherm has become synonymous with reef because of the
discrete mound or lens shape in vertical section. The phrase "reefs
and biostromes" is common in the literature and emphasises that
biostromes are normally regarded explicitly as not reefal structures,
because of the lack of topographic relief and common absence of a
framework. However, the posifion adopted here is that bioherm and
biostrome are most usefully applied to simply describe the outline
shape of an organic accumulation, and not to denote any particular
inherent internal structural organisation. Furthermore, the view here
is that biostromes are most usefully considered as single organic
layers (i.e. beds). Observations of biostromes of numerous ages and
settings indicate that a considerable variety of internal structure

exists within the outline which defines biostrome. Often, the structure comprises frameworks and dense clusters of in-place organisms and is just as much reefal as similar constructions with a biohermal shape. In other cases biostromes consist of beds of skeletal debris consistent with the concept of biostrome used by many workers. These differences demonstrate that classification of biostromes is needed in order to allow comprehensive palaeoenvironmental analysis, and highlight the long-standing problem of using reef to describe organic buildups. For biostromes, autobiostrume, autoparabiostrume, and parabiostrume are introduced to describe a continuum from structures where the constructing organisms are mostly in place (autobiostromes), to mostly debris of the structure (parabiostromes), with autoparabiostrume as intermediate. Allobiostrume, describes biostromes formed of material derived from allochthonous sources, for example skeletal plankton sedimented onto the sea bed. Most biostromes are of calcareous construction and their composition is most adequately described by existing limestone classification terminology. [part of extensive summary] </ABSTRACT>

85080 <TITLE>Bio-ore formation and biomineralization.</TITLE>
85081 <SOURCE>Acta Palaeontologica Sinica 33, 5: 575-592.</SOURCE>
85082 <ABSTRACT>About fifty-five kinds of biominerals are listed and divided into four stages of amorphous, intermediate, matured and fossilized facies. The biominerals are mainly characterized by weak alkali and weak acid salts, calcareous compounds (25 kinds) oxides (12) and oxysalts (32), hydrated (25) or hydroxylated (6) minerals and uniaxial negative crystals or approximately the like. Based on comparison of the element abundance sequence with that in Lithosphere (Ls) and Biosphere (Bs) the biomineral elements can be divided into six groups: (1) Bs Ls Bm-Zn, Cu; (2) Bs Bm Ls - O, C, H, N, S, Cl, As, Se; (3) Bm Bs Ls - P, Br, I, B; (4) Bm Ls Bs - Ca, Sr; (5) Ls Bm Bs - Si, Al, Mg, Ba, F, Pb, Sn, Fe, Ti, Mn, V, Cr, Ni, Co; and (6) Ls Bs Bm - Na, K. Calcium is the most important metallic element in biomineral body because it has a greater cationic radius than Mg, Fe and Na that is demanded by large complex anions, weaker alkalinity than K and Na, and a larger abundance than Sr and Ba. 85094 <SOURCE>Archives of Natural History 19, 1: 39-54.</SOURCE>
85095 <ABSTRACT>South Carolina naturalist John McCrady (1831-1881), a protege of Louis Agassiz, was a pioneer in the study of Hydrozoa in North America. McCrady undertook investigations on hydrozoan life cycles, and provided thorough descriptions of most taxa. At least 20 of the families, genera, and species that he described and named are still recognised as valid. His ideas concerning classification and nomenclature within the Hydrozoa were remarkable for their time. As a result of the American Civil War, personal problems, cultural predilections, and preoccupation with other scientific interests, McCrady discontinued his hydrozoan research after 1860. Thereafter, his efforts in science were devoted to formulating a "Law of Development ", and to criticism of Darwinian theory.</ABSTRACT>

85106 <TITLE>Stable isotope evidence for the origin of diagenetic carbonate minerals from the Lower Jurassic Inmar Formation, southern Israel.</TITLE>
85107 <SOURCE>Sedimentology 42, 1: 147-160.</SOURCE>
85108 <ABSTRACT>The oxygen isotope compositions of diagenetic carbonate minerals from the Lower Jurassic Inmar Formation, southern Israel, have been used to identify porewater types during diagenesis. Changes in porewater composition can be related to major geological events within southern Israel. In particular, saline brines played an important role in late (Pliocene-Pleistocene) dolomitization of these rocks. Diagenetic carbonates included early siderite (d18OSMOW = +24.4 to +26.5‰; d13CPDB = -1.1 to +0.8‰), late dolomite, ferroan dolomite and ankerite (d18OSMOW = +18.4 to +25.8‰; d13CPDB = -2.1 to +0.2‰), and calcite (d18OSMOW = +21.3 to +32.6‰; d13CPDB = -4.2 to +3.2‰). The petrographic and isotopic results suggest that siderite formed early in the diagenetic history at shallow depths. The dolomitic phases formed at greater depths late in diagenesis. Crystallization of secondary calcite spans early to late diagenesis, consistent with its large range in isotopic values. A strong negative correlation exists between burial depth (temperature) and the oxygen isotopic compositions of the dolomitic cements. In addition, the d18O values of the dolomitic phases in the northern Negev and Judea Mountains are in isotopic equilibrium with present formation waters. This behaviour suggests that formation of secondary dolomite post-dates the tectonic activity responsible for the present relief of southern Israel (Upper Miocene to Pliocene) and that the dolomite crystallized from present formation waters. Such is not the case in the Central Negev. In that locality, present formation waters have much lower salinities and d18O values, indicating invasion of freshwater, and are out of isotopic equilibrium with secondary dolomite. Recharge of the Inmar Formation by meteoric water in the Central Negev occurred in the Pleistocene, and halted formation of

dolomite.</ABSTRACT>

85119 <TITLE>Reefs, an elementary principle with many complex realizations.
</TITLE>
85120 <SOURCE>Beringeria 11: 1-99.</SOURCE>
85121 <ABSTRACT>In this work reefs are viewed as the result of self enhancing
feedback circuits. Reef growth comprises enhanced production of
carbonate compared to the surroundings and a better fixation of this
carbonate as compared to the surroundings. Moreover both of these
elementary principles of reef-growth enforce each other. This makes
reefs different from physically dominated sedimentary processes. In
reefs biological programs in multigeneration communities dominate the
sedimentation process, which demand and allow upward growth rather than
isotropic distribution. These principles are demonstrated in four case
studies. [part of extensive summary]</ABSTRACT>

85132 <TITLE>Paleocene 14. Organisms and carbonate substrates in marine
environments.</TITLE>
85133 <SOURCE>Geoscience Canada 19, 3: 97-112.</SOURCE>
85134 <ABSTRACT>Carbonate substrates are normally produced in situ by
organisms that live above, at or below the sediment-water interface;
that is they represent a relatively self-enclosed ecosystem. During the
last 3.5 billion years, there have been major cyclical variations in the
global carbonate sediment budget in the oceans, and organisms have
been, to a large extent, directly responsible for these variations. At
the substrate level, there is a direct interplay between the planktic
and nektonic organisms that occupy the watermass above, and the benthic
organisms that utilize the substrate as a food resource and domicile
below though these relationships depend more on grain size, nutrient in
the sediment, pore chemistry, and the general nature of the substrate
(texture, fabric, etc.) than it does on the mineralogical differences
between the siliciclastic or calcium carbonate composition of the
sedimentary grains. This synthesis is an attempt to look at both the
macrocosmos and microcosmos of organisms and the carbonate substrates
they occupy. It will exclude the reef and intertidal-subtidal microbial
mat environments, as well as terrestrial fresh water ecosystems. Trace
fossils will be treated only in passing because of their importance to
recognition of sediment cycling. Fossil organisms provide many clues to
the ancient marine environment, as their distribution is limited by
physico-chemical factors such as temperature light, substrate and
watermass chemistry (pH, Eh, solubles, salinity, etc.), gases
(oxidizing, reducing etc.) ambient physical energy, random or
predictable catastrophic effects (tides, storms, sea level change,
etc.), the nature of the substrate (hard, soft, mobile, static, smooth,
rough, grain size, etc.), and biological factors, such as their own

functional limitations and relationships to other organisms occupying the substrate. [original introduction] </ABSTRACT>

85145 <TITLE>Reef metabolism and endo-upwelling in perspective.</TITLE>

85146 <SOURCE>Coral Reefs 13, 4: 199-201.</SOURCE>

85147 <ABSTRACT>Rougerie and Wauthy (1993) have recently advanced the concept of endo-upwelling to explain high rates of metabolism for oceanic coral reefs and atolls. The principal hypothesis advanced in this and previous papers (Rougerie and Wauthy 1986, 1988; Rougerie et al 1992) is that geothermal heat deep within the basalt and limestone underlying Pacific island reefs, stimulates nutrient-rich Antarctic Intermediate Water at depths of several hundred meters to flow upward through the reef structure. The emergence of this nutrient-rich water in the shallow surface water of reefs is used to explain high rates of carbon fixation, commonly measured on reef flats. There are two problems with this hypothesis, one of a general nature, and one that is specific to the data presented: (1) productivity on reefs does not require a large supply of "exotic" nutrients and (2) the data on nutrient concentration of interstitial water are easily explained by the oxidation of organic matter within the reef structure and sediments. [first fragment of a polemical short paper] </ABSTRACT>

85158 <TITLE>Stratigraphic tests of cladistic hypotheses.</TITLE>

85159 <SOURCE>Paleobiology 21, 2: 153-178.</SOURCE>

85160 <ABSTRACT>Cladograms predict the order in which fossil taxa appeared and, thus, make predictions about general patterns in the stratigraphic record. Inconsistencies between cladistic predictions and the observed stratigraphic record reflect either inadequate sampling of a clade's species, incomplete estimates of stratigraphic ranges, or homoplasy producing an incorrect phylogenetic hypothesis. A method presented in this paper attempts to separate the effects of homoplasy from the effects of inadequate sampling. Sampling densities of individual species are used to calculate confidence intervals on their stratigraphic ranges. The method uses these confidence intervals to test the order of branching predicted by a cladogram. The Lophospiridae ("Archaeogastropoda") of the Ordovician provide a useful test group because the clade has a good fossil record and it produced species over a long time. Confidence intervals reject several cladistic hypotheses that postulate improbable "ghost lineages". Other hypotheses are acceptable only with explicit ancestor-descendant relationships. The accepted cladogram is the shortest one that stratigraphic data cannot reject. The results caution against evaluating phylogenetic hypotheses of fossil taxa without considering both stratigraphic data and the possible presence of ancestral species, as both factors can affect interpretations of a clade's

- evolutionary dynamics and its patterns of morphologic evolution.

85184 <TITLE>Mud mounds: a polygenetic spectrum of fine-grained carbonate
buildups.</TITLE>
85185 <SOURCE>Facies 32: 1-70.</SOURCE>
85186 <ABSTRACT>This research report contains nine case studies (part II to
X) dealing with Palaeozoic and Mesozoic mud mounds, microbial reefs,
and modern zones of active micrite production, and two parts (I and XI)
summarizing the major questions and results. The formation of different
types of in situ formed micrites (automicrites) in close association
with siliceous sponges is documented in Devonian, Carboniferous,
Triassic, Jurassic and Cretaceous mounds and suggests a common origin
with a modern facies found within reef caves. Processes involved in the
formation of autochthonous micrites comprise: (i) calcifying mucus
enriched in Asp and Glu, this type presumably is linked to the
formation of stromatolites, thrombolites and massive fabrics; (ii)
protein-rich substances within confined spaces (e.g. microcavities)
result in peloidal pockets, peloidal coatings and peloidal
stromatolites, and (iii) decay of sponge soft tissues, presumably
enriched with symbiotic bacteria, lead to the micropeloidal
preservation of parts of former sponge bodies. As a consequence, there
is strong evidence that the primary production of micrite in place
represents the initial cause for buildup development. The mode of
precipitation corresponds to biologically-induced, matrix-mediated
mineralization which results in high-Mg-calcites, isotopically balanced
with inorganic cements or equilibrium skeletal carbonates,
respectively. If distinct automicritic fabrics are absent, the source
or origin of micrite remains questionable. However, the co-occurring
identifiable components are inadequate, by quantity and physiology, to
explain the enhanced accumulation of fine-grained calcium carbonate.
The stromatolite reefs from the Permian Zechstein Basin are regarded as
reminiscent of ancestral (Precambrian) reef facies, considered the
precursor of automicrite / sponge buildups. Automicrite / sponge
buildups represent the basic Phanerozoic reef type. Analogous facies
are still present within modern cryptic reef habitats, where the

biocalcifying carbonate factory is restricted in space.</ABSTRACT>

- 85301 <TITLE>Long-term changes in the rotation rate of the Earth.</TITLE>
85302 <SOURCE>Earth. Sci. Rev. 9: 259-274.</SOURCE>
85303 <ABSTRACT>In the last decade, major advances in both observational and theoretical fields have taken place in our understanding of the rotation of the Earth. With the adoption of Atomic Time, the rotation rate can now be measured with unprecedented precision and independently of planetary or lunar motions. Information from earlier observations is also being recovered more accurately: independent analyses and new data from ancient eclipse observations have increased confidence in the controversial results obtained earlier. Perhaps the most outstanding development is the tentative measurement of the mean rotation rate in the remote geological past, made possible by the study of periodicities in the skeletal growth of fossil organisms. The improved data have exposed new geophysical problems and accentuated earlier ones. An unexplained acceleration of the Earth's rotation is confirmed by the re-examination of ancient eclipse records. In addition, Darwin's theory of tidal friction now has the arbitrariness of its time-scale replaced by data from modern astronomical observations so that, in spite of various theoretical refinements, it leads to the unacceptable prediction of a catastrophic period in the history of the Earth-Moon system in the mid-Precambrian. Information from the study of fossil growth increments can make a vital contribution in both these problems. The palaeontological data have been gathered mainly from corals and bivalves, although several other groups with accretionary skeletons provide a few figures and are potentially useful. The unexpected cosmogonic applications of these data have stimulated research into the physiological and particularly the ecological factors controlling incremental growth in these organisms, especially the bivalves. The main problems center on the recording accuracy and the definition of the growth increments. The difficulty of eliminating irregular interference and of recovering geophysically useful measurements from the fossil record is discussed and we have tried to assess the reliability of the information already derived from this source.

85314 <TITLE>Animal colonies-development and function through time.</TITLE>
85315 <SOURCE>Dowden, Hutchinson and Ross, Inc., Stroudsburg, Pennsylvania (overseas by wiley-Interscience).</SOURCE>
85316 <ABSTRACT>This volume brings together the views of zoologists and paleontologists specializing in the study of metazoan colonies. Contents include expanded versions of papers from the symposium on animal colonies held at the November 1971 meeting of the Geological Society of America and the Paleontological Society, as well as additional commentary and papers of a review nature which provide an overall perspective. The contributors examine the basic nature of metazoan colonies, review much of the existing literature, and offer new morphologic data from both fossil and modern animals. The papers present new information on the development and function of key groups of living and fossil colonial animals. New descriptive data permit evaluation of the concept of coloniality as applied to the Porifera, Coelenterata, Bryozoa and Hemichordata (Class Graptolithina). The fossil records of these phyla are used to document the evolution of the colonial habit. The text is extensively illustrated with 140 line drawings and over 200 photographs. 85328 <SOURCE>SEPM Special Publication 18; 256 pp.</SOURCE>
85329 <ABSTRACT>This is a series of generally excellent papers on several aspects of living and fossil reefs. "Articles by Bloom, Purdy, and Goreau and Land emphasize the significance of Pleistocene events in determining present day reef geometry"; Purdy's long paper (68pp) is especially notable in challenging some aspects of "Darwinian" theory on reef origin. He argues that "many, if not most, of the shape attributes of modern reefs are fundamentally karst-induced rather than growth-induced"; and provides a wealth of experimental and observational data to support his conclusions. The paper by Heckel (65pp) is a thorough and excellent review of reefs and "reefs" through geologic time. He discusses terminology and reef classification with emphasis on differentiating between description and interpretation. After a system by system review of "reefs" in the geologic record and of the major biological contributors to these structures, he discusses modern analogs and origins. The papers by Krebs and by Bosellini and Rossi summarize their studies of classic ancient reef complexes of central Europe. Matthews reviews and analyzes the complexities of diagenesis in recent and ancient "reefs". Contents of the symposium are as follows: * Geomorphology of Reef Complexes, by Arthur L. Bloom; * Reef configurations: Cause and effect, by Edward G. Purdy; * Fore-Reef morphology and depositional processes, North Jamaica, by Thomas F. Goreau and Lynton S. Land; * Carbonate Buildups in the Geologic Record: a Review, by Philip H. Heckel; * Devonian Carbonate Complexes of Central Europe, by Wolfgang Krebs; * Triassic Carbonate Buildups of the Dolomites, Northern Italy, by Alfonso Bosellini and Daniele Rossi; * A Process Approach to Diagenesis of Reefs and Reef Associated Limestones, by R.K. Matthews.</ABSTRACT>

85354 <SOURCE>Bulletin Centre Rech. Pau SNPA 7, 1: 171-176.</SOURCE>
85355 <ABSTRACT>Dans les récifs on peut observer deux sortes de cimentation: sous-marine et subaérienne. * Dans la cimentation sous-marine des récifs, l'aragonite et la calcite magnésienne oblitèrent progressivement les pores existants. Quand le pH devient élevé (approximativement 9,0-10,0) les grains de quartz, dans les récifs, sont remplacés par le CaCO₃ qui précipite aussi sous forme de ciment. Une telle augmentation du pH est un processus biologique. * Dans la cimentation subaérienne, l'aragonite des cristaux est progressivement dissoute dans les récifs qui se trouvent au-dessus du niveau de la mer. Cette dissolution continue jusqu'à ce qu'il ne reste que des enveloppes micritiques. Les enveloppes micritiques consistent originellement en calcite magnésienne mais elles deviennent de la calcite peu magnésienne pendant la diagénèse subaérienne. La dissolution de l'aragonite crée une porosité et une perméabilité extrêmement importante. La formation subséquente de la calcite sur les enveloppes micritiques réduit les vides des pores secondaires.</ABSTRACT>

85380 <SOURCE>SEPM Special Publication 18 [Leo Laporte (ed.): Reef in Time and Space]: 9-76.</SOURCE>
85381 <ABSTRACT>It has been generally assumed that the deep borings on Pacific atolls have confirmed Darwin's theory of coral reef development which holds that continued subsidence results in the successive appearance of fringing reefs, barrier reefs and atolls. It is certainly true that the considerable thicknesses of shallow water carbonates encountered in these core holes necessitates subsidence; however it does not necessarily follow that this subsidence has resulted in the genetic succession of reef types advocated by Darwin. It is the purpose of the present paper to enlarge on an alternate theory first presented by MacNeil, and in so doing to demonstrate that many, if not most, of the shape attributes of modern reefs are

fundamentally karst-induced rather than growth-induced. There can be little doubt that the carbonate platforms beneath most modern reefs have suffered some degree of subaerial exposure. This general inference is warranted by the apparent thinness of Holocene shallow water carbonate deposits in conjunction with the low stand of sea level during the Wisconsin glaciation. Thus it seems logical to conclude that most modern reefs have developed on a karst substrate. The occurrence of drowned sink holes a few hundred feet deep on several modern carbonate platforms supports the same conclusion and more importantly suggests a potential for the development of considerable solution relief. * Experiments with limestone blocks indicate the feasibility of solution development of the diagnostic cross-section morphology of both barrier reefs and atolls. Tropical karst landforms are suggestive of the same conclusion. All that is apparently required is a large surface area of gently dipping beds that is bordered on one or more sides by a relatively steep slope. The dissolving action of meteoric water differentially lowers the central area relative to that immediately adjacent to the steep slopes and results in a partially or completely rimmed solution basin. Subsequent rise in sea level permits coral colonization of both the solution rim and the residual karst prominences within the basin. The resulting barrier reef or atoll, with its satellite lagoon reefs, is thus formed without recourse to a prior history of reef development. The attributes of the reefs themselves support this interpretation. Special pleas have been advanced for many of these, but all seem related to the development of a karst solution basin. Thus, drowned "atolls" reflect drowned karst topography; reef passes originate as drainage breaches in the solution rim; faroes are a karst product of breaching; peripheral limestone islands are exposures of the fossil drainage divide; and spurs and grooves are expressions of lapies. These karst-induced differences in relief are perpetuated, and indeed accentuated, by reef growth, but reef growth per se has little to do with the basic configuration. </ABSTRACT>

85407 <ABSTRACT>During the International Sedimentological Congress of Heidelberg (Germany), the author - in collaboration with his colleague J. Pel of the University of Liege (Belgium) - has emphasized the

influence of the sedimentary rythm about the location of the stratiform ore deposits in some facies of the reef environment and has proposed a first synthesis of the relations between several stratiform deposits of varying mineralogy and different ages also associated with reef complexes. * In this paper, the author illustrates the sedimentological method used previously in resting principally on a comparative analysis of the ore conditions which characterize the stratiform lead zinc deposits of Reocin (Spain), Eastern Alps (Bavaria, Austria), Pine Point (Canada) and SE Missouri (United States).</ABSTRACT>

85420 <ABSTRACT>Bien que les principes généraux de la théorie de Darwin sur le développement récifal soient acceptés, l'auteur suggère que la configuration actuelle des récifs est surtout conditionnée par une morphologie karstique préexistante acquise par les plates-formes carbonatées durant la glaciation pleistocene. L'expérimentation confirme la théorie selon laquelle une plate-forme carbonatée exposée à la dissolution subaérienne se modifiera, à l'échelle régionale, pour donner une dépression centrale limitée par un ressaut bordier. A une échelle plus locale, la morphologie karstique est déterminée par le climat: les climats tropicaux donnent une topographie de karst conique tandis que les climats tempérés engendrent un paysage à dolines. Ces reliefs karstiques submergés tous d'une transgression ultérieure, influencent la géométrie de nouveaux récifs; les barrières récifales s'installent sur les ressauts bordiers tandis que localement des récifs de type patch se développent sur les parties hautes des karsts coniques.</ABSTRACT>

85432 <SOURCE>In G.C. Amstutz & A.J. Bernard (eds): Ores in sediments: 195-207; Berlin.</SOURCE>

85433 <ABSTRACT>Comparative analysis of Givetian reef complexes from Belgium and Aptian reef complexes from the Santander province in Spain displays an identical sedimentary rhythm. The study of the stratiform Reocin lead-zinc deposit, located in Aptian dolostones from this Santander province, has disclosed genetic relations between mineralization and location in the reef complex. These relations are dependent on the sedimentary rhythm. This observation affords a basis for comparing several stratiform deposits of varying mineralogy and different ages, also associated with reef complexes. Sedimentological analysis leads to an examination of other deposits related with peri-reef facies and eventually to a conclusion concerning the paleogeographical distribution of stratiform mineralization within reef complexes.

85758 <ABSTRACT>We regret to report the death in early June of Professor Jon N. Weber, geochemist, Pennsylvania State University. * Prof. Weber was born in Kitchener, Ontario, Canada in 1935, received his Ph.D. degree in geochemistry at Toronto (Ontario) in 1962, and taught at Penn State

from that time. * He published several papers on skeletal composition of Holocene corals and was studying various aspects of coral and reef growth and composition at the time of his death.</ABSTRACT>

85782 <TITLE>Nomenclatural status of taxa proposed as "varieties".</TITLE>
85783 <SOURCE>FC&P 06, 1: 14-15.</SOURCE>
85784 <ABSTRACT>Terms for subdivisions of species (variety, forma, mutant, subspecies) have been applied by paleontologists for many years without appreciable consistency. Commonly, a single taxon would be designated as a "variety", a "subspecies", or a "species" by workers with little regard for the rank assigned previously by others. The current International Code of Zoological Nomenclature is applicable to species-group taxa (i.e., species and subspecies), but it definitely excludes from availability and from formal zoological nomenclature (ICZN, Arts. 1, 15) those infrasubspecific taxa (i.e., varieties and formae) initially proposed after 1960. The essential equivalency, for practical purposes, of taxa cited as "subspecies ", "formae", "variety", etc. in older publications was recognized in the Code (ICZN, Art. 45), however, so that all these taxa proposed prior to 1961 (and otherwise available) are to be regarded and cited as "subspecies". It seems undesirable and incorrect to cite available pre-1961 names as "A-us b-us var. c-us " now rather than as "A-us b-us subsp. c-us". [] Objectively unavailable infrasubspecific taxa also cannot serve as type species for genus-group taxa. Genus-group taxa based on such "type species", therefore, are unavailable. Removal from consideration of a "designated" taxon having an unavailable name, however, may originally fix as type species (e.g., by monotypy) another taxon having an available name so that the genus-group name may retain availability. [initial and final parts of a nomenclatorial note]</ABSTRACT>

- 85927 <ABSTRACT>The need for the preparation of thin sections or acetate peels for the proper study of internal structures in corals and stromatoporoids is stressed. Type specimens of species in these groups which have not already been sectioned or peeled will ultimately require preparation for adequate revision. Curators are urged to allow such work to be done on type material in their care and a procedure is suggested to help them assess the need for preparation and to ensure that the original form of the specimen is adequately recorded. 86069 <SOURCE>FC&P 10, 2: 5.</SOURCE>
86070 <ABSTRACT>Prof. Dr. Karl Werner Barthel from the Institut f. Geologie und Palaeontologie der Technischen Universitaet Berlin, born 15 September 1928, died suddenly and unexpectedly on 13 October 1981. * His scientific field of work, filled with profound interest, was far-reaching. This is manifested in his numerous publications on various topics in stratigraphy and paleontology. Shortly before his death he was greatly involved in the organization of a Special Field of Research on "Geoscientific Problems in Arid Regions". * His inquiring mind induced him to occupy himself with a series of investigations on recent and fossil reefs. [abbreviated original note; accompanied by list of recent publications of Prof. Barthel] </ABSTRACT>

- taxonomy and biostratigraphy of Palaeozoic corals.</TITLE>
86108 <SOURCE>FC&P 10, 2: 16-30.</SOURCE>
86109 <ABSTRACT>The list contains information predominantly on deceased coral research workers; selection of items for each worker was guided by relative completeness or ease of access to journals or books mentioned. * The chief first source of information used for those deceased prior to 1938 was K. Lambrecht, W. & A. Quenstedt, Fossilium Catalogus I: Animalia, pars 72 Palaeontologia, Catalogus bio-bibliographicus, 1938, Dr. W. Junk, Gravenshage, in the 1978 reprint Edition by the Arno Press Inc., New York. * The University of Queensland Library did not receive its copy of W.A.S. Sargent's 1980 Geologists and the History of Geology, 5 vols, New York, Arno Press in time for use in this issue of Fossil Cnidaria. * My starting point for names to be selected was the list of references in the Treatise on Invertebrate Paleontology, Part F Supplement I Coelentarata, Anthozoa subclasses Rugosa, Tabulata, 2 vols., 1981, Geological Society of America and University of Kansas Press. [original introduction; the "list" contains 212 names, from Othenio Abel to Karl Alfred Zittel]</ABSTRACT>

86251 <SOURCE>FC&P 04, 1: 6-7.</SOURCE>
86252 <ABSTRACT>Charles W. Merriam was born on July 6, 1905 in Berkeley, California USA and died a few miles away on July 7, 1974, in Menlo Park. Between these dates, Merriam had a varied career as paleontologist and stratigrapher in several institutions. * Through most of the time, his principal interest was in the Paleozoic rocks and corals of the Great Basin and Pacific Coast provinces of the United States, although his early studies include important work on Tertiary fossils (most notably a monograph on Turritella). His Devonian publications began in 1934 and extended to the year of his death. At the time of his death, he had just completed a manuscript on Silurian and Devonian rugose corals from Southeastern Alaska. […] Merriam 's bibliography includes 42 titles. Listed below are those of interest to coral specialists. Specific studies of corals are marked with an asterisk (*); unmarked papers include significant observations on corals or their biostratigraphy. 86277 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 2.1-2.21.</SOURCE>
86278 <ABSTRACT>Une comparaison entre milieux terrestres que nous connaissons par notre vie quotidienne, et aquatiques qui nous sont étrangers, facilite la compréhension des processus vitaux responsables de la formation des récifs (Fig. 1). Les différences écologiques les plus importantes sur terre et en mer résident dans la viscosité différente

du milieu aérien dans lequel la vie terrestre évolue, et du milieu aquatique abritant la vie sous-marine. La viscosité aquatique a une multitude de conséquences directes et indirectes: (1) inertie relative du transport de substances dans le milieu aquatique et en particulier dans le sol; (2) restrictions des surfaces réactives dans le sol aux deux phases solides et fluides et restriction des modes possibles de réactions chimiques dans le sol par l'absence de la phase gazeuse; (3) importance physique des mouvements de l'eau souvent destructifs, limitant la vie; (4) absorption rapide de la lumière dans la colonne d'eau; (4) possibilité de se maintenir en suspens dans l'eau libre à peu de frais énergétiques (vie planctonique). * Les conséquences de ces quelques points (qui sont loin d'être exhaustifs) se reflètent dans la faible productivité relative du milieu aquatique et dans l'attrait vital du milieu terrestre dès que la quantité de l'eau transitant le système est suffisante. La différence de productivité terre - mer peut atteindre trois ordres de grandeur. [introductory chapter] </ABSTRACT>

86289 <TITLE>Mud-mounds: geology and palaeoecology.</TITLE>

86290 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 23.1-23.8.</SOURCE>

86291 <ABSTRACT>Mud-mounds are persistent carbonate build-ups ranging at least from Early Cambrian to Cretaceous and probably Recent times. Once interpreted as true ecological reefs built by "stromatolitic organisms", by bryozoans, stromatoporoids, etc., the recognition of the volumetric abundance of constitutive mud led many authors (Pray 1958; Lees 1964) to discard this interpretation. * Beside their considerable sedimentological and (micro-) palaeontological interest they are of great economic importance in terms of oil and ore deposits (lead-zinc). Their accretion appears to result from the superposition of sigmoidal muddy lenses eventually separated by clay seams or grainstone tongues of variable importance. This pattern may impart crude irregular bedding to the overall mound; in cases, stratification may be emphasized by alignment of lamellar organisms or of trains of fenestrae. Mud-mounds range from less than metric to hectometric dimensions in thickness and diameter; they may occur in fields of scattered mounds or coalesce laterally to form larger kilometeric banks. 86302 <TITLE>Carbonate diagenesis: selected examples of Cenozoic and Mesozoic reefs.</TITLE>

86303 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 27.1-27.18.</SOURCE>

86304 <ABSTRACT>Diagenesis starts directly after the formation or genesis of any skeletal grain. That means, for example, cementation occurs already

in living corals in those parts, which are not more covered by the living tissue. Most of the non-skeletal grains therefore are either the products of primary diagenetic effects, like ooids, grapestones, or micritized grains, or are reworked grains, already influenced by diagenesis, like bio- or lithoclasts. Hence no carbonate rock exists on earth, neglecting the age, which is not a product of diagenesis. * Three main diagenetic environments can be distinguished: (1) submarine diagenesis (marine phreatic) in shallow seas or in deeper parts of the oceans; (2) vadose diagenesis under the influence of rain water; (3) freshwater phreatic diagenesis below or in the water table. 86329 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 31.1-31.16.</SOURCE>

86330 <ABSTRACT>Les récifs fossiles intéressent les géologues pétroliers depuis près de 100 ans. Ils représentent en effet des réservoirs prolifiques pour les hydrocarbures et ont été parmi les premiers découverts (Cemsah en Egypte par exemple). * Si certains récifs ont été aisés à découvrir, soit en liaison avec des indices de surface, soit par leur situation structurale élevée, d'autres ne peuvent être décelés qu'après des études géologiques et géophysiques; et la difficulté même de ces études laisse encore ouverte la porte à de nouvelles découvertes ou à des extensions, même dans des bassins déjà explorés de façon intensive. C'est pourquoi l'industrie pétrolière accorde une importance particulière à la recherche sur les constructions récifales: modèles dans l'actuel, études paléo-écologiques de l'environnement, conditions de diagénèse,

- détection géophysique avec amélioration continue des méthodes seismiques, utilisation faciologique des diagraphies différées dans les sondages. [introductory fragments] </ABSTRACT>

- 86343 <ABSTRACT>Un certain nombre de gisements Pb-Zn sont localisés dans des formations récifales d'âge et de nature différents. Parmi les plus importants, citons: * dans le Cambrien de la plate-forme stable des USA, le district du Missouri Sud-Est (biohermes à stromatolithes); * dans le Dévonien du Canada, le district de Pine Point (barrière récifale à stromatoporoides et polypiers); * dans le Carbonifère d'Irlande, les gisements de Tynagh et Silvermines ("mud mounds" à stromatactis); * dans le Trias des Alpes orientales, les gisements de Salafossa, Raibl, Bleiberg, Mezica (plate-forme carbonatée ladino-carnienne interprétée par de nombreux auteurs comme un vaste complexe récifal); * dans le Crétacé du Nord de l'Espagne, le district de Reocin (complexe urgonien à rudistes et polypiers). * Ces exemples démontrent, en première analyse, l'importance des formations récifales en tant que roches encaissantes de concentrations plombo-zincifères. Ils indiquent aussi une certaine variété des organismes constructeurs et de la morphologie des appareils récifaux. * Cependant, sans vouloir simplifier à l'extrême, on peut dire qu'il n'existe pas de relations étroites entre la sédimentation récifale et la présence de minéralisations … [introductory fragments] </ABSTRACT>

86380 <TITLE>Taphonomy of reefs through time.</TITLE>

86381 <SOURCE>Topics in geobiology 32 [P.A. Allison et D.J. Bottjer (eds): Taphonomy: bias and process through time; 2nd Edition; Springer]: 375-409.</SOURCE>

86382 <ABSTRACT>Reefs are susceptible to multiple physical, chemical and biological taphonomic processes. Bioerosion, in particular has escalated through time and might be expected to have influenced the taphonomy of reefs. The following biases can be predicted: (1) In the absence of grain-reducing activities by reef biota (fish, echinoids, and clionid sponges) abrasion on Paleozoic reefs would have been dominated by physical processes and sediment grains may have been more coarse. (2) Increased bioerosion since the Jurassic is such that modern reefs are quickly reduced to rubble and sand leaving only the resilient branching corals and thick coralline algae. By contrast, many pre-Jurassic reefs commonly preserve intact, in situ frameworks that include massive or laminar, often soft-sediment-dwelling, growth forms. (3) After the appearance of reef fish in the Eocene, sediment production and distribution within reef complexes is likely to have increased markedly but this has not yet been fully elucidated. (4) Escalation in rates of bioerosion from the Miocene onwards are such that it can be expected that substantial aprons of reef-slope sediment may not have been present on pre-Miocene reefs. 86393 <TITLE>Roles of clone-clone interactions in building reef frameworks: principles and examples.</TITLE>

86394 <SOURCE>Facies [on-line first]</SOURCE>

86395 <ABSTRACT>In living and fossil reefs, rapid upward clone growth provides positive topographic relief; the skeletal framework provides rigidity. Clonal organisms have been the chief frame-builders during most of the Phanerozoic; large clone size, growth habit, growth form, and arrangement of these clones in the framework result from rapid growth rates. Dense skeletal packing enhances rigidity and results in live-live interactions between juxtaposed clones. These interactions are both heterospecific and conspecific; the former mostly involve spatial competition whereas the latter involve clone fusion, self-overgrowth and fission. We describe three types of fusion: a) inter-clone fusion of two or more clones, each from a separate propagule; b) intra-clone fusion of parts of the same clone having its origin from a single propagule; it includes recovery from partial clone

degradation and self-overgrowth; c) quasi-fusion between a live bud/polyp/zoooid and a dead part (stem; branch) of the same or a different clone, i.e. a live-dead association. [original abstract]

86420 <SOURCE>FC&P 14, 1: 4-14.</SOURCE>

86421 <ABSTRACT>Minato worked [in] diverse fields of geological sciences. His scientific achievements cover Quaternary geology and Neogene tectonism. Also, he engaged in petroleum exploration, ground water prospecting, land subsidence prevention and other aspects of applied geology. But his main field of research was Palaeozoic stratigraphy, palaeontology and geotectonics. He became interested in corals while he was mapping the Paleozoic strata in the Kitakami mountains in late 1930's. The Visean Onimuru limestone Formation there is particularly rich in coralline fossils. * He loved corals. Nearly one third of all his scientific writings are somehow connected with his coral studies, and include a monograph on the Japanese Carboniferous and Permian corals, a monograph on the family Waagenophyllidae, and his meticulous ontogenetical study on Gotlandian corals. [excerpts from the memorial; attached is a list of Minato's papers related to Paleozoic corals with 105 records, starting in 1941, ending in 1983]</ABSTRACT>

- 86447 <ABSTRACT>This is the first of three volumes. The books describes the phylogenetic system of modern organisms. Fossil organisms, as far as possible, are also included. The system of organisms is quite new and certainly much more adequate to the natural system than the old-fashioned one including two kingdoms of plants and animals. All orders including most families are thoroughly described and excellently illustrated by drawings. Latest scientific results are included. The morphology, anatomy, cytology, embryology, ontogeny, reproduction, life habitat, nutrition and behaviour, phylogeny and many other things are reported. * About 100 pages are dealing with sponges and about 200 with coelenterates. This important book represents a treasure of information. It can be recommended to every biologist and palaeontologist and should be available in every scientific library. - 86473 <ABSTRACT>Seit Juli 1984 läuft am Institut für Paläontologie der Universität Erlangen unter der Leitung von Erik Flügel ein von der Deutschen Forschungsgemeinschaft (DFG) gefördertes Forschungsprojekt "Evolution von Riffen". Dieses Projekt soll zunächst bis 1988 fortgesetzt werden. Im Rahmen dieser Untersuchungen wurden bisher bereits devonische, permische, triassische, jurassische sowie pleistozäne und holozäne Riffe und riffähnliche Strukturen (Mud Mounds, Reef Mounds) bearbeitet. Letztere werden im Folgenden jeweils unter den Begriff "Riff" subsummiert. Diese Arbeiten sind zum Teil abgeschlossen, ein anderer Teil wird fortgesetzt. Neu hinzu kommen kretazische und tertiäre Riffe. Arbeitsgebiete waren bzw. sind: Süddeutschland, Rheinisches Schiefergebirge, Ardennen, Dänemark, Alpen, Karpaten, Dinariden, Helleniden, Tunesien, Antiatlas, Montagne Noire, Rotes Meer, Kenia, Karibik, Florida, Texas, Mexiko. 86536 <TITLE>Jean Gabriel Lafuste (1930-1990).</TITLE>
86537 <SOURCE>FC&P 19, 2.1: 8a-8b.</SOURCE>
86538 <ABSTRACT>On the 1st of December 1990. Jean Gabriel Lafuste passed away in La Rochelle (France) […] Jean Gabriel was a man of principles - very many principles to which he arrived by his own original thinking. From the very beginning he rejected the idea to present a doctoral thesis. For him a person early in his career cannot suggest a valuable thesis. It should then be postponed towards the end of the career but by then most of the data is already published and discussed. Consequently a thesis is rather a waste of time. Poor Lafuste, he ran into considerable trouble because of this! On the other hand he insisted on perfectly documented and illustrated short clear notes which brought substantial new data. […] Jean Gabriel has revolutionized not only the study of tabulate corals by recognizing in

great detail a hierarchy of basic microstructural elements (microlamellae, lamellae, fibres) with a typical disposition and a transition in time characteristic of each genus, but also that of rugose corals where he discovered microstructural analogy. He contributed to microstructural comprehension in other groups of fossil and Recent organisms such as Archaeocyatha, Sponges Stromatopora, Bryozoans, Tentaculites and investigated also higher groups - cephalopods, fish scales and others. [excerpts from an obituary]

86627 <TITLE>John west wells 1907-1994.</TITLE>
86628 <SOURCE>FC&P 23, 1.2: 1-12.</SOURCE>
86629 <ABSTRACT>John's first publications (in 1930/32) were on scleractinian corals and these continued to be the main focus of his research; over half of his 175+ publications over the next 58 years addressed some aspect of scleractinian biology. He published regularly on Cenozoic and Mesozoic Scleractinia throughout his career, but not until 1950, coincident with his fieldwork at Arno Atoll, did he seriously begin to publish on Recent Scleractinia. His collaboration with T.W. Vaughan, on the "The revision of the suborders, families, and genera of the scleractinia" (1943a), is perhaps his greatest contribution to coral biology. This monograph was the first modern synthesis of the higher-level classification of the scleractinia (the next proceeding being that of Duncan in 1885) and is the basic reference for most coral workers. The monograph includes not only

diagnoses and keys to all the scleractinian higher taxa, but a summary of coral anatomy and morphology, reproduction, ecology, distribution, and evolution, and an extensive bibliography. This seminal work set the stage for wells' later account of the Scleractinia in the " Treatise on Invertebrate Paleontology" (1956d) and finally an updated list of all scleractinian generic and subgeneric names and their type species (1986b, 1987b). [excerpt from an obituary; attached is wells' portrait and a list of his publications (1930-1988)]

86654 <SOURCE>FC&P 24, 1: 24-25.</SOURCE>

86655 <ABSTRACT>Ausgehend von einem kritischen Rückblick auf die bisher im Schrifttum unterschiedlich verwendeten Termini zur Beschreibung bzw. Klassifizierung von Riffen wird eine erweiterte, auf dem jeweils dominierenden Interngefüge basierende, für alle fossilen Biokonstruktionen anwendbare Rifftypologie aufgestellt und anhand von Beispielen aus der Erdgeschichte veranschaulicht. Hierbei werden die sechs Biokonstruktionsgruppen skelettale wie non-skelettale Bioherme und Biostrome, Reef Mounds und Mud Mounds, zumeist mit mehreren Untergruppen, festgelegt und von non-rezifalen Bildungen abgetrennt. 86680 <SOURCE>FC&P 24, 2: 22-32.</SOURCE>
86681 <ABSTRACT>Huang [Jiqing] specialized in structural geology, geotectonics, petroleum geology, paleontology and stratigraphy. In the seventy years of his geologist's career, he published over 150 academic theses and 20 monographs. In his book "On Major Tectonic Forms of China", he first put forward the method of historical analysis to describe the subdivision of geotectonic elements, their characteristics and evolution, and established the polycyclic theory of tectonic movements, thus laid the foundation of historical geotectonic teaching in China. He established the theory of continental source beds of petroleum together with the theory of polystage reservoir rocks and insisted on the search for oil in East China when the famous Daqing Oil Field and others were discovered. [fragment of an obituary of Huang Jiqing (Huang T.K.); attached is a portrait of Huang Jiqing and a list of his 90 publications]</ABSTRACT>

86718 <TITLE>On the probability of [finding] ancestors in the fossil record.</TITLE>
86719 <SOURCE>Paleobiology 22, 2: 141-151.</SOURCE>
86720 <ABSTRACT>Three homogeneous models of species origination and extinction are used to assess the probability that ancestor-descendant pairs are preserved in the fossil record. In the model of cladogenetic budding, a species can persist after it branches and can therefore have multiple direct descendants. In the bifurcation model, a species branches to give rise to two distinct direct descendants, itself terminating in the process. In the model of phyletic transformation, a species gives rise to a single direct descendant without branching, itself terminating in the process. Assuming homogeneous preservation, even under pessimistic assumptions regarding the completeness of the fossil record, the probability of finding fossil ancestor-descendant pairs is not negligible. [initial part of an abstract; for full text see <http://www.jstor.org/pss/2401114>]</ABSTRACT>

86731 <TITLE>Fossil preservation and the stratigraphic ranges of taxa.</TITLE>
86732 <SOURCE>Paleobiology 22, 2: 121-140.</SOURCE>
86733 <ABSTRACT>The incompleteness of the fossil record hinders the inference of evolutionary rates and patterns. Here, we derive relationships among true taxonomic durations, preservation probability, and observed taxonomic ranges. We use these relationships to estimate original distributions of taxonomic durations, preservation probability, and completeness (proportion of taxa preserved), given only the observed

ranges. No data on occurrences within the ranges of taxa are required. When preservation is random and the original distribution of durations is exponential, the inference of durations, preservability, and completeness is exact. However, reasonable approximations are possible given non-exponential duration distributions and temporal and taxonomic variation in preservability. Thus, the approaches we describe have great potential in studies of taphonomy, evolutionary rates and patterns, and genealogy. [first part of an extensive abstract; for full text see <http://www.jstor.org/pss/2401113>] </ABSTRACT>

86745 <SOURCE>FC&P 26, 1: 2-4.</SOURCE>

86746 <ABSTRACT>On January 15th morning, Prof. Wu Wang Shi died at the hospital after a prolonged illness. * Wu Wang Shi was born in Wuxi, Jiangsu Province on July, 1931. She completed the university course at the University of Nanjing in 1954 and served in the Institute of Palaeontology, Academia Sinica, now the Nanjing Institute of Geology and Palaeontology, Academia Sinica (NIGPAC) till her death. In 1956, She took the graduate study on the Carboniferous and Permian corals in the Institute. Since then she had devoted herself in this field and in the Carboniferous and Permian biostratigraphy of South China till the end of her life. In 1984-1991, she had been committed to be the Director of the NIGPAC. She had been elected as the Chairwoman of the International Subcommission on Permian Stratigraphy and the Council Member of the International Association for study on Fossil Cnidaria and Porifera. * We lost not only an active and keen researcher on Paleozoic corals and biostratigraphy but also a friend. 86757 <TITLE>American Women and the Ph.D.</TITLE>

86758 <SOURCE>FC&P 26, 1: 16.</SOURCE>

86759 <ABSTRACT>My interest and memory were recently stirred by reading that Florence Bascom was the first woman to earn a Ph.D. in geology from an American institution; this in 1893 (Geotimes, November 1996, p. 12). Not so: Cnidarologists should know that the first was earned some five years earlier by a woman studying Paleozoic (mostly Devonian) corals. Mary Emilee Holmes earned a Ph.D. in paleontology from the University of Michigan in 1887 (Geotimes, November 1986, p. 11) or 1888 (Arnold 1977, Geology v.5, p.493). Holmes' thesis, The Morphology of the Carinae upon the Septa of Rugose Corals, was accepted by her Committee (Alexander Winchell and others) on June 20, 1887, and published that same year in Boston by Bradlee Whidden. According to Arnold, Holmes was the first woman Fellow of the Geological Society of America, elected in May 1889 (Bascom became the second woman Fellow in 1894). 86810 <SOURCE>FC&P 28, 2: 6.</SOURCE>
86811 <ABSTRACT>On the 22 of October 1998, in the city Orel (Russia), during the lecture talking in the Orel Pedagogic Institute, suddenly died famous palaeontologist, prominent investigator of Rugose Corals from Middle Asia, Doctor of Geological-Mineralogical sciences, Professor Alexander Lavrusevich. * Alexander was born at 18 January 1930 in Byelorussia. In 1941, on the beginning of the war between Germany and USSR together with his parents he was removed from Byelorussia to Tadjikistan. In 1948 he was entering and in 1953 was graduating the Department of Geology of Tadjik State University. After graduating from the University he worked in Tadjik Geological Government Department. On 1957 he began studing of Rugose Corals from Palaeozoic of Middle Asia. A.I. Lavrusevich reveal very big diversity of Rugose Corals from South Thian Shan. He collected, determited and described about 20000 patterns belonging to 250 species and 100 generas of Upper Ordovician, Silurian and Lower Devonian Rugose Corals from Central Tadjikistan. Alexander discovered and described 22 new genera of Rugose Corals: Amandaraia Lavrusevich, 1968; Chavsakia Lavr., 1959; Cruciphyllum Lavr., 1976, Cystipaliphyllum Lavr., 1964; Farabophyllum Lavr., 1971; Gissarophyllum Lavr., 1964; Heterophrentoides Lavr., 1991; Isfaraia Lavr., 1991; Ketophylloides Lavr., 1971; Maikotia Lavr., 1967 a.o. During 1966-1991 he worked in the Department of Geology of Tadjik State University. At 1991 he was leaving from Dushanbe to Orel and began to teach in the Orel Pedagogic Institute. Alexander Lavrusevich authored 60 scientific papers, many of them on corals. [original text]</ABSTRACT>

- 86876 <ABSTRACT>On January, 13th 2001 Dr. Manfred Grasshoff became 65 years old. Dr. Grasshoff worked at the Forschungsinstitut und Naturmuseum Senckenberg in Frankfurt/Germany. Two main fields of scientific work are his scope: Coelenterates and African spiders - both connected by research on evolutionary trends in these groups. Concerning corals, he is interested especially on recent gorgonarians - mainly of the Atlantic, the Red Sea and the Mediterranean but also of New Caledonia/Pacific. Moreover, of main interest are his studies of biological structures under the point of view of mechanical and

hydraulic functions of the animal body. He became well known by the signpost-like results. [short biographical note, accompanied by abbreviated list of Grasshoff's publications]

- 86967 <ABSTRACT>In the year 1811 Archduke Johann, the brother of Emperor Franz I, decided to open his combination of a teaching institution for natural-technical sciences and a museum in Graz. He brought his various collections from their former place of presentation, the castle of Schönbrunn in Vienna, as a very great and valuable start to the heart

of Styria. And he wanted only specialists for teaching and for the work in his collections. * So Friederich Mohs came to be the first teacher in mineralogy and the first curator of the mineralogical collection, at that time containing about 2500 objects, including minerals, rocks and fossils. The collection grew and Mohs invented the world-famous hardness-scale during his time in Graz. [introductory part of a short note]

87004 <TITLE>Early Ordovician stromatoporoid Pulchrilamina spinosa from South China: geobiological significance and implications for the Early development of skeletal-dominated reefs.</TITLE>
87005 <SOURCE>Paleontological Research 16, 1: 59-69.</SOURCE>
87006 <ABSTRACT>The thin, laminar to low domical, encrusting stromatoporoid Pulchrilamina spinosa is reported from the Tremadocian-Floian in Hubei and Guizhou provinces, South China. The Chinese Pulchrilamina appeared earlier (late Tremadocian-early Floian) than North American equivalents (early Floian), which possess large domical forms and are the main framework-builders. Pulchrilamina appeared much earlier than the observed diversification of other stromatoporoids. These skeletal

reef-builders thus provide excellent clues for understanding the initial evolution of the stromatoporoids and the subsequent development of the skeletal-dominated (especially stromatoporoid - dominated) reefs that reached their first acme in the late Middle-Late Ordovician.

87017 <TITLE>The skeletal geochemistry of the sclerosponge *Astrosclera willeyana*: Implications for biomineralisation processes and palaeoenvironmental reconstruction.</TITLE>

87018 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 313-314: 70-77.</SOURCE>

87019 <ABSTRACT>To investigate the controls on the geochemistry of aragonitic sclerosponge skeletons, we used secondary ion mass spectrometry (SIMS) to analyse an *Astrosclera willeyana* specimen. The high spatial resolution of SIMS allows the independent analysis of the two key crystal structures in the skeleton i.e. the fused spherulites (formed intracellularly and fused together at the surface of the skeleton) and the epitaxial backfill (deposited extracellularly at the base of the sponge tissue). We analysed Sr/Ca, Mg/Ca and Ba/Ca across a short (~5mm) transect of fused spherulites which represented several years growth. We observe cyclical variations (with a length of 0.1 to 0.6 mm in both Sr/Ca and Mg/Ca in some (but not all) sections of the transect. The observed ranges of Sr/Ca and Mg/Ca over the presumed seasonal cycles are ~9.5 to 11.5 mmol mol⁻¹ and 0.6 to 1.0 mmol mol⁻¹ respectively. The annual seawater temperature range at the study site is ~4.3°C, so the inferred temperature sensitivity of skeletal Sr/Ca and Mg/Ca is ~0.5 mmol mol⁻¹°C (or 5°C⁻¹) and ~0.1 mmol mol⁻¹°C (or 13°C⁻¹) respectively. This is higher than observed in most previous sclerosponge studies or anticipated from studies of synthetic aragonite. This indicates that the chemistry of the *A. willeyana* skeleton is affected by one or more additional influences, besides temperature, which are currently unresolved. The pH of the precipitating fluid, estimated from skeletal δ11B, is ~8.1-8.2 for both fused spherulites and epitaxial backfill. Epitaxial backfill contains significantly higher Sr/Ca, Mg/Ca and B/Ca and significantly lower Ba/Ca than the fused spherulites but Sr/Ca and Mg/Ca are positively correlated by the same relationship in both skeletal features. This suggests that the geochemistry of each feature is predominantly controlled by a common process. This is unlikely to be Rayleigh fractionation, which is indicated by negative correlations between Sr and Mg in aragonite.</ABSTRACT>

87030 <TITLE>Questioning the evidence of organic compounds called sponge biomarkers.</TITLE>

87031 <SOURCE>Palaeontology 56, 5: 917-925.</SOURCE>

- 87032 <ABSTRACT>Elevated concentrations of an organic compound, 24-isopropylcholestane, found in the Precambrian Huqf Supergroup of Oman may provide the oldest known sponge 'fossil'. This evidence is of critical importance for a properly balanced understanding of the origin of animals. Several different pelagophyte (class Pelagophyceae part of the Stramenopiles within the Chromaveolata) algae are also capable of producing these exact compounds, and may similarly have done so in deep time. Modern marine algae are also reported to produce structural isomers that are compositionally identical to the sponge marker; they do this in copious quantities. Further, 24-isopropylcholestane can be produced by diagenetic alteration of compounds produced in large quantities by algae. It is also possible that contamination by petroleum derived lubricating oil used when coring while extracting these compounds from subsurface layers, has affected the data. All extinct organisms that may have produced this compounds are unavailable for analysis by the modern organic chemist and cannot be eliminated from the list of possible producers of the sponge marker. There are also significant uncertainties regarding the dating of the strata from which these ancient compounds are found. Although the compounds are widely reported as c. 751 Ma, they are younger than 645 Ma. It seems more likely that these compounds represent algal biochemical evolution at a time when algal burial occurred in great quantity with well known coeval algal fossils but no sponge fossils. The macroalgal biomass may have declined during the agronomic revolution at the base of the Cambrian Period owing to processing by metazoans, accounting for the comparative scarcity of these sponge markers in Phanerozoic sediments, after which time sponge spicules and body fossils become evident.

- 87045 <ABSTRACT>In the paper are traced the development of some morphological features of Paleozoic and Mesozoic Stromatoporata (hydroid polyps). On the basis of evolution of astrorhizal elements is confirmed the status of this group in system of Hydrozoa . Paleozoic Stromatoporata and Mesozoic Sphaeractinoidea are equivalent representatives of class Hydrozoa, phylum Cnidaria. It is offered the new revised system of this group: 3 subclasses, 19 orders and 43 families are singled out. The 100 genera of Stromatoporata and Sphaeractinoidea are analyzed. Connections between Paleozoic Stromatoporata and Mesozoic Sphaeractinoidea hydroid polyps are considered. Morphology of a skeleton and progress of astrorhiza are analyzed. Relations of evolution of fossil hydroid polyps with maxima of tectonic-magmatic cycles are recognized. The centers of origin of fossil hydroids at the end of Baikal and the beginning Caledonian cycles have been connected with the Ural-Mongolian belt. Mesozoic Stromatoporata have been connected with the seas of Tethys ocean. For the determining of centers of origin and distribution is used the method of geohistorical biogeography.</ABSTRACT>

87056 <TITLE>Spicule structure and affinities of the Late Ordovician hexactinellid-like sponge *Cyathophycus loydelli* from the Llanfawr Mudstones Lagerstätte, Wales.</TITLE>
87057 <SOURCE>Lethaia 46, 4: 454-469.</SOURCE>
87058 <ABSTRACT>Exceptionally well-preserved specimens of the reticulose sponge *Cyathophycus loydelli* from the Sandbian (Late Ordovician) Llanfawr Mudstones Formation of Llandrindod, Wales, UK, have been examined using scanning electron microscopy (SEM). The specimens include exquisitely detailed pyritized spicules, and granular pyritization of surrounding soft tissues. Spicules frequently show axial canals of diameter similar to those of modern siliceous sponges, with hexagonal symmetry typical of modern demosponges rather than hexactinellids. In one case, the axial filament is also preserved. The largest spicules (ray diameter >20μm) show a complex structure, with a laminar external region similar to that of the extant hexactinellid *Monorhaphis*. Some spicules preserve sub-micron detail of the spicule surface, resembling the reticulate collagenous sheath of *Monorhaphis*. The hexagonal symmetry of the canal confirms that at least some Reticulosa are not crown-group hexactinellids, but stem-group Hexactinellida or Demospongiae, or stem-group Silicea. This suggests that a square canal is a sufficient diagnostic feature of total-group Hexactinellida, but that hexagonal canals were more widely distributed among Early Silicea and were probably not restricted to demosponges. Alternatively, comparison with the structure of modern verongioid fibres suggests that these may be homologous with the outer layers of *Cyathophycus* spicules, and *Cyathophycus* may instead be a stem-group demosponge. The preserved detail of the surface layer shows that pyritization can preserve certain material with extraordinarily fine resolution.</ABSTRACT>

87069 <TITLE>An enigmatic, possibly chemosymbiotic, hexactinellid sponge from the early Cambrian of South China.</TITLE>
87070 <SOURCE>Acta Palaeontologica Polonica 58, 3: 641-649.</SOURCE>
87071 <ABSTRACT>Six specimens of a strongly curved, cylindrical hexactinellid sponge have been recovered from the Tommotian-Attabanian Hetang Biota of South China, and are described as *Decumbispongia yuani* gen. et sp. nov. The robust, thick-walled sponge shows no evidence of an osculum or basal structures, and the body form is inconsistent with an upright, filter-feeding life position. Interpretations as a detritivore feeding by amoeboid extensions, or as a facultative chemosynthetic symbiosis of sponge and bacteria are considered. The latter interpretation is preferred due to the highly constrained body shape, and the body form is interpreted from this perspective. The species indicates that Cambrian sponges occupied at least some autecological niches that appear to have been vacant since that time.</ABSTRACT>

87082 <TITLE>Evidence for spicule homology in calcareous and siliceous sponges: biminerallic spicules in Lenica sp. from the Early Cambrian of South China.</TITLE>
87083 <SOURCE>Lethaia 45, 4: 463-475.</SOURCE>
87084 <ABSTRACT>The relationships of the extant sponge classes, and the nature of the last common ancestor of all sponges, are currently unclear. Early sponges preserved in the fossil record differ greatly from extant taxa, and therefore information from the fossil record is critical for testing hypotheses of sponge phylogenetic relationships that are based on modern taxa. New specimens of the enigmatic sponge Lenica sp., from the Early Cambrian Hetang Biota of South China, exhibit an unusual spicule structure. Each spicule consists of a siliceous core with an axial canal, an organic outer layer and a middle layer interpreted to have been originally calcium carbonate. This finding confirms previous work suggesting the existence of biminerallic spicules in early sponges. Combined with data from other early sponges, the new findings imply that the two fundamental spicule structures of modern sponges were derived from a compound, biminerallic precursor. Spicules are therefore homologous structures in Calcarea and Silicea, and if sponges are paraphyletic with respect to Eumetazoa, then spicules may also have been a primitive feature of Metazoa.</ABSTRACT>

87095 <TITLE>Stromatoporoid palaeoecology in the Frasnian (Upper Devonian) Belgian platform, and its applications in interpretation of carbonate platform environments.</TITLE>
87096 <SOURCE>Palaeontology 54, 4: 883-905.</SOURCE>
87097 <ABSTRACT>Stromatoporoid faunas in the Frasnian of southern Belgium are abundant in the carbonate platform environments present in this area. Stromatoporoids dominate the large skeletal organisms and occur principally in biostromes. The stromatoporoid assemblage is represented by a small number of taxa. Stromatoporoid genera include Actinostroma, Amphipora, Atelodictyon, Clathrocoilona, Salairella, Stachyodes, Stictostroma, Stromatopora and Trupetostroma which are present in environments ranging from the outer, outer intermediate, inner intermediate and inner zones and associated biostromes. Most large skeletal stromatoporoids are low profile, which reinforces the conclusions of previous studies that low-profile growth forms were the most successful stromatoporoid forms. These low-profile forms are likely to have been important sediment stabilisers that may have led to expansion of the carbonate factory. Growth forms vary between facies, indicating some degree of environmental control on form, for example, laminar in the intermediate zone, bulbous and domical in the inner and outer zones. Stromatoporoid taxa vary in occurrence across the environmental gradient from shallow to deep. There is some taxonomic control on growth forms, with some taxa showing more variability than

- others in different environments.</ABSTRACT>

- 87109 <SOURCE>Lethaia 44: 255-274.</SOURCE>
- 87110 <ABSTRACT>Stromatoporoids are the most abundant large skeletal organisms in middle Frasnian carbonate mound environments of southern Belgium. They occur in environments ranging from flank and off-mound, mound core, shallow mound and restricted mound. A detailed log and comprehensive sampling of stromatoporoids in a single section cutting through all middle Frasnian mound levels in La Boverie-Rochefort Quarry, near Rochefort and Dinant reveals a stromatoporoid assemblage comprising 10 genera, 472 samples, containing an overall total of 3079 stromatoporoids (including complete and fragmented specimens) have been studied. The following list gives abundance using numbers of specimens and areas of total stromatoporoid area on outcrop surfaces (% number, % area in cm²): Actinostroma (0.4, 9.2), Amphipora (15.5, 1.7), Atelodictyon (0.2, 4.4), Clathrocoilon (0.3, 0.5), Euryamphipora (13.7, 0.7), Idiostroma (2, 1.9), Salairella (1.2, 9.6), branching Stachyodes (43.2, 59.1), laminar Stachyodes australe (1.9, 1.3), Stictostroma (4.8, 13.1) and Trupetostroma (0.2, 0.8), showing that Stachyodes is approximately half of the total assemblage. Deeper environments contain more abundant low profile forms, shallow water facies contain more domical and bulbous forms, branching forms are ubiquitous. Low profile stromatoporoids are likely to have been important sediment stabilizers that may have led to expansion of the carbonate factory, and they may have therefore contributed to the structural building of the mounds. Stromatoporoid-coral intergrowths are observed in only Stictostroma suggesting that there is a close biological relationship between them, however, stromatoporoid skeletons in almost all cases appear to be unaffected by the presence of intergrown corals, suggesting they were commensals.</ABSTRACT>

87134 <TITLE>Earliest Pragian (Early Devonian) corals and stromatoporoids from reefal settings in the Cantabrian Zone (N Spain).</TITLE>
87135 <SOURCE>Geologica Acta 8, 3: 301-323; Barcelona.</SOURCE>
87136 <ABSTRACT>The oldest reefal episode in the Cantabrian Zone (earliest Pragian) consists of small biostromal patch reefs, mainly built by corals and stromatoporoids, and developed on a storm-dominated ramp. Four outcrops provide the stratigraphic framework in which these reef facies developed, and these permitted an interpretation of their depositional setting in terms of a relatively distal or protected shelf. We systematically describe three species of rugose corals, five species of tabulate corals, and six species of stromatoporoids. This fauna is allocated to three Pragian fossil associations. Association 1 is mainly composed of massive tabulate corals and stromatoporoids. Association 2 contains dominant branching rugose and tabulate corals. Finally, association 3 is represented by tiny massive tabulate corals. Each association occurs at a specific location within a framework of high-frequency deepening upward cycles, being related to a specific depositional setting. This mode of occurrence suggests that their development was tuned by relative base-level oscillations, forming during rises that took the sea-bottom to relatively deep or sheltered conditions, with rare reworking by storm-related currents. Finally, a comparison of this reefal fauna with examples of similar age from elsewhere is presented in order to explore their affinities.</ABSTRACT>

87147 <TITLE>The Sponge Family Guadalupiidae in the Texas Permian.</TITLE>
87148 <SOURCE>Journal of Paleontology 84, 5: 821-847.</SOURCE>
87149 <ABSTRACT>New and old species and genera of the family Guadalupiidae (spherulitic hypercalcified demosponges of the order Agelasida) are described or redescribed from the West Texas Permian. The entire family is reviewed and observations are made on the epibionts, growth patterns, functional morphology, ecological relationships, morphologic variability, modular structure, and evolutionary history of these largely reef-dwelling sponges. The stratigraphic distribution of species is also noted; many are limited and can define zones. The new genera Exovasa and Incisimura and the new species Guadalupia auricula, G. cupulosa, G. ramescens, G. microcamera, G. vasa, Cystothalamia megacysta, Lemonea simplex, Incisimura bella, and Exovasa cystauletoides are described. Almost all previously published taxa are redescribed and in some cases redefined. The Guadalupiidae are unique

among hypercalcified sponges in having a modular thalamid layer (thalamidium) covered on the exhalant surface by a non-modular stromatoporoid-like layer (trabecularium).</ABSTRACT>

87160 <TITLE>Records of a new spongelike group in the Riphean biota.</TITLE>
87161 <SOURCE>Paleontologicheskii Zhurnal 46, 3: 3-10.</SOURCE>
87162 <ABSTRACT>New microfossils of presumably sponge organization grade have been recorded in the Meso-Neoproterozoic boundary beds of the Riphean Lakhanda Formation (Maya River, Uchur-Maya Region, southeastern Siberia). Because of the microscopic size, they remained invisible for a long time among abundant green algae on the surface of individual acritarchs in associations with nematode-like organisms and zygotes and suspensors of fungal microfossils. The specimens were found during a reexamination of the type material of Annulusia annulata Timofeev et Hermann, 1979, fixed on biofilms. The biofilms have shown the presence of very small, abundant, colonial organisms represented by aggregations of cells tightly connected in a soft tissue structure. In morphological characters, mode of life, occurrence of spicule-like structures, symmetry of their body, with a central canal positioned at the apex and interpreted here as an osculum, they are considered to be similar to the sponges Demospongiae and Hexactinellida. The microfossils with a syncytium and collagen-fibrous network (amorphous body) resemble the sponge class Hexactinellida.</ABSTRACT>

87175 <ABSTRACT>The Archaeocyatha are a key group in several of the many discrete disciplines that together make feasible a valid history of the Earth: they are the oldest of the calcified sponges, the first metazoans to build reefs (in association with calcimicrobes), are characteristic fossils used for the biozonation of the first, pre-trilobitic Cambrian stage (Tommotian). To date, a valid key to their identification has not been available, so a tool for that purpose has been devised: it was created using the software XPER2, and is now available free, online. Published in English, the knowledge base includes the 307 valid described genera identified by 120 descriptors (85 morphological and ontogenetic, 8 stratigraphic and geographic and 27 taxonomic). A key to identification is supplemented by detailed descriptive cards with images of type specimens of each genus and details of their morphology that aid identification. [identification key is available at http://www.infosyslab.fr/archaeocyatha]</ABSTRACT>

87186 <TITLE>Evolution of Stromatoporoidea in the Ordovician-Silurian epicontinental basin of the Siberian Platform and Taimyr.</TITLE>
87187 <SOURCE>Russian Geology and Geophysics 51: 684-693.</SOURCE>
87188 <ABSTRACT>The paper discusses the evolution of Stromatoporoidea in the epicontinental sedimentary basin of the Siberian Platform and Taimyr during the Ordovician and Silurian. Specimens of the oldest genus, Priscastroma, were found in the middle of Middle Ordovician sediments. This genus is represented by the species P. gemina Khrom., which has two forms, A and B. Tracing the emergence of new genera over time, we identified two distinct branches in stromatoporoid evolution. The ancestor of the first branch is P. gemina f. A, which gave rise to the genus Cystostroma. The latter is the ancestor of two subbranches with predominant horizontal skeletal elements. The subbranches differ only in tissue microstructure. The genera Stromatocerium, Dermatostroma, and Aulacera display dense fibrous microstructure, whereas the genus Rosenella and its descendants display dense microstructure. The genus Lophiostroma, with a lamellar-fibrous tissue, may be a dead branch of evolution. The ancestor of the second branch is P. gemina f. B, which gave rise to the genus Labechia and its descendants. This branch has a dense tissue, with predominant vertical skeletal elements. Ordovician stromatoporoids from Siberia were compared with those from other basins of the world. Comparison shows that all the Ordovician genera from the epicontinental basin of the Siberian Platform and Taimyr originated here. Thus, this basin was one of the centers of stromatoporoid origin.</ABSTRACT>

87199 <TITLE>Pragian (Lower Devonian) stromatoporoids and rugose corals from Zujar (Sierra Morena, southern Spain).</TITLE>
87200 <SOURCE>Geologica Belgica 15, 4: 226-235.</SOURCE>
87201 <ABSTRACT>The locality Zujar at the boundary between the Badajoz and Cordoba provinces belongs to the Obejo-Valsequillo-Puebla de la Reina Domain. Within the fossiliferous reefal carbonates of Pragian age cropping out in Zujar, 10 stromatoporoid species and 7 rugose coral species are identified. The new rugose coral species Martinophyllum miriamae n. sp. is described. Hexagonaria soraufi Rodriguez Garcia, 1978 is a subspecies of Martinophyllum ornatum Jell & Pedder, 1969. The Pragian fauna of Zujar is a typical fauna of the Old world Realm with remarkably close relationships to Arctic Canada and Australia. Most species have been recorded for the first time from Spain. No significant relationships to the Eastern Americas Realm are visible. Remarkable is, that none of the stromatoporoid species of Zujar is known from the famous Pragian reef complex of Koneprusy in Bohemia, meanwhile the rugose coral fauna (e.g. Joachimastraea barrandei Galle, Hladil & May, 1999) shows some relations. Some of the species found are ancestors of important constructors of the Middle

- Devonian reef complexes, demonstrating that the roots of the Givetian-Frasnian reef complexes reach down to the Pragian.</ABSTRACT>

- 87214 <ABSTRACT>Newly collected phosphatised hexactinellid sponges are recorded from upper Cenomanian strata in the villages of Nezvys'ko and Rakovets' of Podillia, south-west Ukraine. Sponges from Nezvys'ko were first described in the late 19th century by Emil H. Dunikowski, but the original specimens appear to have been lost. Five neotypes of the hexactinellids *Laocoetis maxima*, *Callodictyonella regularis*, *Plocoscyphia podolica*, *Toulminia polonica* and *Leiostracosia crassa* are here designated. In addition, diagnoses of all species are provided and descriptions emended and supplemented.</ABSTRACT>

- 87239 <SOURCE>Facies 57, 4: 663-693.</SOURCE>

- 87240 <ABSTRACT>Norian reef boulders, exposed in a locality near the fountain "Tavuk Cesme" ("Chicken Fountain") in Taurus Mountains, southern Turkey yielded a large number of hypercalcified sponges, including "sphinctozoans", "inozoans", "spongiomorphids", and "chaetetids". The sphinctozoans from this locality are described in this paper. Geologically, this locality belongs to the Anamas-Akseki autochthonous. The reef boulders of this locality are exposed near the "Tavuk Cesme" fountain, located at the road, leading from the town of Aksu to Yenisarbademli. The following taxa are described: *Amblysiphonella taurica* nov. sp., *Anthalythalamia riedeli* Senowbari-Daryan, *Calabrisiphonella sphaerica* nov. sp., *Calabrisiphonella cuifi* nov. sp., *Cinnabaria minima* Senowbari-Daryan, *Colospongia recta* nov. sp., *Colospongia* sp. 1, *Colospongia* sp. 2, *Colospongia* sp. 3, *Cryptocoelia compacta* nov. sp., *Cryptocoelia?* sp., *Deningeria crassireticulata* Senowbari-Daryan, Zuhlke, Bechstadt and Flugel, *Discosiphonella minima* Senowbari-Daryan and Link, *Gigantothalamia ovoidalis* Senowbari-Daryan, *Hajarispongia dipoyrazensis* nov. sp., *Hajarispongia cortexifera* nov. sp., *Kashanella irregularis* Senowbari-Daryan, *Kashanella cylindrica* nov. sp., *Parauvanella ferdowsensis* Senowbari-Daryan, *Parastylotthalamia cylindrica* nov. gen., nov. sp., *Asiphothalamia polyosculata* nov. gen, nov. sp., *Sollasia norica* nov. sp., and *Thaumastocoelia sphaeroida* Senowbari-Daryan. The most abundant sponge is *Amblysiphonella taurica* nov. sp. followed by *Hajarispongia dipoyrazensis* nov. sp., *Colospongia* and *Discosiphonella minima* Senowbari-Daryan and Link are also relatively abundant. The stylotthalamid sponge *Parastylotthalamia* nov. gen. is an abundant sponge genus in other Norian reefs of the Taurus Mountains, but is rare at the "Tavuk Cesme" locality.</ABSTRACT>

87278 <SOURCE>Journal of Paleontology 85, 1: 48-57.</SOURCE>
87279 <ABSTRACT>Laocoetis piserai n. sp. (Hexactinellida, Porifera) from the mid-Cretaceous (i.e., Albian-Cenomanian) of James Ross Island is the first record of a fossil sponge from Antarctica. This new occurrence of a formerly widespread genus was restricted to relatively deep waters on the margins of an active volcanic arc. Its occurrence in Antarctica is further evidence that the genus Laocoetis underwent a dramatic reduction in its geographic range through the Cenozoic. The only living species of the genus at the present day is Laocoetis perion from Madagascar.</ABSTRACT>

87304 <SOURCE>Geologica Belgica 15, 4: 236-244.</SOURCE>
87305 <ABSTRACT>Taxonomic inconsistencies between two published collections of Devonian stromatoporoids were examined. The studied collections contain stromatoporoids sampled from the Middle and Upper Devonian from the Ardennes (collection by Lecompte) and the Holy Cross Mountains (collection by Kazmierczak). The study was limited to stromatoporoid species that were assigned to the order Stromatoporellida. At least eight species which were described from the Devonian of both the Ardennes and the Holy Cross Mountains should be revised: F. ruedemanni, H. crassum, H. porosum, H. perseptatum, S. lensiforme, S. socialis, T. laceratum, T. pingue. Specimens that were assigned to C. damnoniensis, C. spissa, H. episcopale, H. schlueteri, P. celluloseum and S. huronense do not need to be revised. The inconsistencies may severely influence

- the outcome of palaeogeographic and biodiversity studies, since the error is not distributed randomly among stratigraphic intervals and it affects classification at the genus-level.</ABSTRACT>

87316 <TITLE>The limited value of traditional morphometric features in stromatoporoid taxonomy.</TITLE>
87317 <SOURCE>Palaeontology 56, 5: 947-959.</SOURCE>
87318 <ABSTRACT>The morphological variation of stromatoporoids, which are solitary organisms, is partitioned into its presumably genetic and environmental components. Potentially heritable, environmentally mediated and residual components of morphological variability were estimated in a test set containing Devonian stromatoporoids of the genus Geronostromaria from southern Poland using analysis of variance. The taxonomic importance of traditional morphometric features is limited, because they are dominated by the intra-skeletal component of variance. Conventional metrics were therefore replaced by stereological and textural quantities. Both stereological and textural features are dominated by the inter-skeletal and inter-locality components of variation and thus may be valuable in taxonomic and environmental studies of stromatoporoids. Statistical analyses of these characters (principal component analysis and cluster analysis) were performed. Of 13 characters considered most useful in taxonomic studies, only five have been used previously in conventional species definitions.</ABSTRACT>

87330 <SOURCE>Acta Palaeontologica Sinica 51, 2: 222-237.</SOURCE>
87331 <ABSTRACT>Archaeocyatha (Porifera) were an important group of marine sessile organisms during the Cambrian, they evolved rapidly and were globally distributed during the Early Cambrian. They are therefore important for biostratigraphic correlation over large areas, nationally and internationally. In this paper we review and discuss developments in classification and ideas of relationships in the Class Archaeocyatha, particularly the work of Debrenne et al. (2002). we highlight the need for a cladistic approach in attempting to further clarify changing ideas about phylogenetic relationships. In terms of biostratigraphy and palaeogeography, the archaeocyaths of the Atdabanian, Botoman, and Toyonian Stages are particularly useful for Early Cambrian stratigraphic correlation and palaeobiogeographic analysis. We summarize the history and current status of research on archeocyathan systematic, biostratigraphic, and palaeogeographic distribution within China, as well as internationally, and identify important foci of interest for further work - most notably that they formed an important component of the Lower Cambrian carbonate fauna of the Yangtze Platform.</ABSTRACT>

87355 <TITLE>First fossil record of parasitism in Devonian calcareous sponges
(stromatoporoids).</TITLE>
87356 <SOURCE>Parasitology 138, 1: 132-138.</SOURCE>
87357 <ABSTRACT>* Introduction. Palaeozoic calcareous sponges
(stromatoporoids) are common bio-constructing fossils, they are
sometimes found in association with helicoidal structures of unknown
biological affinities. The interaction between the tube-forming
organisms has usually been classified as commensalism. ** Methods.
About 260 stromatoporoid skeletons from the Middle Devonian (Givetian)
of the Mont d'Hairs section near Givet (Champagne-Ardenne, France) were
thin-sectioned and analysed under transmitted light. *** Results.
Approximately 10% of the examined stromatoporoids (mainly belonging to
the genera Actinostroma, Stromatopora and Stromatoporella) contain
tubes classified as Torquaysalpinx sp. The Torquaysalpinx organisms
penetrated the skeletons of stromatoporoids in vivo (as evidenced by
skeletal overgrowths), around the infesting organisms, growth bands are
bent down. **** Conclusion. Diminished growth rates around the
infesting organism demonstrate a negative influence on the host,
similar to that seen in the modern demosponge-polychaete association of
Verongia-Haplosyllis. This is demonstrated by changes in growth bands.
As in the above-mentioned association, the endosymbiont might have been
feeding directly upon the tissues of the host. The Torquaysalpinx
organisms were gaining habitat and possibly also food resources - for
them this interaction was clearly positive. This long-term association
can therefore be classified as parasitism. This is the first evidence
for parasitism in Palaeozoic sponges.</ABSTRACT>

87368 <TITLE>Habitats of colonial rugose corals: the Mississippian of western
Europe as example for a general classification.</TITLE>
87369 <SOURCE>Lethaia 43: 558-572.</SOURCE>

- 87370 <ABSTRACT>Colonial rugose corals are a major constituent of shallow-water marine benthic communities in Mississippian times. The study of western European rugose coral habitats from the base of the Tournaisian stage to the Serpukhovian stage allows the recognition of four basic habitat types, which can be divided into a total of 11 subtypes. The classification is mainly based on field data, and thus rapidly applicable. Level-bottom communities in which large colony distances are characteristic (type A) represent the most basic community type, polyspecific (subtype A1) and monospecific (subtype A2) subtypes occur. Reduced colony distances result in the formation of coral meadows (type B), which either show homogenous coral distribution (subtype B1) or the development of patches (subtype B2). Coral biostromes (type C) represent a spectrum between hydrodynamically controlled biostromes (nothing in place, subtype C1) and biologically constructed and controlled biostromes (subtype C2). The bulk of the biostromes represent mixtures of those two subtypes (subtype C3). Colonial rugose corals are widely encountered in Mississippian bioherms where they are dwellers (subtype D1), form capping beds (subtype D2), support framework building along with other organisms (subtype D3) and form coral framework (subtype D4). The latter is probably the most uncommon of all subtypes in Mississippian times. The classification is widely applicable to other groups.</ABSTRACT>

- 87381 <TITLE>Alborziphyllinae, a new Late Devonian Rugose corals subfamily.</TITLE>
- 87382 <SOURCE>Journal of Sciences, Islamic Republic of Iran 21, 2: 131-136; Tehran.</SOURCE>
- 87383 <ABSTRACT>Members of the family Laccophyllidae are small, solitary rugose corals with stratigraphic ranges from Silurian to Permian. Among the laccophyllids, axial ends of major septa are united in an aulos and dissepiments may be absent or present. Minor septa can be contratingent and sometimes are small or in some genera are absent. Septa and aulos may be thick or thin. In this study, Famennian rugose corals of the Khoshyeilagh Formation in the north of Meyghan village (35 km NE Shahrood, Eastern Alborz) have been investigated for the first time. All the studied corals share their common characteristics with family Laccophyllidae. Convincingly, based on comparison of the presence of some key features among the collected samples with characteristics of existed subfamilies of laccophyllids, establishing a new subfamily can be essential. The Alborziphyllinae (new subfamily) encompasses a Late Devonian laccophyllid lineage. The new subfamily described here includes a new genus, Alborziphyllum and two new species, Alborziphyllum ferdowsiense and Alborziphyllum lonsdaleiforme.</ABSTRACT>

- 87395 Catactotoechus instabilis from the Lower Devonian of Morocco.</TITLE>
<SOURCE>Acta Palaeontologica Polonica 57, 2: 391-400.</SOURCE>
- 87396 <ABSTRACT>This study focuses on the life strategies of small, dissepimented rugose coral Catactotoechus instabilis (representative of Cyathaxonia fauna) from the Emsian argillaceous deposits of mud mounds of Hamar Laghdad (Anti-Atlas, Morocco). Numerous constrictions and rejuvenescence phenomena as well as frequent deflections of growth directions among the studied specimens suggest unfavourable bottom conditions resulted from sliding down of the soft sediment on the mound slopes. Dissepimental structures observed on well-preserved calices and thin sections played an important role in the life of the coral, supporting their successful recovery after temporary burial within unstable soft sediment. The development of lonsdaleoid dissepiments, apart from being biologically controlled, was also strongly influenced by environmental factors. Such modifications in lonsdaleoid dissepiments growth were observed in phases of constrictions, rejuvenescence and deflections of growth, when their development was significantly increased in comparison to phases of their stable growth. Dissepiment morphology suggests that the process of formation of lonsdaleoid dissepiments in Catactotoechus instabilis is consistent with the hydraulic model.</ABSTRACT>

- 87408 <SOURCE>Lethaia 45, 1: 24-33.</SOURCE>
- 87409 <ABSTRACT>In the fossil record, evidence for true epizoans, i.e. living animals inhabiting other living host-animals, is rather rare. A host reaction is usually needed to proof the syn vivo-settling of the epizoan. Herein, we provide a first report of such an epizoan biocoenosis from various strata of the Early Devonian of Hamar Laghdad, the world-renowned Moroccan mud-mound locality. In this case, solitary rugose corals settled as larvae on crinoid stems, perhaps at a spot where the epidermis was missing for some reason (injury, disease). Both the crinoid and the coral began to grow around each other. By doing so, the affected crinoid columnals formed a swelling, where ultimately only an opening slightly larger than the coral orifice remained. We discuss both macroecological and small-scale synecological aspects of this biocoenosis. The coral profited from its elevated home because it reached into more rapid currents providing the polyp with more food than at the densely populated seafloor, which was probably covered by a coral-meadow around the mounds and hydrothermal vents.</ABSTRACT>

- 87421 <SOURCE>Geologica Belgica 15, 4: 245-253.</SOURCE>

- 87422 <ABSTRACT>The monotypic genus Hamaraxonia gen. nov., with type species Hamaraxonia africana sp. nov., is described, based on only four specimens, from the middle Eifelian (top Costapolygnathus costatus Zone to basal Tortodus australis Zone) of the Hamar Laghdad, Anti-Atlas, SE-Morocco. In its prominent axial boss and dissepiments in maturity, the new genus is unique among pre-Carboniferous ahermatypic Rugosa. It is classified within the still polyphyletic subfamily Columnaxoniinae Weyer, 1980 of the family Cyathaxoniidae Milne-Edwards & Haime, 1850 (suborder Cyathaxoniina Spasskiy, 1977). Possible ancestors will probably be found among the neighbouring subfamily Laccophyllinae Grabau, 1928. For the moment, a phylogenetic line: Laccophyllum Simpson, 1900 > Hamarophyllum Berkowski, 2004 > gen. nov. pro Cyathaxonia hercynica Roemer, 1855 (Weyer & Zagora, 1990) > Hamaraxonia gen. nov. may be proposed, pending further records from other regions and additional intermediate taxa. The commonly used term columella (aseptal origin) and the nearly forgotten term pseudocolumella (septal origin) are redefined in the already morphogenetic sense of their authors (Milne-Edwards & Haime 1848) by selecting morpho-terminological types: Cyathaxonia cornu Michelin, 1847 (late Tournaisian), and Clisiophyllum keyserlingi M'Coy, 1849 (middle/late Viséan).</ABSTRACT>

- 87433 <TITLE>Devonian Corals of the Yarrol Province, eastern-central Queensland.</TITLE>
- 87434 <SOURCE>Memoir of the Association of Australasian Palaeontologists 38: 1-191.</SOURCE>
- 87435 <ABSTRACT>The Yarrol Province in eastern-central Queensland contains rocks ranging from latest Silurian to Permian. Devonian corals are locally abundant within the Yarrol Province, but their preservation is typically poor compared to the well known Carboniferous coral faunas of this Province and except for the Mount Etna coral fauna, the Devonian corals have not been systematically described. Early and Middle Devonian corals have been known from the Yarrol Province for a long time, even though they have never been properly described. As a result of this study it is now known that a fairly diverse Late Devonian coral fauna is also present, and this is the first Late Devonian coral fauna identified in Queensland. Overall, this study has identified seventy-seven species of coral referable to forty-five genera. Seventeen of the species are new: Tryplasma? careoseptum, T? abyssum, Aphyllum simplexum, Cystiphyllodes immanum, Breviphyllum mirourum, Smithiphyllum petercollsi, S. finseni, Papiliophyllum jelli, Disphyllum castellum, D. stupendum, Temnophyllum kroombitense, T. stainesi, Squameofavosites craigileei, Alveolites murrayi, Heliolites amplusa, H. comminus and Multithecopora tubus. Eighteen species have been left in open nomenclature due to insufficient material or poor preservation, and the remainder have been placed into forty-two previously described species. The corals have been divided into six faunas, with three faunas in the Early Devonian, two in the Middle Devonian, and one in the Late Devonian. These are the Taragoola, Holly, Armagh, Hopeful, Beschs and Kroombit faunas respectively. The Early Devonian faunas share some of the common corals, such as Heliolites daintreei, but do not show any strong affinities with other Early Devonian coral faunas around Australia. The Middle Devonian Hopeful Fauna contains only a small number of species. The Givetian Beschs Fauna was diverse and many

of the species are well known from eastern Australia, though it has few colonial rugose corals compared to most other Givetian faunas in Australia. The Kroombit Fauna is less diverse than other described Late Devonian faunas in the Canning Basin of Western Australia and Mostyn Vale Formation in New South Wales, and it shares only a few species with them. The distribution of corals such as *Alveolites murrayi* were very useful in mapping the Late Devonian rocks of the Yarrol Province.

87447 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de Belgique, Sciences de la Terre 81: 27-53.</SOURCE>

87448 <ABSTRACT>Nine taxa of rugose corals collected by le Maitre (1934) and coming from the Chalones Formation of the Southeastern Armorican Massif in France have been revised. They belong to the genera *Stringophyllum* wedekind, 1922, *Sociophyllum* birenheide, 1962, *Acanthophyllum* dybowski, 1873, *Beugniesastraea* Coen-Aubert, 1989 and *Fasciophyllum* Schlüter, 1885. Among this material, *Stringophyllum acanthicum* (Frech, 1885), *Sociophyllum elongatum* (Schlüter, 1881), *Acanthophyllum vermiculare* (Goldfuss, 1826) and *A. tortum* (Tsien, 1969) occur close to the Eifelian-Givetian boundary, on the south side of the Dinant synclinorium in Belgium. Moreover, the first three species have been defined in the Middle Devonian of the Eifel Hills in Germany and they are observed in the Late Eifelian and the Early Givetian of this area. For comparison, *A. heterophyllum* (Milne-Edwards & Haime, 1851) and *Sociophyllum* cf. *elongatum* sampled by le Maitre (1934) in the Late Emsian Valet Formation from the Southeastern Armorican Massif have also been investigated. The Belgian material of *Stringophyllum acanthicum* is included in the systematic description of this taxon.

87486 <SOURCE>Palaeontology 54, 6: 1435-1454.</SOURCE>
87487 <ABSTRACT>A rich and diverse coral fauna collected from the Livian (Visean, Mississippian) of Zonguldak and Bartin (North-western Turkey) contains numerous specimens of Dorlodotia and related forms. The most common species, D. delepinei Charles, 1933, is redetermined as Dorlodotia briarti, an European species. A new species of Dorlodotia is described for very large, phaceloid forms: D. euxinensis. The genus Ceriodotia is created for species close to Dorlodotia with a cerioid habit. It comprises two species: C. bartinensis and C. petalaxoides, both common in the Visean of Zonguldak and Bartin. Based on comparison of morphological characters and features of the astogeny, a phylogenetic lineage is proposed for Dorlodotia and the new taxa. The evolution of D. euxinensis from D. briarti is peramorphic. Subsequent paedomorphosis resulted in the lineage D. euxinensis - C. bartinensis - C. petalaxoides. Ceriodotia probably includes Visean taxa from Asia previously described as 'Acrocyathus'.</ABSTRACT>

- 87500 <ABSTRACT>The microbial-sponge-bryozoan-coral bioherm of Kongul Yayla in the Central Taurides (South Turkey) contains a rich and diversified fauna. Sponges and rugose corals are of particular interest. The most common taxa are Siphonodendron irregulare, S. pauciradiale, S. cf. intermedium, Lithostrotion araneum, L. decipiens, L. maccoyanum, Axophyllum aff. pseudokirsopianum, Palaeosmia multiseptata, P. murchisoni, Clisiophyllum aff. keyserlingi, Amygdalophyllum sp., Rotiphyllum cf. densum, Amplexocarinia aff. cravenensis, Soshkineophyllum? sp. and Espielia tauridensis sp. nov. newly described here. The tabulate corals are mostly micheliniids, syringoporids, cladochonids and auloporids. Heterocorals and chaetetids are also present. Siphonodendron pauciradiale and Lithostrotion maccoyanum are the guide taxa for the RC7ß biozone and indicate an late Asbian age for the bioherm. Facies and coral assemblage argue for a South-European affinity of the Kongul Yayla reef and probably for the whole Anatolian terrane.</ABSTRACT>

- 87512 <SOURCE>Geologica Belgica 15, 4: 273-283.</SOURCE>
- 87513 <ABSTRACT>After the late Frasnian extinctions, the rugose corals slowly recovered during the Lower and Middle Famennian (crepida to marginifera conodont zones) in southern Belgium and northern France (Avesnois) (Namur-Dinant Basin). Six genera represented by seven species are recognized and described here, one species (Breviphrentis superstes) is new. The rugose coral fauna described herein includes small solitary forms belonging to the so-called Cyathaxonia fauna and is similar or very close to those previously described within the same stratigraphic interval in Australia, China and Germany. It also contains a large species belonging to the genus Breviphrentis which was considered as extinct since the end of the Givetian (Middle Devonian) ("Lazarus taxon"). The tabulate corals from the Lower and Middle Famennian of this area, mainly represented by auloporids, are also briefly discussed. Rugosa only constituted a minor part of the fauna after the end-Frasnian crisis in the Namur-Dinant Basin contrary to the brachiopods, which were abundant and relatively diversified, and no rugose corals have been recovered from the early Lower Famennian (triangularis Zone). The first important Famennian coral radiation only took place during the Latest Famennian (Strunian).</ABSTRACT>

- 87525 <SOURCE>Journal of Paleontology 86, 6: 979-995.</SOURCE>
- 87526 <ABSTRACT>The oldest known Carboniferous rugose coral fauna in the Canadian Arctic Islands was collected in the Yelverton Inlet area of

northern Ellesmere Island, from Bashkirian carbonates of the lower Nansen and Otto Fiord formations. It includes the genera *Dibunophyllum* Thomson and Nicholson, *Lonsdaleia* McCoy, *Palaeosmia* Milne-Edwards and Haime and *Tizraia*? Said and Rodriguez. Such a generic assemblage is unknown elsewhere above the Serpukhovian. An upper? Bashkirian specimen of *Paraheritschioides* Sando, collected above the main fauna, is the oldest known representative of that genus. Faunal comparisons suggest Novaya Zemlya or northern Timan as the most likely source areas for the Yelverton Inlet fauna.

87564 <SOURCE>Journal of Paleontology 86, 3: 513-520.</SOURCE>
87565 <ABSTRACT>Four new species of colonial corals, one previously described coral, and two other unidentified species of coral have been recovered from the Baird Formation in the Klamath Mountains of northwestern California. The newly erected species are *Heritschioides armstrongi* n. sp., *Pararachnastraea klamathensis* n. sp., *P. watkinsi* n. sp., and *P. kabyaiensis* n. sp. These corals are associated with the fusulinids *Millerella marblensis* Thompson, 1944, *Paramillerella* Thompson, 1951, and *Pseudostaffella* Thompson, 1942, emend Groves, 1984, suggesting an early Atokan (Bashkirian) age. Both the coral and foraminiferal faunas bear a resemblance to those of similar age in the Brooks Range, Alaska, which could suggest geographic proximity between the two terranes at that time. These corals also represent the earliest known occurrence of

- the Family Durhamididae.</ABSTRACT>

87577 <SOURCE>Bulletin of Geosciences 86, 1: 49-61.</SOURCE>
87578 <ABSTRACT>The Silurian to Devonian Gionyama Formation is assigned to the Kurosegawa Terrane in Southwest Japan. Abundant rugose corals in the Middle Member (late Llandovery to early Ludlow) of this formation represent 18 species belonging to 13 genera. These species are: Tryplasma sp. aff. T. ozakii, Tryplasma sp. A, Tryplasma sp. B, Cystiphyllum sp., Holmophyllum sp., Holmophyllum? sp., Labechiellata regularis, Rhizophyllum sp. A, Rhizophyllum sp. B, Neobrachyasma japonica, Pseudamplexus sp., Amsdenoides sp., Amplexoides sp. aff. A. chaoi, Strombodes sp., Nanshanophyllum hamadai, N. gokasense, Shensiphyllum sp., and Ptychophyllum sp. The rugose corals from the Gionyama Formation include cosmopolitan genera that commonly occur in China, Kazakhstan, Siberia, Gotland, eastern Australia, and North America. Endemic genera, such as Nanshanophyllum and Shensiphyllum, which only occur in South China and Qaidam, are also present. Their stratigraphic ranges are restricted to the late Llandovery. The occurrences of these endemic genera may indicate a strong paleobiogeographic relation between the South China Block and "Proto-Japan" during the Silurian.</ABSTRACT>

87589 <TITLE>Extinction of Guadalupian rugose corals: an example of biotic response to the Kamura event (southern Primorye, Russia).</TITLE>
87590 <SOURCE>In: Gasiewicz A. & Slowakiewicz M. (eds) Palaeozoic Climate Cycles: Their Evolutionary and Sedimentological Impact. Geological Society, London, Special Publication 376. First published online August 6, 2013, <http://dx.doi.org/10.1144/SP376.13></SOURCE>
87591 <ABSTRACT>Permian Rugosa of southern Primorye (Russian Far East) occur in a series of terranes of different tectonic origin. The taxonomical composition of Guadalupian (Wordian-Capitanian) rugose corals distributed in southern Primorye changed progressively in an ecological succession, starting with primitive persistent cosmopolitan taxa (assemblage I). This was replaced by assemblage II with a marked invasion of Peri-Gondwanian genera such as Timorphyllum and Verbeekiella, and, in the Late Capitanian, by typical Cathasian colonial waagenophyllids (assemblage III). Subsequent communities have nearly no transitional forms. The latter assemblage was abruptly replaced by small fasciculate and solitary primitive forms (assemblage IV). Species peculiarities of assemblages of the Parafusulina stricta Zone and the specific lithological features of coral-bearing deposits indicate a palaeogeographical differentiation of terrane positions. The terranes are of various origins: oceanic arcs, passive margin and

guyot. The extinction of massive colonial Rugosa in southern Primorye (western Palaeo-Pacific) is identified as a biotic event that is recognizable in Japan, and probably in Inner Mongolia. It also coincides with a general reduction in coral diversity at the end of the Capitanian in China. The present study of the taxonomical distribution of corals has enabled the level of massive waagenophyllid extinction to be defined precisely and to correlate it to a similar pattern in adjacent territories of the Palaeo-Pacific below the Lopingian boundary. The diversity decrease coincides with the last phase of the Kamura event, and the effects of the Emeishan volcanism is correlated with a second positive shift in $\delta^{13}C$ (South China). The assumed cooling impacted on the fauna in the western Palaeo-Pacific. The stepwise elimination of massive colonial waagenophyllids and large fusulinids documented in the southern Primorye at the end of the Capitanian is considered to be the first step in the Permian-Triassic extinction, about 8 Myr prior to the final Permian-Triassic (P-T) global event.

87616 <SOURCE>In: Aretz, M., Delculee, S., Denayer, J., & Poty, E. (Eds.): 11th Symposium on Fossil Cnidaria and Porifera, Liege, August 19-29, 2011, Abstracts; Kölner Forum für Geologie und Paläontologie 19: 94-95.</SOURCE>

87617 <ABSTRACT>Endophyllum are subfasciculate, cerioid or aphroid corals. Corallites large, with septal stereozone broken up by large irregular lonsdaleid dissepiments. Major septa long, attenuate, and commonly convolute in the tabularium. Endophyllum is a cosmopolitan genus in the Middle Devonian (Givetian) of Europe, Australia and Asia including South China. Specimens referred to so-called "Endophyllum" were reported from northern Xinjiang, NW China (Cai 1983, Liao & Cai 1987). However, they differ obviously from the Endophyllum of Europe and South China in the morphology of their epitheca, septa, dissepiments, tabulae and even in their minute skeletal structures. The major septa of "Endophyllum" from northern Xinjiang are not convolute in the tabularium. Its tabularium is rather simple and the minute skeletal structures of the septum are probably composed of composite rhabdacanth. We transfer the Xinjiang materials to a new genus, Parendophyllum. Parendophyllum Liao & Ma 2011 (type species:

Parendophyllum stereoplasma Liao & Ma 2011) Diagnosis: corallum is cerioid, corallites are large, with a thick septal stereozone and a large irregular lonsdaleoid dissepiments, Septa of two orders, major septa are long but not convolute in tabularium, Tabularium is rather simple and tabulae are convex or horizontal. The minute skeletal structures of septum are composed of composite rhabdacanth... [abridged]

87628 <TITLE>Mixed Tethyan and McCloud Belt Rugose Corals and Fusulinids in an Upper Triassic Conglomerate, Central Oregon.</TITLE>

87629 <SOURCE>Journal of Paleontology 87, 5: 909-921.</SOURCE>

87630 <ABSTRACT>Colonial rugose corals ranging in age from Carboniferous to Late Triassic and Early Permian (Cisuralian) fusulinids have been recovered from cobbles in a conglomerate in the Upper Triassic Brisbois Member of the Vester Formation in the Izee terrane in central Oregon. Early Permian (late Sakmarian or early Artinskian) fusulinids typical of those present in the Coyote Butte Limestone in the nearby Grindstone terrane (part of the allochthonous McCloud Belt) include Eoparafusulina, Pseudofusulinella, Chalaroschwagerina, and Schwagerina. The presence of these fusulinid genera and the Pennsylvanian coral Heritschioides?, which is mostly restricted to the McCloud Belt, suggest these particular cobbles were derived from limestone in that belt. The Early Permian fusulinids Changmeia bostwicki new species and Changmeia bigflatensis new species, and the Early Permian corals Yokoyamaella? oregonensis new species and Yokoyamaella? sp. 1, all of which have Tethyan affinities, occur rarely in other cobbles. The presence of definitive fossils from the two different realms in a conglomerate associated with beds containing Late Triassic ammonoids indicates that by Late Triassic time a fragment of a Tethyan terrane was close to or had been amalgamated with a terrane belonging to the McCloud Belt.</ABSTRACT>

87655 <SOURCE>Geologica Belgica 15, 4: 254-264.</SOURCE>
87656 <ABSTRACT>The genus *Angustiphyllum* is recorded for the first time in the Armorican Massif (Rade de Brest) and two new species are erected: *A. stylophorum* and *A. vidalae*. The well preserved material shows the indisputable presence of costae on the exterior side of the corallum, which, besides the wedge-like morphology of the corallum, constitutes the main diagnostic feature of the genus. *Angustiphyllum* seems to be a good index for the upper Eifelian of the Ibero-Armorican Domain.

87667 <TITLE>Gregarious growth versus colonial habit in the rugose coral family Geyerophyllidae Minato, 1955.</TITLE>
87668 <SOURCE>Geologica Belgica 15, 4: 355-360.</SOURCE>
87669 <ABSTRACT>The family Geyerophyllidae Minato, 1955 includes corals having clinotabulae, lonsdaleoid dissepiments and a variable complex axial structure formed as an extension of the cardinal septum. Included in the family are four genera originally considered to have a colonial (fasciculate) growth habit - *Carniaphyllum* Heritsch, *Carinthiaphyllum* Heritsch, *Lonsdaleoides* Heritsch, and *Darwasophyllum* Pyzhyanov. More recent studies and a review of the type specimens of *Carniaphyllum*, *Carinthiaphyllum* and *Lonsdaleoides* have shown them to be solitary corals with a gregarious growth habit. In its original description and in all subsequent works, *Darwasophyllum* has consistently been referred to as a fasciculate coral, but the presence of offsets has not been illustrated in the genus and a colonial growth habit has not been clearly demonstrated. Early Serpukhovian specimens of *Darwasophyllum* from the Etherington Formation (Mississippian) in Canada were initially regarded as fasciculate colonies with long, sub-parallel, closely spaced corallites. When they were studied in detail by means of serial sections, however, these corals were found to be solitary individuals grouped into gregaria, without shared structures or offsets. Thus, true colonies are unknown in the Geyerophyllidae and all genera described as colonial in that family consist of gregarious, solitary corals.

- 87681 <TITLE>An upper Visean (Asbian-Brigantian) and Serpukhovian coral succession at Djebel Ouarkziz (Northern Tindouf Basin, Southern Morocco).</TITLE>
- 87682 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 119, 1: 3-17.</SOURCE>
- 87683 <ABSTRACT>The Djebel Ouarkziz Formation, located in the northern part of the Tindouf Basin, in western Algeria and southern Morocco, is composed mainly of shales with interbedded limestones, dolostones and sandstones. The limestone beds are relatively thin, but are laterally persistent, and can be followed along strike for tens of kilometres. We have identified 19 limestone beds in three main sections; one logged along the road from Assa to Zag, a second in the Tinguiz-Remz Valley, 15 km to the east, and a third section 10 km west of the Assa-Zag road section. Rugose coral assemblages are recorded in most limestone beds, but the stratigraphically higher beds become more diverse. However, many rugose genera and species are persistent throughout much of the succession. The oldest coral assemblages are Asbian in age and the youngest coral assemblages indicate a Serpukhovian age, as confirmed by foraminiferal biostratigraphy. The first appearance of rugose corals shows a different pattern than that in northern Moroccan basins; some common genera that first appear in the Asbian and lower Brigantian in northern Morocco and Europe, appear much later, in the upper Brigantian or Serpukhovian in the Djebel Ouarkziz. The genus *Kizilia*, which is rare in the Upper Visean in northern Moroccan basins, is, however, abundant in the Tindouf Basin. Interestingly, the occurrence of the genus *Lonsdaleia* in the Serpukhovian from Djebel Ouarkziz poses a palaeogeographic problem because of its absence in northern Moroccan basins (except as transported elements in Serpukhovian conglomerates). Similarly, *Actinocyathus* in the Serpukhovian in the Tindouf Basin is not present north of the Anti-Atlas Mountains. A possible coral migration route to the Tindouf Basin may be from the northeast via the Bechar Basin in Algeria, similar to that already inferred for foraminifers and calcareous algae.</ABSTRACT>

- 87695 <SOURCE>Spanish Journal of Palaeontology 28, 2: 255-284.</SOURCE>
- 87696 <ABSTRACT>A rich rugose coral assemblage has been recorded from a biostrome at the top of the Djebel Ouarkziz Fm in the Tindouf Basin, S. Morocco. It is composed of 10 genera and 14 species, of which 5 are new. It represents essentially a Mississippian-type coral fauna but with some evolved species. However, its age, as determined by foraminifers and conodonts, is lower Bashkirian (Lower Pennsylvanian). The presence of Mississippian-like corals in the Bashkirian indicates that the epicontinental basins in northern Gondwana (Saharan basins) were a refuge for coral faunas during the late Serpukhovian extinction event. The persistence of the Mississippian assemblages in the Bashkirian from northern Gondwana was probably due to a combination of warm waters and tectonic stability. The coral assemblage from the Tindouf biostrome is similar to those corals recorded from Ellesmere Island, Arctic Canada and Novaya Zemlya, Arctic Russia where similar tropical warm water conditions have been identified during the Bashkirian in the northern hemisphere.</ABSTRACT>

87708 <SOURCE>Gondwana Research 13, 1: 367-379.</SOURCE>
87709 <ABSTRACT>Analysis of Mississippian coral assemblages from the Khenifra region of Central Morocco together with data from foraminiferal / algal microfossils has established new age dating of 5 localities within the Azrou-Khenifra Basin: Souk El Had and Sidi Lamine, where corals occur mainly in biostromes protected by oolitic shoals, Tabainout, where corals have been recorded in different environments related to microbial mounds, Alhajra Almatkouba, where corals occur in biostromal reworked beds and Tiouinine, where corals occur in a well-structured, fringing reef. This study demonstrates the presence of richer more diverse coral assemblages than previously recorded, in a variety of environmental settings. These coral assemblages strengthen correlations with the Adarouch area in the NE part of the Azrou-Khenifra Basin. It is emphasized that in the upper Visean there are close similarities with rugose coral assemblages in other parts of the western Palaeotethys including North Africa, SW Spain and NW Europe, and that all belong to the same biogeographic province.</ABSTRACT>

87720 <TITLE>Mississippian coral assemblages from Tabainout mud-mound complex, Khenifra area, Central Morocco.</TITLE>
87721 <SOURCE>Geologica Belgica 15, 4: 308-316.</SOURCE>
87722 <ABSTRACT>Analysis of Mississippian coral assemblages from the Khenifra region of Central Morocco has demonstrated the presence of a rich and diverse coral fauna. Rugose coral assemblages from the Tabainout mud-mound complex comprise abundant colonial and solitary taxa, particularly in the basal bedded limestones, as well as the upper bedded flank and coquina capping beds. The massive core facies with stromatactoid cavities in contrast has rare solitary corals. The overlying shales, marls and limestone bands which buried the mud-mound are dominated by small non-dissepimented solitary rugosans. The age of the Tabainout mound based on foraminifers is established as upper Visean (late Asbian-late Brigantian). The coral assemblage strengthens correlations with the Adarouch area in the northern part of the Azrou-Khenifra Basin where similar mud mounds occur. These assemblages also show similarity with coeval coral faunas from the Jerada mud-mounds (buildups) of NE Morocco and together represent part of the same palaeobiogeographic province (Western European Coral Province).</ABSTRACT>

87733 <TITLE>Rugosans immured in Silurian Paleofavosites, Brassfield Formation (Llandoverly) of Ohio.</TITLE>
87734 <SOURCE>Geologica Belgica 15, 4: 220-225.</SOURCE>
87735 <ABSTRACT>The occurrence of a solitary rugose coral, Streptelasma sp., anchored within colonial skeleton of the tabulate coral Paleofavosites prolificus is here reported. Numerous specimens of Streptelasma were found within three coralla of this tabulate species among 55 collected from the uppermost 30 cm of the Lower Silurian (Llandoverly) Brassfield Formation at Fairborn, Ohio. These rugosans are largely immured in the favositid coralla, and, as bioclastrations, reveal important information on the paleobiology of both species. However, the immuring of some Streptelasma within Paleofavosites coralla was not complete during the life of the rugosan, as calice openings of these are present at the corallum surface. Complete immuration (or total overgrowth) indicates that the rugosan no longer competed successfully for space, whether entombment occurred after the death of the rugosan or was the cause of its death is unknown. Streptelasma, in assuming an epibiotic lifestyle probably benefited from the secure attachment to the larger, stable colonial form of Paleofavosites prolificus and were able to exist within this particular Brassfield facies interpreted to have been a vigorous, current-swept environment. These high energy environments would have been inimical to the small, light-weight rugosans living as isolated corallites. The successful settling and growth of the rugosans on the tabulate colonies reflects their higher status in an aggression hierarchy. This interspecies interaction indicates an early Paleozoic development of an aggression hierarchy of corals belonging to the Rugosa and Tabulata (Phylum Cnidaria).</ABSTRACT>

87746 <TITLE>New unusual skeletal structure in an Upper Carboniferous rugose coral, Klamath Mountains, Northern California.</TITLE>
87747 <SOURCE>Journal of Paleontology 86, 1: 120-125.</SOURCE>
87748 <ABSTRACT>Unique among the Rugosa are specialized cyst-like structures in corals from an upper Carboniferous limestone within the Baird Formation in the Klamath Mountains, northern California. These structures, here referred to as septal cysts, occur mostly along the distal margins of the dark line extending along the axes of the major septa as seen in transverse section. However, they also commonly extend beyond the distal extent of those lines and may interrupt the fibrous coating in the more proximal parts of some septa. Their function is uncertain. Also present are small dissepiments which form a ring around the distal margins of the minor septa. These structures, however, do not appear to be related to the development of those septa. Some other taxa, including corals from the Bashkirian of Spain and the Kasimovian of Kansas, possess some specialized structures similar to those in the California specimens suggesting at least a remote relationship.</ABSTRACT>

87759 <TITLE>Comments on subspecies of Calceola sandalina.</TITLE>
87760 <SOURCE>In: Aretz, M., Delculee, S., Denayer, J., & Poty, E. (Eds.): 11th Symposium on Fossil Cnidaria and Porifera, Liege, August 19-29, 2011, Abstracts. Kölner Forum für Geologie und Paläontologie 19: 190.</SOURCE>
87761 <ABSTRACT>The neotype of the type species of Calceola, C. sandalina Linne, 1771, was selected and illustrated by Richter (1928)... But what are the diagnostic features of Calceola sandalina sandalina? Goldfuss (1840) erected C. s. var. dilatata and C. s. exaltata, both of which were regarded by Richter (1928) as junior synonyms of the type subspecies. Other German subspecies of C. sandalina... Focussing on German subspecies, it is well known that these were largely based on the apical angle of the corallite, the curvature of the counter face, and the related length/width ratio of the corallite. No attention has been paid to other morphological features such as shape of the operculum, numbers of septa or patterns of septal insertion... [abridged]</ABSTRACT>

87772 <TITLE>Soft taxonomy - case of Devonian phillipsastreid rugose corals.</TITLE>
87773 <SOURCE>In: Aretz, M., Delculee, S., Denayer, J., & Poty, E. (Eds.): 11th Symposium on Fossil Cnidaria and Porifera, Liege, August 19-29, 2011, Abstracts. Kölner Forum für Geologie und Paläontologie 19: 191-193.</SOURCE>
87774 <ABSTRACT>Analysis of nine genera or species groups of Devonian massive phillipsastreid rugose corals indicates difficulties in obtaining sharply distinguished taxa at genus level. This may indicate either close genetic affinity within the group studied, or/and its high phenetic plasticity. The other factor responsible may be small size of variability space analyzed... In attempt to overcome the limitations of such a "statistical" analysis, the next step was comparison of genera, pair by pair and character by character. The following 11 characters were established as of primary importance, i.e. permitting in some cases sharp distinction between genera: MU - wall type, SC - septal continuity, IN1 - internal wall, IN2 - length of septal expansion, PP - horseshoe dissepiments, DIC - corallite size, #S1 - septal number, TM - tabularium diameter, L1 - length of major septa, D1 - septal thickness, TT - spacing of tabulae / tabellae. The other characters were found less significant... [data analysis indicates that] Medusaephyllum Roemer 1855... should be included wholly or in part into Phillipsastrea d'Orbigny 1849... Sudetiphyllia Fedorowski 1991 [is] well defined and distinct genus [abridged]</ABSTRACT>

87811 <TITLE>Growth characteristics in co-occurring Upper Ordovician species
of the tabulate Catenipora from southern Manitoba, Canada.</TITLE>
87812 <SOURCE>Lethaia 46, 1: 98-113.</SOURCE>
87813 <ABSTRACT>Four species of the tabulate coral Catenipora are present in
the Selkirk Member of the Red River Formation at Garson, Manitoba. They
provide an opportunity to compare the growth characteristics of
multiple, co-occurring species that produced cateniform coralla.
Corallite increase, cyclomorphism and other growth features show high
variability within and/or among the species. A total of five types of
lateral increase and two types of axial increase are recognized.
Lateral increase accounts for over 80% of all occurrences of corallite
increase in each species, with the four species differing significantly
in the relative frequency of the various types of lateral increase. The
type of axial increase, megacorallites and agglutinated patches of
corallites that developed from normal, undamaged corallites in C.
foerstei are species specific. In all species, cyclic fluctuations in
the tabularial area of corallites are considered to be annual, and the
variable growth rates within colonies and species are attributed to
differences in astogenetic stages or environmental conditions. Average

annual vertical growth was positively correlated with average tabularial area in *C. foerstei*, *C. cf. robusta* and *C. rubra*. *Catenipora cf. agglomeratiformis*, however, which had the lowest average tabularial area and greatest sensitivity to sediment influx, had a high average growth rate comparable to that of *C. rubra*, which had the largest average tabularial area. The formation of ranks or lacunae by certain types of lateral increase seems to have been the most effective strategy for maintaining and/or expanding the colony growth surface in all four species, and was most common in *C. cf. agglomeratiformis*. A reptant growth pattern, characterized by creeping ranks, permitted effective recovery of damaged parts as well as quick formation of new ranks or lacunae. The growth surface of these species was situated near the sediment-water interface. </ABSTRACT>

87824 <TITLE>Unusual tabulate-crinoid biocoenosis from the Lower Devonian of Morocco</TITLE>

87825 <SOURCE>Lethaia, doi: 10.1111/let.12048</SOURCE>

87826 <ABSTRACT>The Early Devonian (Pragian: *sulcatus* to *pireneae* conodont zones) crinoid-coral biocoenosis from Hamar Laghdad, Morocco contains fragments of crinoid stalks of various taxa encrusted by spherical and ellipsoidal coralla of the tabulate coral *Hamarilopora minima*. These corals were encrusting host crinoids *syn vivo*, and this is evidenced by pluricolumnals exceeding 30 elements overgrown from all sides. Most known to date crinoid-epibiont associations display various types of reaction to the epibiont, such as swellings and deformations. In the case discussed here, no clear interaction is visible; therefore, this association can be classified as *paroecia*. It can be inferred, however, that due to a change in mechanical properties of the crinoid stalk (losing flexibility), the epizoan influence on the host was negative, while the coral was profiting from the elevated position over the seafloor and nutrient-bearing water currents. It can be supposed that this interaction was close to parasitism. No strict species-specific relationship between the epizoan and the host was observed. </ABSTRACT>

87837 <TITLE>Primary biogenic skeletal structures in *Multithecopora* (Tabulata, Pennsylvanian)</TITLE>

87838 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 386: 286-299</SOURCE>

87839 <ABSTRACT>Corals are significant components of fossil marine communities and important for paleoenvironmental reconstructions throughout the Phanerozoic. Despite their abundance and diversity in Paleozoic rocks, the presence, and criteria for the recognition of primary, biogenic skeletal structures is highly controversial. The aim of this study is a multilevel analysis of the diverse morphological elements that form well-preserved specimens of the Carboniferous

Multithecopora tabulate coral skeleton. Results indicate that samples are minimally altered by diagenesis, but most importantly that skeletal structures are biogenic in nature, and similar to those of modern and fossil carbonate-producing organisms. Nano- and microcrystals form a complex framework of different domains of crystal morphologies that comprise the bulk of the skeleton in Multithecopora. These domains are thought to be the possible phenotypic response of the genotype of these corals, and had a structural importance during the life of the organism. Overall, this study sheds light for a better understanding on the controversy that exists about the biogenic or abiogenic origin of the Paleozoic coral microstructures.</ABSTRACT>

87851 <SOURCE>Bulletin of Geosciences 85, 2: 317-352</SOURCE>

87852 <ABSTRACT>Two sections were sampled and measured at Mdaour-El-Kbir (Dra Valley, western Anti-Atlas) and at eastern Ouidane Chebbi (Tafilalt, eastern Anti-Atlas). In situ elements of two partially limonitized and one carbonatic fauna were found in both sections. We report this fauna from the upper Merza-Akhsai Formation and the lower Mdaour-el-Kbir Formation at Mdaour-el-Kbir for the first time. Based on these faunas, we recorded a correlation of the early Emsian (Zlichovian) strata in the Tafilalt and the Dra Valley regions, which are about 350 km apart. Additionally, new ammonoid finds (Teicherticeras cf. senior, Lenzites gesinae, Weyeroceras angustus) are figured and described including the stratigraphic context. The diagnoses of Lenzites gesinae and Weyeroceras angustus are emended. Tabulate corals (Michelinia mdaourensis sp. nov., Petridictyum sp.) found in both the Tafilalt and Dra Valley are figured and described for the first time.</ABSTRACT>

87863 <TITLE>Heliolitine tabulate corals from Late Ordovician and possibly early Silurian allochthonous limestones in the Broken River Province, Queensland, Australia</TITLE>

87864 <SOURCE>Alcheringa 36, 1: 1-30</SOURCE>

87865 <ABSTRACT>Coral faunas of Late Ordovician (Ashgill) and possibly early Silurian age are present in allochthonous limestone blocks incorporated in debris flow deposits in the Broken River Province of north Queensland. The limestones occur in the Carriers well Formation and Crooked Creek Conglomerate, which now lie within structurally deformed fault slices, and are evidence of the existence of a former carbonate platform of this age situated to the west. The fauna from the Carriers well Formation includes 15 taxa belonging to the heliolitine coral families Heliolitidae, Pseudoplasmoporidae, Plasmoporidae, Plasmoporellidae and Sibiriolitidae. New taxa present are Wairunalites

greeni gen. et sp. nov. and Plasmoporella marginata sp. nov. The fauna includes other species belonging to Heliolites, Plasmoporella and Sibiriolites in common with Late Ordovician faunas of New South Wales, central Asia and northern China. A limestone block in the Crooked Creek Conglomerate contains a few non-diagnostic heliolitine corals, together with rugosan, favositine and halysitine corals similar to those in the blocks of the Carriers well Formation, but it also contains several alveolitine tabulates suggesting a possible early Silurian age.

87889 <TITLE>Pseudopercula in Thamnopora orthostachys, Plabutsch Formation (Eifelian), Graz Palaeozoic</TITLE>

87890 <SOURCE>In: Aretz, M., Delculee, S., Denayer, J., & Poty, E. (Eds.): 11th Symposium on Fossil Cnidaria and Porifera, Liege, August 19-29, 2011, Abstracts. Köln Forum für Geologie und Paläontologie 19: 55-56</SOURCE>

87891 <ABSTRACT>The Graz Palaeozoic, part of the Upper Austroalpine Variscan sequence, represents a diversity hot spot of corals belonging to the "Austroalpine Coral Fauna" (Hubmann 2002)... Among them, very common are branches of thamnoporids which were named Pachypora orthostachys by Penecke (1894: 607). Actually this tabulate belongs to Thamnopora, but we do not comply with Kropfitsch & Schoupe (1953) that the species "orthostachys" is a younger synonym of Th. reticulata (Blainville). However, detailed studies of surfaces of Thamnopora orthostachys from two separate outcrops (Marmorbruch and Fuchsloch) yielded in several specimens concentrically wrinkled structures at the bottom of some corallites... [named] ..."pseudopercula". Pseudopercula ... are calcareous membranes closing the apertures of certain corallites. Pseudopercula occur preferentially at the basal parts of branches... The formation of pseudopercula is therefore obviously a reaction of the thamnoporid colonies to protect their tissue in stressed zones. The sealing of portions of the colonies represents a strategy to preserve as much of the soft body as possible under stress conditions. Logically, polyps trapped under a close cover could not

- scavenge for food, but were able to communicate over the pore system.

87915 <TITLE>Growth characteristics of Protoheliolites norvegicus (Tabulata; Upper Ordovician; Estonia)</TITLE>
87916 <SOURCE>Palaeontology 56, 4: 867-891</SOURCE>
87917 <ABSTRACT>Protoheliolites is an early heliolitine coral characterized by closely spaced corallites separated in places by sparse coenenchyme. Growth characteristics in the type species, P. norvegicus, are revealed by detailed analysis based on serial peels and thin sections of coralla from the uppermost Katian of north-western Estonia. Colonies of this species had a strong ability to recover from damage and partial mortality, resulting in various forms of rejuvenation, regeneration, fusion and reorganization of corallites; in some cases, this involved relatively large areas of undifferentiated soft parts. The shells of commensal cornulitids became enclosed in host coralla during colony growth. Coralla of P. norvegicus exhibit distinctive growth cycles due to responses to seasonal changes. The production of new corallites by coenenchymal increase usually occurred in low-density bands, in which corallites generally display round to subrounded transverse outlines. In high-density bands, the corallites became crenulated, their wall thickness increased, septal development was more pronounced, and the amount of coenenchyme increased. In addition to these cyclomorphic changes, there were significant astogenetic changes during growth. Compared with the early stage of colony development, distinctive characteristics in the late astogenetic stage include a decrease in the growth rate of the colony, better coordination among corallites, maximum development of corallite crenulations and septa in high-density bands, more numerous coenenchymal tubules and a greater proportion of corallum area occupied by coenenchyme. In general, the role of polyps in determining morphological characteristics of individual corallites, such as tabularium area, corallite crenulations and wall thickness, was subordinate to the astogeny of the colony. Growth characteristics including colony-wide coordination of polyp behaviour and subjugation of individuals to restore the colony following damage suggest a strong

- astogenetic control and high level of colony integration. Protoheliolites probably arose from a heliolitine genus rather than from a nonheliolitine group as some authors have proposed. </ABSTRACT>

- 87928 <TITLE>The oldest heliolitids from the early Katian of the East Baltic region</TITLE>
- 87929 <SOURCE>Geologiska Foreningens Forhandlingar (GFF) 134, 3: 225-234</SOURCE>
- 87930 <ABSTRACT>The earliest heliolitids appeared more or less simultaneously in the Late Ordovician shallow seas of different palaeocontinents. In this paper the early Katian heliolitids, represented by the genus Protaraea, are described from the East Baltic region (North Estonia and north-west Russia) and discussed in detail for the first time. A new species Protaraea procella n. sp. Motus is established and a neotype for Protaraea diffluens (Eichwald) is designated. The new species shows a wide intraspecific variability including variably oriented septal trabeculae, which results in corallites commonly being poorly defined or not apparent in transverse sections of coralla. P. procella has much larger coralla than P. diffluens, with predominantly laminar growth forms, whereas the latter species is usually encrusting, suggesting that the two species were adapted to different palaeoenvironmental conditions. The new data indicate that these heliolitids, together with other tabulate corals, were already geographically dispersed in the early Katian and thereby contribute to a better understanding of coral diversification patterns in Baltica.</ABSTRACT>

- 87942 <SOURCE>Bulletin of the National Science Museum, Series C, Geology & Paleontology 34: 43-50; Tokyo</SOURCE>
- 87943 <ABSTRACT>A new outcrop of the Hitoegane Formation in the Shinhirayuonsen area, Takayama-shi, Gifu Prefecture is discovered, resulting in a stratigraphic redefinition of the formation as the Late Silurian (mainly Ludlow) shallow marine succession. Fossiliferous limestone (biolithite and bioclastic wackestone), tuffaceous sandstone and shale are principal constituents of the formation, whose thickness ranges 40-50 m, but its original thickness was in excess of those amounts. The auloporid tabulate corals in the present new locality are described. They are Aulopora? sp. indet., Syringoporella yamakoshii Niko, 2001 and Aulostegites? sp. indet. Among them, S. yamakoshii is a common species with the type locality of the formation.</ABSTRACT>

88033 <SOURCE>Bulletin of the National Museum of Nature and Science, Series C, Geology & Paleontology 34: 39-42; Tokyo</SOURCE>
88034 <ABSTRACT>A new auloporid tabulate coral species, Aulostegites nodai, is described from the upper Wenlock (Lower Silurian) G2 Member of the Gionyama Formation in the Kuraoka area, Miyazaki Prefecture. The Early Silurian species differs from a comparable species, A. longlinensis Chow in Xian et al., 1980 from the Lower to Middle Devonian of South China, in its smaller corallite diameters and shorter spine-like projections. Aulostegites sp. indet. (Senzai and Niko, 2003) from the Fukata Formation, Yokokurayama Group, Kochi Prefecture is conspecific with A. nodai.</ABSTRACT>

88123 <TITLE>Taxonomical problems of the Heliolitida</TITLE>
88124 <SOURCE>Geologica Belgica 15, 4: 215-219</SOURCE>
88125 <ABSTRACT>Systematic position of group is accepted by the beginning scientist after the teacher or after the leader in the field of studying of this group of corals. But the lowest categories (species and genera) are established by him, first of all, on a regional material. Long-term study of heliolitids of Central Tajikistan and their comparison with heliolitids from other regions shows faunistical peculiarity of each region. Ambiguity of treatment of the same morphological features as a result takes place. The situation becomes complicated by parallelism of development between some taxa of the Heliolitida and wide variability of features of many species. Standardization of arrangement of coenenchyme because of parallelism of development results in occurrence of forms with a similar structure, but with a different genetic basis. So we can tell now that the main problem in definition of taxa of the Heliolitida is the heterogeneous genus Heliolites.</ABSTRACT>

88137 <SOURCE>Ferrantia 58: 72-80; Luxembourg</SOURCE>
88138 <ABSTRACT>A new species of Kerforneidictyum, K. oeslingensis n. sp., is described. It is mainly characterized by the following features: apical angle reaching up to 160°; deep calices with numerous small spines roughly of the same size, setted in two rows or scattered on septal ridges which are wider than the interseptal furrows, no obvious cardinal ridge, tabulae scarce or missing. The species has been collected in the lowermost Emsian of the Givonne-Eislek Anticlinorium in Luxembourg. It is 1) the first record of the genus in the Devonian of Luxembourg and 2) in the autochthonous part (S.E. Laurussia) of the Ardenno-Rhenish Mountains and 3) very likely the first - or one of the two first - representative of the genus taking into account Gondwana and Laurussia.</ABSTRACT>

88149 <TITLE>Self-organization and emergent individuality of favositid corals adapted to live on soft substrates.</TITLE>
88150 <SOURCE>Lethaia 45, 1: 2-13.</SOURCE>
88151 <ABSTRACT>Secondary soft-bottom dwellers share the problem that their ancestors, attached to hard substrates, had lost their mobility. On soft substrates, only a limited number of alternative tricks are available to maintain sessile organisms in life position or to right them following disturbance. Consequently, convergent adaptations have emerged in unrelated members of this ecological guild. Those of favositid corals are of particular interest because, on account of their small polyps, they were always colonial. A comparative analysis of forms adopted by favositids on soft substrates shows that key elements of their adaptive paradigms could have been achieved by self-organization. This arose without centralized control by means of inherited reaction norms of individual polyps to local environmental conditions. The unique spiral growth habit of Favosites turbinatus Billings and its emergent individuality at the colony-level of organization are explained in these terms. "suicidal" lids entombed altruistic marginal polyps, forming a secondary epitheca as the growing colony settled into the sediment. These lids also record the size and spacing of soft tentacles in this species.</ABSTRACT>

88175 <TITLE>Tabulate corals from the Givetian and Frasnian of the southern region of the Holy Cross Mountains (Poland).</TITLE>
88176 <SOURCE>Special Papers in Palaeontology 87: 3-100.</SOURCE>
88177 <ABSTRACT>Givetian and Frasnian tabulate corals from the southern region of the Holy Cross Mountains, Poland, are described. Both Givetian and Frasnian tabulate faunas from the study region are dominated by alveolitids and comprise 52 species (Favositida: 40 species, Syringoporida: 6 species, Auloporida: 6 species). A new genus belonging to Syringoporida is proposed - Sapounofouskilites gen. nov. - and five new species are erected (Favositida: Striatopora sciuricauda sp. nov., Alveolites? obtortiformis sp. nov., Crassialveolites oliveri sp. nov., Roseoporella heuvelmansi sp. nov.; and Auloporida: Aulopora slosarskii sp. nov.). Study of the intracolony variation in tabulates shows that minimal and maximal corallite lumen diameters and pore diameters are the best taxonomical discriminators for Alveolitidae and Coenitidae, while the double wall thickness and tabulae spacing are less useful characters. Moreover, alveolitids and coenitids show overall greater intracolony variation than, for example, heliolitids. The tabulate endobiont Chaetosalpinx? plusquelleci isp. nov. is newly described. Study of tabulate endobionts - that is, Chaetosalpinx? plusquelleci, Helicosalpinx cf. asturiana Oekentorp and H. isp. - show that these were parasites of tabulate corals. Givetian and Frasnian tabulate faunas from the Kielce (southern) Region of the Holy Cross Mountains are dominated by Alveolitidae.</ABSTRACT>

88188 <TITLE>The oldest species of ?Yavorskia (Tabulata) from the Upper Famennian of the Holy Cross Mountains (Poland).</TITLE>
88189 <SOURCE>Acta Geologica Polonica 62, 2: 197-204.</SOURCE>
88190 <ABSTRACT>A single perfectly preserved colony of a tabulate coral assigned tentatively to the genus Yavorskia Fomitchev, 1931, collected from Upper Famennian beds (Palmatolepis expansa conodont Zone) in a trench located north of the Kowala Quarry (Holy Cross Mts., central Poland) is here described as a new species, ?Y. paszkowskii sp. nov. It differs from other representatives of the genus in the lack of dissepimental structures and in smaller corallite diameters, and may therefore represent the ancestral taxon of this typically early Carboniferous genus. Yavorskia tabulates were apparently migrating eastwards along the southern margin of Laurussia and farther east and north towards Siberia, as they appear in the Famennian in Europe and in the early Carboniferous in the Altai. Such a conclusion is consistent with previous observations on Early-Middle Devonian Pleurodictyform tabulate distribution.</ABSTRACT>

88201 <TITLE>Blastogeny in tabulate corals: case studies using X-ray microtomography.</TITLE>
88202 <SOURCE>Lethaia 46, 2: 223-231.</SOURCE>
88203 <ABSTRACT>X-ray microtomography (XMT) is a non-invasive and non-destructive method that has often been used to study fossils. It allows serial sections to be made as little as few micrometers apart, such a resolution is unachievable for classical serial sectioning, moreover, in contrast to the latter, the specimen is not destroyed. Microtomography can, however, be applied only in cases where differences in X-ray absorption between the skeleton and its infilling are great. We show that this method may be also applied to tabulate corals. Case studies of blastogeny are based on Silurian (Aulopora, Favosites) and Devonian (Thamnopora) specimens from Poland. We show that the sequence of events in the blastogeny of Aulopora sp. is different from that of "Aulopora serpens minor" from the Devonian of the Holy Cross Mountains and similar to auloporids from the Devonian of England. Blastogeny in Favosites is very similar to that known from the related genera Squameofavosites and Thamnopora. This suggests that members of the genus Aulopora may be more diversified within the genus (as presently understood) than genera within the Favositidae.</ABSTRACT>

88214 <TITLE>A new Silurian Avicenia (Tabulata): taxonomy, growth pattern, and colony integration.</TITLE>
88215 <SOURCE>Geodiversitas 33, 4: 541-551; Paris.</SOURCE>
88216 <ABSTRACT>A new heliolitid tabulate coral Avicenia kocyani n. sp. is described from Silurian erratic boulders from Pomerania (Poland). The new species has higher intracolony variation than other heliolitids. The growth pattern in corallites of the new species is not correlated with the growth pattern in coenenchymal tubes. This phenomenon is probably caused by different gene expressions in corallites and common tissue. Coenenchymal corals with a common skeleton, developed as polygonal tubes may have two levels of colonial integration: lower, with uncoordinated growth of corallites and common tissue (as for example in Avicenia kocyani n. sp.) and higher, with a unified growth pattern throughout the colony (as for example in Heliolites diligensis Bondarenko, 1966). Heliolitids are known to show strong provincialism during the Silurian. The discovery of Avicenia Leleshus, 1974 in Europe (previously known only from Central Asia) shows that at least some of them had a wider distribution than previously thought.</ABSTRACT>

88227 <TITLE>Unusual growth pattern in the Frasnian alveolitids (Tabulata) from the Holy Cross Mountains (Poland).</TITLE>
88228 <SOURCE>Palaeontology 55, 3: 697-706.</SOURCE>
88229 <ABSTRACT>Growth periodicity is a phenomenon occurring in fossil and modern corals. The most apparent feature is growth banding, and environmental changes are broadly accepted as controls on this phenomenon. If environment controls the growth, then all corallites within a colony should repeat the same growth pattern, as individuals are clones and must have shared the same environment. A study on several species of Alveolitidae (Anthozoa, Tabulata) from the Late Devonian (Early Frasnian) of the Holy Cross Mountains (Poland) shows that the growth pattern varies between neighbouring individuals within the same corallum. This contradicts observations of closely related Favositida as demonstrated on Pachyfavosites sp. from the Givetian of Avesnois, France, where neighbouring individuals repeat the same pattern. Therefore, environmental control on growth rhythm in Alveolitidae can be excluded, the causes of differences between individuals remain unknown.</ABSTRACT>

88253 <TITLE>Catalogue of type collections of Early Cretaceous corals (Scleractinia, Anthozoa) at the National Museum of Natural History, Sofia.</TITLE>
88254 <SOURCE>Spisanie na Balgarskoto Geologicesko Druzestvo 72, 1-3: 129-140.</SOURCE>
88255 <ABSTRACT>The catalogue provides information about the availability of type material of Early Cretaceous coral taxa in the invertebrate fossil collections of National Museum of Natural History, Sofia, Bulgaria. The major part of the fossil coral type material was published by Zlatarski (1966; 1967a, b; 1968a, b; 1970; 1972). At present most of Zlatarski ´s type specimens and thin sections are housed in the museum. They belong to 24 coral species from the Barremian-Lower Aptian of several localities in central North Bulgaria (Fore-Balkan). Second well represented part of the coral type collection contains all the type specimens and all thin sections of 6 new species of Valanginian corals

collected in Lyubasha Mountain, Pernik district (Srednogorie, SW Bulgaria) and published by Roniewicz (2008). Some new species introduced by Zlatarski and Roniewicz are also type species of new genera. A syntype, described by Toula (1889) is also included in the catalogue.</ABSTRACT>

88266 <TITLE>Rise and fall of Pliocene free-living corals in the Caribbean.
</TITLE>
88267 <SOURCE>Geology 39: 375-378.</SOURCE>
88268 <ABSTRACT>Climate change is currently having an impact on shallow-water corals, and global circulation models predict that levels of pCO₂ and temperature will rise within the next century above anything recorded for at least the past 650 k.y. The Pliocene Epoch is a recent, albeit imperfect, geologic analog for such conditions in the Caribbean. Diverse communities of free-living solitary and flabellomeandroid (FSFM) corals inhabited shallow nearshore to deeper oligophotic habitats of the Pliocene. FSFM corals were well suited to the low-angle depositional profiles, increased productivity, increased sedimentation, and warmer temperatures of the Pliocene. Origination rates of FSFM coral species between 8 and 4 Ma are roughly double other zooxanthellate corals. FSFM corals underwent abrupt extinction between 2 and 1 Ma, as environmental conditions changed and suitable habitat was eliminated. The evolutionary bottleneck of Pliocene-Pleistocene extinctions and relic steep-margined Pleistocene topography may leave modern faunas vulnerable as we return to Pliocene-like conditions.

88279 <TITLE>Prolific development of pachythecaliines in Late Barremian, Bulgaria: coral taxonomy and sedimentary environment.</TITLE>
88280 <SOURCE>Annales Societatis Geologorum Poloniae 82: 291-330.</SOURCE>
88281 <ABSTRACT>Diversified and abundant corals of the suborder Pachythecaliina (order Hexanthinaria) are described from Upper Barremian, biostromal reefs of the Emen Formation, Lovech Urgonian Group, north central Bulgaria. The corals are mostly of the phaceloid growth form and represent 14 species (six new), 12 genera (three new), belonging to five families. Pachythecaliines occur along, with the small, monopleurid cylindrical rudist *Mathesia darderi*. The rudists frequently are densely clustered, occur between coral branches or are in contact with them. Other corals, with the exception of the phaceloid *Calamophylliopsis* and other rudists, are rare. Non-laminated microbialite crusts provided additional, structural support for bioconstruction development. Microbialites (automicroites) can be interpreted as a product of microbial activity, or alternatively, as a result of carbonate precipitation, brought about by non-living organic

substrates (organomineralization s.s.). In addition to microbialites, metazoans are encrusted by heterotrophic skeletal microorganisms, while photophilic and oligotrophic microencrusters, usually common in other coral-bearing limestones of the Emen Formation, are very rare. The section at the Rusalya Quarry (NW of Veliko Tarnovo), about 42 m thick, provides the sedimentary and environmental context for the reefal biostromes. The vertical biotic and sedimentary succession displays a general shallowing trend: from the outer carbonate platform with bioclastic limestones containing small boundstone patches (corals, but not pachythecaliines, *Lithocodium aggregatum*), to the inner platform with rudist biostromes. The pachythecaliine-rich biostromes, 2.5 m thick, were developed in a low-energy environment, referred to the distal part of the rudist-dominated area of the platform. The development of microbialites was facilitated by a low sedimentation rate, and possibly by increased nutrient level. Only poorly diversified and non-phaceloid pachythecaliines occur in other coral-rich limestones and marls of the Urgonian complex in Bulgaria. The assemblage described is the most remarkable, Early Cretaceous coral community worldwide, with regard to pachythecaliines. Phaceloid pachythecaliines are only more common in the Upper Jurassic rocks, being particularly diversified in the Tithonian-Lower Berriasian [#352](#); tramberk Limestone (Czech Republic) and its equivalent in the Polish Outer Carpathians. However, their sedimentary context differs from that described for the corals of the Emen Formation.

88293 <SOURCE>Acta Palaeontologica Sinica 51, 3: 290-307.</SOURCE>

88294 <ABSTRACT>The described and illustrated scleractinian corals comprise 17 genera and 23 species, including one new species *Stylosmilia xizangensis* sp. nov. and six which are specifically indeterminable. Amongst them are: *Heliocoenia* aff. *etalloni*, *H. bandukidzea*, *Heliocoenia orbigny*, *Isastraea bernensis*, *Axosmilia sessilis*, *Cryptocoenia octosepta*, genus *Dermosmilia* with *D. laxata* and *D. cf. laxata*, *Thecosmilia trichotoma*, *Thamnasteria coquandi*, *Thamnasteria mettensis*, *Mitrodendron ogilvieae*, *Rhipidogyra flabellum*, *Isastraea rariseptata*, *Latiastraea pakongensis*, *Mitrodendron yilashanensis*. Taken as a whole, this coral fauna indicates a Late Jurassic age. It bears a close relationship with those of Europe (Portugal, France, Germany, Switzerland, Poland, Czech, Romania, Ukraine and Greece), with Central South Asia (Azerbaijan, Georgia), and with parts of Gondwana (Madagascar and India).

88305 <TITLE>Fossil corals from the Gulf of California, Mexico: still a depauperate fauna but it bears more species than previously thought.

- 88306 </TITLE>
<SOURCE>Proceedings of the California Academy of Sciences 4, 59, 12:
503-519.</SOURCE>
- 88307 <ABSTRACT>A new collection of fossil hermatypic corals from the late
Miocene Imperial Formation, the early Pliocene San Marcos Formation,
the middle to late Pliocene Carmen Formation and the Pleistocene, Gulf
of California, Mexico, has yielded four undescribed species *Siderastrea*
sp., cf. *Placosmilia* sp., *Favia* sp. 1., and *Favia* sp. 2. Additionally,
new occurrences of the previously described *Pocillopora damicornis*
(Linnaeus 1758), *Pocillopora verrucosa* (Ellis and Solander 1786),
Pocillopora meandrina Dana 1846, *Gardineroseris planulata* (Dana 1846),
Pavona clavus (Dana 1846), *Porites lobata* Dana 1846, *Diploria*
sarasotana Weisbord 1974 as well as *Dichocoenia eminens* Weisbord 1974,
are reported. The fauna occurs either in low-angle ramps or flat lying
terraces of variable extension. Most outcrops are small, and
reminiscent of more extensive deposits usually deposited on open,
exposed, high-energy environments. However, well reserved units
deposited on protected embayments are also present. Except at Isla
Coronados and La Ventana where multiple coral terraces occur, coral
bearing units represent single spatio-temporal growth episodes. The
present analysis shows that hermatypic coral fauna between late Miocene
to late Pleistocene in the Gulf of California is still depauperate;
nonetheless it bears many more species than previously thought.

- 88320 <ABSTRACT>A new collection of fossil reef corals from the late Miocene
Imperial Formation, the early Pliocene San Marcos Formation, the middle
to late Pliocene Carmen Formation, and the Pleistocene, Gulf of
California, Mexico, has yielded four new species *Siderastrea annae* n.
sp., *Placosmilia? aliciae* n. sp., *Favia maitreyiae* n. sp., and *Favia*
tulsidasi n. sp. Additionally, new occurrences of the previously
described *Pocillopora damicornis* (Linnaeus, 1758), *Pocillopora*
verrucosa (Ellis & Solander, 1786), *Pocillopora meandrina* Dana,
1846, *Gardineroseris planulata* (Dana, 1846), *Pavona clavus* (Dana,
1846), *Porites lobata* Dana, 1846, *Diploria sarasotana* Weisbord, 1974,
as well as *Dichocoenia eminens* Weisbord, 1974, are reported.
Morphometric analysis failed to distinguish between *S. californica*
Vaughan, 1917, and *S. mendenhalli* Vaughan, 1917, therefore the former
is synonymized with the latter. The fauna occurred either in low-angle
ramps or flat-lying terraces of variable extension. Most outcrops were
small, and reminiscent of more extensive deposits usually formed in
open, exposed, high-energy environments. However, well preserved units
deposited in protected embayments are also present. Except at Isla
Coronados and La Ventana where multiple coral terraces occur, coral
bearing units represent single spatiotemporal growth episodes. The
present analysis shows that the reef coral fauna between late Miocene
to late Pleistocene in the Gulf of California can be considered
depauperate when compared to the Caribbean fauna; nonetheless, it bears
many more species than previously thought.</ABSTRACT>

88345 <SOURCE>Treballs del Museu de Geologia de Barcelona 17: 7-10.</SOURCE>
88346 <ABSTRACT>The Scleractinian coral genus Anisoria Vidal, 1917 is a Late Cretaceous (Campanian - Maastrichtian) coral endemic to the north of the Iberian peninsula. Herein it is reconsidered on the basis of thin sections obtained from one syntype of the type species Anisoria vidali and additional material of the type species from its type locality. This makes it possible to define the fine structure of this coral in greater detail and to state its systematic position more precisely. The genus is comparable to other so-called Meandrinid genera such as Meandroria, Pachygyra and Orbignygyra. The closest relationship exists with Pachygyra, which has a lamellar columella that is lacking in Anisoria.</ABSTRACT>

88357 <TITLE>Systematic revision of the Placocoeniidae (Scleractinia; Late Cretaceous).</TITLE>
88358 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Abhandlungen 261: 195-200.</SOURCE>
88359 <ABSTRACT>The Late Cretaceous coral family Placocoeniidae is revised on the base of the type and topotypic material of the type species of Placocoenia, Astrea macrophthalma Goldfuss, 1826. The types of the type species of genera currently assigned to this family were examined and confirmed or discarded as members of the family. After its revision, the Placocoeniidae contains four genera - Barycora, Columnocaeniopsis, Columnocoenia, and Placocoenia - which are all very similar, if not synonymous. The family ranges from the Coniacian to Maastrichtian. All Jurassic and Early Cretaceous species currently assigned to these genera need to be reclassified to genera of the Columastraenidae because they do not fit into the concept of the Placocoeniidae or its genera.

88370 <TITLE>The Cretaceous corals from the Bisbee Group (Sonora; Late Barremian - Early Albian): introduction and family Aulastreaeoporidae.</TITLE>
88371 <SOURCE>Revista mexicana de ciencias geológicas 28, 2: 254-261.</SOURCE>
88372 <ABSTRACT>The present contribution is the first instalment in a systematic revision of the corals from the Sonoran Bisbee Group (Late Barremian to Early Albian). The article gives a short overview on the lithostratigraphy and outcrops of the study area and reports the corals of the family Aulastreaeoporidae (suborder Rhipidogyrina). The family contains 10 genera, three of which were found in Sonora. Since the genera Aulastreaeopora and Preverastraea were recently systematically revised including the material from the Bisbee Group, the details are not repeated here. For the genus Paraacanthogyra a new species from the Early Albian of the Cerro la Ceja mountain range is reported. This species is the first indication of the genus in the western Hemisphere. It differs from other species of the same genus by its very small calicular diameter.</ABSTRACT>

88384 <SOURCE>Rivista italiana di paleontologia e stratigrafia 117, 2: 347-352.</SOURCE>
88385 <ABSTRACT>Two coral species from the Early Aptian of the Monti d'Ocre area (Abruzzi) originally assigned to the genus Microsaraea Koby, 1889 are revised on the basis of their type material. Both are assigned to the genus Polyphylloseris. They are considered synonymous. The senior synonym, Microsaraea distefanoi Prever, 1909, was formerly assigned to the genus Microsolena and has a wide geographical and stratigraphical distribution. Since Microsaraea distefanoi Prever belongs to a different genus, the citations in the literature of this species are critically reviewed and, where possible, assigned to the proper Microsolena species.</ABSTRACT>

- 88396 <TITLE>Revision of the coral genera Neocoenia and Helladastraea from the Cretaceous of Greece.</TITLE>
- 88397 <SOURCE>Palaeodiversity 4: 7-15.</SOURCE>
- 88398 <ABSTRACT>The two Cretaceous scleractinian coral genera Neocoenia and Helladastraea are revised on the basis of the type material of their respective type species. The type material of the type species of both genera come from the Greek locality Panourgias (former Dremisa) originally dated as Cenomanian in age. Regarding the geological outcrop situation, this age is only valid for part of the samples, which come from different coral bearing layers. Neocoenia is a plocoid form closely related to Columastrea and probably a senior synonym of Stephanaxophyllia. Helladastraea, originally established as a subgenus of Aspidiscus and long-time considered a junior synonym of this genus is indeed very closely related to this genus, but differs by its conical monticules.</ABSTRACT>

- 88410 <SOURCE>Palä ontologische Zeitschrift 86, 1: 15-22.</SOURCE>
- 88411 <ABSTRACT>The very common and species rich Scleractinian genus Actinastrea (family Actinastreaeidae, suborder Archeoceniina) is revised on the basis of the type material of its type species and additional material from the type locality. A lectotype is designated for the type species. It was discovered that Jurassic to Early Cretaceous corals currently assigned to Actinastrea do not fit into the concept of this genus. These species belong to the genus Stelidioseris, which is also revised on the basis of the type of the type species including designating a lectotype. These two genera are distinguished by various characteristics: septal external parts are swollen in Actinastrea but not in Stelidioseris, the costae are confluent in Stelidioseris, but not in Actinastrea, the coenosteum is granulated in Actinastrea, but narrower than in Actinastrea and only with costae in Stelidioseris. Actinastrea is restricted to the Late Cretaceous (Late Turonian - Maastrichtian) whereas Stelidioseris originates in the Jurassic and reaches into the Late Cretaceous, but is less common from the Turonian on.</ABSTRACT>

- 88462 <SOURCE>Geodiversitas 34, 2: 399-407.</SOURCE>
- 88463 <ABSTRACT>The Late Cretaceous Scleractinian family Hemiporitidae (suborder Faviina) is revised on the basis of its type genus and respective type species. The family is characterised by having large trabeculae, compact and strong septa with poor ornamentation at their lateral faces, short and non-confluent costae, a strong lamellar columella, a septothecal wall, and an endotheca made of thick tabulae.

Together with the name-giving genus Hemiporites, the two coral genera Cerionefocoenia Reig Oriol, 1995 and Pachynefocoenia Reig Oriol, 1989 from the Late Cretaceous of Spain are assigned to the family. All genera are revised on the basis of the types of their respective type species. Further genera formerly or currently assigned to the Hemiporitidae family are discussed. The family occurs from the Turonian to Maastrichtian.</ABSTRACT>

88474 <TITLE>Intraspecific variation in the genus Stelidioseris (family Actinastreaeidae, suborder Archeocaeniina, order Scleractinia; Jurassic-Cretaceous).</TITLE>

88475 <SOURCE>Geologica Belgica 15, 4: 382-387.</SOURCE>

88476 <ABSTRACT>The genus Stelidioseris (= Actinastrea s.l.) is one of the most common genera in the Late Jurassic and Early Cretaceous and has a high number of species. Species separation is generally based on calicular dimensions, septal symmetry, and septal number. To obtain better insight into intraspecific variation and results for species separation, systematic measurements of the corals were taken and statistically analysed. As a preliminary study, ten type specimens were selected for analysis. In thin sections a large number of calices (up to 200) were measured, including their diameter, distance and the thickness of the wall and coenosteum. For all values, the arithmetic mean, standard deviation and the coefficient of variation were calculated. In Stelidioseris, the calicular diameter is the character with the lowest variation. The distance of the calicular centres, the thickness of the wall, and the number of calices per a given area show a much higher variation and are therefore less suitable for distinguishing samples within a population or species of different faunas. It was found that about 70% of all values of the lumen diameter fall in the first interval (range of the arithmetic mean ± standard deviation). Hence, the first interval is a good representation for most types of measured values in fossil corals. The results are compared to traditional methods by remeasuring published material. It is concluded that the application of systematic measuring should be extended to other species rich coral genera.</ABSTRACT>

88501 <SOURCE>Revista mexicana de ciencias geológicas 29, 3: 534-550.</SOURCE>

88502 <ABSTRACT>The small Maastrichtian coral fauna of Ocozocoautla (Chiapas, Mexico) is being taxonomically reviewed. In contrast to an older study, the material is examined by preparing thin sections and carrying out systematic measurements to ensure that any comparisons of the material with existing species are of statistical significance. Twelve species in ten genera from the suborders Archeoceniina, Fungiina, Meandrinina, Microsolenina and Poritina are described. The genera *Multicolumnastraea* and *Favioseris* are discussed in detail. One genus and its species are described as new: *Filkornia* is a colonial coral genus with very large calices that belongs to the Late Cretaceous family *Felixaraeidae*. All species are colonial corals from a shallow marine environment and many of them are known from localities outside the study area, mostly from the Maastrichtian of Jamaica.</ABSTRACT>

88527 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Abhandlungen 267, 1: 89-116.</SOURCE>
88528 <ABSTRACT>Twenty-six coral species from twenty-one genera of Late Aptian (Early Cretaceous) age are reported from the Helicon Mountains in the Greek province of Boeotia. The studied section close to the village Aliartos includes mainly coarse, massive limestone-conglomerates with a relatively high amount of lithoclasts and carbonatic intraclasts. Most of the intraclasts originate from reefal limestones of similar environments and age. The fauna encompasses typical Early Cretaceous elements of the suborders Archeoceniina, Faviina, Fungiina, Heterocoeniina, Meandrinina, Microsolenina, and Stylinina. The range of two genera has changed - the first occurrence of Adelastrea Reuss, 1854, and Pachyphyllia Alloiteau, 1957, were assigned to the Late Aptian, unlike the Turonian as considered earlier. The fauna shares species with localities worldwide, and their ages mainly range from Barremian to Early Albian. In contrast to very common Early Aptian coral faunas, Late Aptian faunas are rare. The present fauna helps to understand relationship to Albian and Cenomanian faunas.</ABSTRACT>

88540 <SOURCE>Palaeobiodiversity and Palaeoenvironments 93, 1: 1-43.</SOURCE>
88541 <ABSTRACT>A species rich hermatypic coral fauna from the late Early Albian (Mammillatum Zone) from Padern (Les Corbieres, Aude, France) is taxonomically revised. The fauna encompasses 45 species in 24 genera. Genera of the suborders Faviina and Microsolenina dominate, followed by genera of the suborders Stylinina and Fungiina. The suborders Caryophylliina, Fungiina, Heterocoeniina, Meandrinina and Rhipidogyrina are represented by only a few genera. One species of the genus Parnassomeandra is described as new. The hitherto poorly known genera Trochoseropsis and Cyathophoropsis are supported with new material and described and depicted in greater detail. The overall faunal composition is comparable with Aptian to Early Albian coral faunas of the same region and facies, however, the fauna shows some exotic elements that persisted into the Late Cretaceous. Most species are known from Barremian to Albian faunas of the Western Atlantic, the Aptian of the Central Tethys and the Albian Boreal South England Basin.</ABSTRACT>

88591 <TITLE>Taxonomy and distribution of the Early Cretaceous coral genus Actinastraeopsis.</TITLE>
88592 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Abhandlungen 269, 2: 189-202.</SOURCE>
88593 <ABSTRACT>The poorly known Early Cretaceous coral genus Actinastraeopsis is revised on the basis of available type material. It includes six species (Cladophyllia birleyoe Gregory, 1899; Thecosmilia catalaunica Angelis d‘Ossat, 1905; Enallhelia gracilis Orbigny, 1850; Stylosmilia organisans Orbigny, 1850; Actinastraeopsis phaceloides Sikharulidze, 1977; Actinastraeopsis sp.); most of them were formerly assigned to the genus Cladophyllia. Actinastraeopsis forms phaceloid colonies made of densely packed thin branches. These colonies may reach large dimensions and form bioherms measuring several meters in width and height. Actinastraeopsis specimens show a large variation in their calicular dimensions, whereas the number of septa is regular within colonies and shows little variation. Septal counts and calicular dimensions are mainly used to distinguish species. To cope with variation within Actinastraeopsis species, the available material was systematically measured and statistically analysed. About fifty samples from numerous worldwide localities ranging from the Hauterivian to the Middle Albian were included.</ABSTRACT>

88604 <TITLE>The Cretaceous corals from the Bisbee Group (Sonora; Late Barremian - Early Albian): genus Stelidioseris (Actinastraeidae).</TITLE>
88605 <SOURCE>Paleontologia mexicana 63: 79-89.</SOURCE>
88606 <ABSTRACT>The current work constitutes the second part of the systematic revision of the corals from the Bisbee Group (Late Barremian to Early Albian) and deals with the genus Stelidioseris (Family Actinastraeidae, suborder Archeocaeniina). To distinguish samples within the Sonoran fauna and species of this genus, systematic measurements of the corals were taken and statistically analysed. From the Bisbee Group, six Stelidioseris species are here described and illustrated: S. bellensis, S. hourcqi, S. japonica, S. major, S. ruvida, S. whitneyi. Most of them are common Early Cretaceous species with a wide geographic and stratigraphic distribution.</ABSTRACT>

88617 <TITLE>Early Jurassic corals of the Pamir Mountains - a new Triassic-Jurassic transitional fauna.</TITLE>
88618 <SOURCE>Geologica Belgica 15, 4: 376-381.</SOURCE>
88619 <ABSTRACT>Four microstructural groups of corals representing the orders Scleractinia and Hexanthiniaria are known in the Triassic and in the Early Jurassic of the Tethys realm. In the south-eastern Pamir Mountains, Lower Jurassic corals occur from the Hettangian to Toarcian sediments. Hettangian?-Sinemurian and Sinemurian coral faunas discussed

in this paper come from the Gurumdy and Mynkhajir facies zones. Coral associations are composed of classical Early Jurassic west European and North African (Moroccan) taxa, accompanied by several genera previously unknown in the west Tethys. After the end-Triassic extinction, the Early Jurassic recovery faunas of the Pamir Mountains contain Stylophylloopsis, Eocomoseris, a genus related to Elyastrea, and a large number of Jurassic genera: Ooppelismilia, Archaeosmilia, Archaeosmiliopsis, Stylosmilia, Proaplophyllia, Cylismilia, Intersmilia, Prodonacosmilia, Pachysmilia, Placophyllia and Stephanastrea. More or less fragmented corals and complete skeletons are found in detrital carbonate, oolitic, or micritic limestone facies. Phaceloid growth forms prevail over solitary and massive ones. </ABSTRACT>

88630 <TITLE>Corals from the Tithonian carbonate complex in the Dabrowa Tarnowska-Szczucin area (Polish Carpathian Foreland).</TITLE>

88631 <SOURCE>Annales Societatis Geologorum Poloniae 82: 1-38.</SOURCE>

88632 <ABSTRACT>The studied corals have been collected from cores of boreholes located in the central part of the Polish Carpathian Foreland in the Dabrowa Tarnowska-Szczucin area. The Jurassic complex in this area presents a continuous stratigraphic section from the Upper Callovian to Tithonian, locally passing to the Lower Cretaceous (Berriasian). Its thickness exceeds 1,100m in this area. This complex is composed of marine, mainly shallow-water deposits. The corals occur within the upper part of the Upper Jurassic (Tithonian) deposits, almost entirely within the Swarzew Limestone Formation (= coral-algal limestone formation). This occurrence marks the northernmost extent of Tithonian shallow-water corals in Poland and one of the northernmost in Europe. 42 coral species (among them 14 in open nomenclature) were identified in deposits of this formation. They include two new species: Complexastrea magna and Complexastrea dabroviensis. All taxa, except one, belong to the order Scleractinia. The described assemblage displays a Late Jurassic character. The broader stratigraphic span is assigned to some species, which are quoted from the Middle Jurassic and some species lasted until the Early Cretaceous, Berriasian and/or Valanginian.</ABSTRACT>

88643 <TITLE>Aspidiscus cristatus (Lamarck) from the Cenomanian of wadi Quseib, East Sinai, Egypt.</TITLE>

88644 <SOURCE>Journal of the Palaeontology Society of India 56: 29-37.</SOURCE>

88645 <ABSTRACT>Aspidiscus cristatus (Lamarck) has been described and illustrated from three coral-bearing horizons of the Cenomanian sedimentary succession of wadi Quseib, East Sinai, Egypt. The new specimens show well-preserved internal microarchitectures, which corroborate its assignment to family Latomeandridae Alloiteau, 1952.

The stratigraphic range of *Aspidiscus cristatus* suggests that it can be used as index for the Middle to early Late Cenomanian. Based on the morphology of *Aspidiscus cristatus* and its consistent record, it is suggested here that the coral had a narrow facies range, being adapted to a free mode of life on soft, marly to argillaceous substrate, in low-energy environments subjected to high rates of sedimentation.

88656 <TITLE>Paleobiogeography of scleractinian reef corals: Changing patterns during the Oligocene - Miocene climatic transition in the Mediterranean.</TITLE>

88657 <SOURCE>Earth-Science Reviews 111: 1-24.</SOURCE>

88658 <ABSTRACT>During the Oligocene-Miocene Greenhouse-to-Icehouse climatic transition, the biogeography of reef corals or zooxanthellate-like scleractinian corals was gradually changing from a pan-tropical Tethyan Province in the Eocene to three reef-coral Provinces of the Western Atlantic - Caribbean, Indo-Pacific and Mediterranean. Our REEFCORAL database encompasses updated and homogenized data on paleoenvironmental and systematics of scleractinian corals occurring in the Oligocene and Miocene outcrops from circum-Mediterranean regions, provided by most of relatively recently published data in the literature and by the study of published and unpublished collections of coral specimens from the same area, including the important collections housed at the MNHN (Paris) and our own collections. As there is no validated direct criterion for the identification of the coral-zooxanthellate symbiosis in the fossil record, and considering the difficulty to use the biogeochemical approaches in the context of this study, the subjectivity of the morphological criteria and the relative recent age of the fossil corals we are dealing with, a uniformitarian approach has been used for inferring the symbiotic status of scleractinian genera in REEFCORAL. Among the 158 genera included in our database, 93 can be considered as zooxanthellate and 10 have a doubtful zooxanthellate status. This relatively exhaustive database was used to reconstruct the temporal and spatial distribution of scleractinian corals in the Mediterranean during the Oligocene - Miocene time in order to discuss the interplaying effects of the global cooling at that time, the reorganization of the Tethyan realm resulting from the African, Arabian and Eurasian plate collision and the emergence of the Alpine chains, driving the gradual northward movement of the whole region outside the tropical/subtropical belt. * It is shown that the structure of the Mediterranean z-coral Oligocene - Miocene paleobiodiversity was characterized by many geographically-restricted genera with a moderate to short stratigraphical range and a few long-ranging widespread genera. A major consequence of this structure is that the extinction pattern has proceeded through the preferential extinction of rare-occurrence genera through time. The potential rapid long-distance dispersal of most coral larvae compared to the size of the Oligocene - Miocene Mediterranean, explains why no biogeographical sub provinces can be distinguished for the z-coral fauna. On a local scale, ecological processes tend to sort coral taxa by limiting z-coral development to geographically restricted and discontinuous areas. This accounts for the large amount of geographically-restricted taxa forming the Mediterranean coral fauna. ** The interaction of plate-tectonics, Alpine orogenesis and climate at

local to subregional scales exerts strong controls over the spatio-temporal distribution of z-coral assemblages within the circum-Mediterranean realm. In particular, we suggest that the richness and composition of the Eastern Atlantic coral fauna are indirectly related to the opening and closure of the eastern seaway connection with the Indian Ocean, which controlled the E-W circulation of surface waters and hence the westwards dispersal of pelagic larvae. At the scale of the whole region, the gradual regional climatic change produced by the northwards migration of the entire area, superimposed on the global cooling, appears in large part responsible for the extinction pattern of z-corals through time in the Mediterranean biogeographical Province.</ABSTRACT>

88669 <TITLE>Early Norian (Triassic) corals from the Northern Calcareous Alps, Austria, and the intra-Norian faunal turnover.</TITLE>

88670 <SOURCE>Acta Palaeontologica Polonica 56, 2: 401-428.</SOURCE>

88671 <ABSTRACT>The first description of early Norian coral fauna from the Northern Calcareous Alps (Dachstein Plateau and Gosaukamm), Austria, is presented: 31 scleractinian species from 24 genera (including three corals not formally determined), and three hexanthinarian species belonging to two genera. The stratigraphical position of the main part of the fauna discovered in the South Dachstein Plateau at the Feisterscharte is determined by means of the conodont *Epigondolella quadrata* (Lacian 1); single finds are from the horizons with *Epigondolella triangularis* and *Norigondolella navicula* (Lacian 3), and one close to the horizon with *Epigondolella cf. multidentata* (Alaunian 1). Rare corals from the Gosaukamm are from the Lacian 1 and Alaunian. Five species are described as new: *Retiophyllia vesicularis*, *Retiophyllia aranea*, *Margarosmia adhius*, *Hydrasmilia laciana*; one new genus and species from the family Coryphylliidae, *Margarogyra hirsuta*; one new genus and species, *Thamnasterites astreoides*, cannot be assigned to a family. Two hexanthinarian species, *Pachysolenia cylindrica* and *Pachydendron microthallos*, known exclusively from the Tethyan lower Norian, represent stratigraphically valuable species. Regularly porous coral from the family Microsolenidae, *Eocomoseris*, which up to now has only been known from the Jurassic and Cretaceous, is here identified from the Triassic strata (originally described as *Spongiomorpha* [*Hexastyloopsis*] *ramosa*). Predominant taxa show solitary and phaceloid (pseudocolonial) growth forms and an epithecal wall; pennules-bearing corals are common. Carnian genera and genera typical of the Lacian and Lacian-early Alaunian prevail; a hydrozoan genus *Cassianastraea* has also been encountered as well as a scleractiamorph coral, *Furcophyllia septafindens*. The faunal composition contrasts with that of well known late Norian-Rhaetian ones, the difference being observed not only at the generic but also at the family level. The post-early Norian change in coral spectrum documents the turnover of the coral fauna preceding that at the Triassic/Jurassic boundary.</ABSTRACT>

88682 <TITLE>Upper Triassic Corals from Nevada, Western North America, and the Implications for Paleocology and Paleogeography.</TITLE>
88683 <SOURCE>Journal of Paleontology 87, 5: 934-964.</SOURCE>
88684 <ABSTRACT>Late Carnian-early Norian corals from the Luning and Osobb formations in west-central Nevada represent an important Late Triassic fauna for understanding the paleocology and the paleogeography of the eastern Panthalassa region during Late Triassic time. The corals occur in bedded limestone representing biostromes and patch reefs and their composition presages the important global changeover of faunas of the intra-Norian interval. A taxonomic analysis of over 60 specimens reveals a majority of colonial corals ranging from cerioid, astreoid (i.e., cerioid-plocoid lacking walls), meandroid and thamnasterioid types. Surprisingly, remnants of the original aragonite microstructure remain in some specimens, allowing a better comparison with more remote Tethyan corals. In total, 14 genera have been identified from Nevada while two genera remain undetermined. The fauna is composed of species considered typical of both the North American Cordillera and cratonal South America. The following genera and species are new and endemic to the Americas: Khytrastrea silberlingi and K. cuifiamorpha, Flexastrea serialis, Nevadoseris punctata, Areaseris nevadaensis and a new genus Minasteria (with Astrocoenia shastensis Smith, 1927 as type species). Likewise are the new species: Margarogyra silberlingi and Curtoseris dunlapcanyonae. Genera Meandrovolvezia, Margarogyra, Ceriostella, Ampakabastraea, Retiophyllia, Distichomeandra, Curtoseris, Thamnasteria and Astraeomorpha provide important links to the former Tethys province. The revised coral fauna changes previous views of the close taxonomic similarity with the Tethys, instead producing a paleogeographic pattern emphasizing a much greater degree of endemism. This pattern emphasizes the isolation of Nevada from the Tethys and the similarities with some outboard terranes of the Cordillera.</ABSTRACT>

88695 <TITLE>Constraints on the formation of colonies of the extant azooxanthellate scleractinian coral Dendrophyllia arbuscula.</TITLE>
88696 <SOURCE>Lethaia 45, 1: 62-70.</SOURCE>
88697 <ABSTRACT>Scleractinia display a variety of growth forms, whether zooxanthellate or azooxanthellate, as the consequence of the combined effects of both intrinsic and extrinsic factors. New modules arise in colonial corals through asexual reproduction, including budding and division. The azooxanthellate, branching dendrophylliid Dendrophyllia arbuscula van der Horst 1922, is a good species to investigate intrinsic regularities in budding, because: (1) the lateral corallites always occur in the vicinity of four primary septa, excluding the two directive primary septa; (2) the two directive septa in lateral corallites tend to be oriented almost perpendicular to the growth orientation of parental corallites; (3) the lateral corallites grow more-or-less diagonally upwards; and (4) these regularities are retained from the axial to the derived lateral corallites during colony growth. Accordingly, a colony of apparently complex dendroid corals is formed according to certain universal rules that apply to successive

generations of corallites. The presence of two opposite sectors in which budding does not occur seems to be common to other azooxanthellate scleractinian families. Regularities, other than the orientation of the directive septa, are also commonly found at least in other azooxanthellate dendrophylliid genera. These regularities suggest the presence of strict developmental constraints on the asexual reproduction of the scleractinia, both extant and extinct. These regularities by azooxanthellate scleractinians, as one of the representative colonial metazoan groups, provide us with fundamental data with which we can understand how colonies are constructed.

88708 <TITLE>Regularity and polarity in budding of the colonial scleractinian Dendrophyllia ehrenbergiana: consequences of radio-bilateral symmetry of the scleractinian body plan.</TITLE>

88709 <SOURCE>Lethaia 45, 4: 586-593.</SOURCE>

88710 <ABSTRACT>Regularities and polarity in budding of the azooxanthellate scleractinian Dendrophyllia ehrenbergiana were examined with the aim of understanding the developmental constraints on the formation of colonies. Its mode of budding, in light of the orientations of directive septa of offsets and the inclination angle of budding, is consistent with that of other dendrophyllids; however, the offsets of D. ehrenbergiana only occur near the two primary septa on the convex side of individual corallites, showing a plane of bilateral symmetry with a distinct polarity. These regularities and polarity are seen in the axial and its derived corallites throughout growth. Of note, the polarity at individual corallites is clearly reflected in subsequent colony growth by the branching pattern and corallite number. These characteristics imply the presence of radio-bilateral symmetrical constraints on the asexual reproduction of the Scleractinia and give us invaluable clues to the understanding of shape-making mechanisms of marine modular organisms.</ABSTRACT>

88721 <TITLE>Regularity in budding mode and resultant growth morphology of the azooxanthellate colonial scleractinian Tubastraea coccinea.</TITLE>

88722 <SOURCE>Coral reefs 31, 1: 67-74.</SOURCE>

88723 <ABSTRACT>Scleractinia exhibit a variety of growth forms, whether zooxanthellate or azooxanthellate, according to factors that control asexual reproduction and ensuing coral growth. The azooxanthellate branching scleractinian Dendrophyllia arbuscula shows regular modes of budding in terms of the locations of budding sites, the orientations of directive septa, and the inclination angle of budding throughout colonial growth. This study reports that such regularities are also found in the apparently different growth form of the massive dendrophylliid Tubastraea coccinea, which shows the following growth

features: (1) the offsets (lateral corallites) always occur near four primary septa, except the two directive primary septa, meaning that the lateral corallites do not appear in the sectors of the two directive septa; (2) the two directive septa in lateral corallites tend to be oriented subperpendicular to the growth direction of the parental corallites; (3) the lateral corallites grow approximately diagonally upwards; and (4) these regularities are seen in the axial and derived lateral corallites among all generations during colony growth. Large differences in growth form are found between the branching *D. arbuscula* and massive *T. coccinea*, irrespective of the presence of specific regularities. It is likely that subtle modifications of certain parameters (e.g., budding interval, branch length, corallite size, and inclination angle of lateral corallites) have a strong effect on the overall growth morphology. A precise understanding of such regularities, which occur regardless of generation or taxonomic position, would contribute to understanding the "shape-controlling mechanism" of corals, which are an archetypal modular organism.

88734 <TITLE>Regularity in budding mode and resultant growth morphology of the azooxanthellate colonial scleractinian *Cyathelia axillaris*: effective and adaptive ways of utilizing habitat resources.</TITLE>

88735 <SOURCE>Paleontological Research 16, 3: 252-259.</SOURCE>

88736 <ABSTRACT>Azooxanthellate coral species obtain nutrients by themselves, retaining their colonial growth forms independently of other species. This study examines the regularity of budding in the bushy, azooxanthellate scleractinian oculinid *Cyathelia axillaris* in order to identify the developmental constraints on colony formation and the ecological significance of colonial forms. The sympodial form of *C. axillaris* develops its bushy morphology by repeated dichotomous branching without clear axial corallites. The regularities in budding process are as follows: (1) in most cases, two buds originate simultaneously on opposite sides of medially constricted corallites near two parental second-order septa at individual distal ends; (2) the two directive septa of lateral corallites are oriented almost perpendicular to the directive septa of the immediate parental corallites; (3) the lateral corallites grow more or less diagonally upwards; and (4) these regularities remain valid from parental to derived lateral corallites throughout growth. Thus, apparently complex, threedimensional colonies with numerous offsets are formed according to certain rules, irrespective of the generation of individual corallites. The strict developmental constraints and the subtle modifications on asexual reproduction greatly affect the colonial growth that is unique to *C. axillaris*, for which the regularities in budding are effective and adaptive ways of utilizing limited resources (i.e., growth spaces and nutrients).</ABSTRACT>

88747 <TITLE>Intrinsic constraints on sympodial growth morphologies of azooxanthellate scleractinian coral *Dendrophyllia*.</TITLE>
88748 <SOURCE>Plos One 8, 5; doi: 10.1371/journal.pone.0063790</SOURCE>
88749 <ABSTRACT>Background Asexual increase occurs in virtually all colonial organisms. However, little is known about the intrinsic mechanisms that control asexual reproduction and the resultant morphologies of colonies. Scleractinian corals, both symbiotic (zooxanthellate) and non-symbiotic (azooxanthellate) corals are known to form elaborate colonies. To better understand the growth mechanisms that control species-specific type of colony in azooxanthellate dendrophyllid scleractinian corals, we have studied details of the budding pattern in the sympodial colonies of *Dendrophyllia boschmai* and *Dendrophyllia cribrosa*. Principal Findings Budding exhibits the following regularities: (1) the two directive septa of offset corallites are oriented almost perpendicular to the growth direction of parent corallites; (2) offsets generally occur in either of the lateral primary septa that occur on one side of a corallite; the individuals thus show a definite polarity with respect to the directive septa, and only when branching dichotomously offsets occur in both primary septa; (3) the lateral corallites grow more-or-less diagonally upwards; and (4) the regularities and polarities are maintained throughout growth. Given these regularities, *D. boschmai* grows in a zigzag fashion by alternately budding on the right and left sites. In contrast, *D. cribrosa* grows helically by budding at a particular site. Conclusions / Significance The strict constraints on budding regularities and shifts in budding sites observed in the sympodial growth forms of corals greatly affect resulting morphologies in azooxanthellate coral colonies. A precise understanding of these intrinsic constraints leads to a fundamental comprehension of colony-forming mechanisms in modular organisms.</ABSTRACT>

88760 <TITLE>Norian to Rhaetian scleractinian corals in the Ferdows patch reef (Nayband Formation, East Central Iran).</TITLE>
88761 <SOURCE>Journal of Paleontology 86, 5: 801-812.</SOURCE>
88762 <ABSTRACT>The Nayband Formation is one of the best known sedimentary units in central Iran. The type section consists of a thick succession of shale, siltstone, reef limestone and sandstone that is subdivided into five distinct members: Gelkan, Bidestan, Hoz-e-Sheykh, Howz-e-Khan and Qadir. Abundant and well-preserved framework-building scleractinian corals are included among the macrofossils of the Nayband Formation; these corals characterize the formation and are the subject of this study. The Hassan-Abad section, located in northeast Iran in Lute Block (northwest of Ferdows city), was chosen for detailed study and sampling. Analysis of sedimentary lithofacies and faunal assemblages in the Bidestan and the Howz-e-Khan members indicate both biostromal and biohermal characters for the former shallow-water patch reefs and support a Norian to Rhaetian age. The useful biostratigraphic hydrozoan *Heterastridium conglobatum* was studied along with 14 taxa of scleractinian corals: *Stylophyllopsis rudis*, *Distichophyllia norica*, *Paradistichophyllum dichotomum*, *Retiophyllia frechi*, *Retiophyllia norica*, *Retiophyllia robusta*, *Chondrocoenia schafhaeutli*, *Chondrocoenia*

ohmanni, *Astraeomorpha crassisepta*, *Astraeomorpha confusa*, *Astraeomorpha minor*, *Procycolites triadicus*, *Pamiroseris rectilamellosa*, and *Eocomoseris ramosa*. These fossils clarify the stratigraphy of the Nayband Formation, as well as provide new information on the patch reefs and the framework constructors of these reefs.

88773 <TITLE>Morphologic Variation in *Manicina areolata* (Cnidaria, Scleractinia) from the Pleistocene of South Florida.</TITLE>

88774 <SOURCE>Journal of Paleontology 84, 3: 505-517.</SOURCE>

88775 <ABSTRACT>Environmental variability exerts a substantial control on massive, free-living, colonial corals such as *Manicina areolata*, influencing their shape and size as well as other characters, such as base morphology and colline complexity in meandroid forms. This species is well adapted for life in shallow, wave-swept waters due to its self-righting capabilities. Two different ecophenotypes of *M. areolata*, as defined by overall shape and base morphology, are present in two approximately coeval Pleistocene localities (PBA Quarry and Holey Land Canal) in southern Florida. These differences reflect adaptation to two depositional settings. Corallum size, shape, and oral complexity allow clear differentiation between these two environments. Greater corallum size, as primarily manifested by significantly greater height, tends to accompany increased grain size. The basal area and weight per cm² of the coralla appear to be primary limiting factors in *M. areolata*'s growth by controlling the coral's ability to self-right after overturning or causing sinking into less cohesive substrates. Complexity of confluent corallites increases with increasing size and colony volume. Thus, complexity of valley and colline patterns on the oral surface increases as a function of base area, so that collines developed on smaller, soft-substrate-inhabiting colonies are characteristically less complex than are those of larger, higher colonies. These complexities and variation in shape are apparently related to environmental conditions, predominantly substrate, water depth, and physical energy, resulting in recognizable ecophenotypes.</ABSTRACT>

88786 <TITLE>Late Cretaceous scleractinian corals from the rocky shore of Ivö Klack, southern Sweden, including some of the northernmost zooxanthellate corals.</TITLE>

88787 <SOURCE>Cretaceous Research 32: 259-263.</SOURCE>

88788 <ABSTRACT>A relatively low diversity coral fauna comprising eight zooxanthellate, three azooxanthellate, and one unidentified species is described from a Late Cretaceous rocky shore at Ivö Klack, southern Sweden. All species, except the solitary azooxanthellate *Paracyathus?* sp., are represented by one or two specimens only,

indicating low preservation potential similar to the aragonite-shelled gastropod fauna from the same locality. The fauna comprises one out of two northernmost zooxanthellate forms known and adds important environmental information to the fauna and depositional conditions of the rocky shore at Ivö Klack.</ABSTRACT>

88799 <TITLE>The ancient evolutionary origins of scleractinia revealed by azooxanthellate corals.</TITLE>

88800 <SOURCE>BMC Evolutionary Biology 11, 316: 1-10.</SOURCE>

88801 <ABSTRACT>* Background. scleractinian corals are currently a focus of major interest because of their ecological importance and the uncertain fate of coral reefs in the face of increasing anthropogenic pressure. Despite this, remarkably little is known about the evolutionary origins of corals. The Scleractinia suddenly appear in the fossil record about 240Ma, but the range of morphological variation seen in these Middle Triassic fossils is comparable to that of modern scleractinians, implying much earlier origins that have so far remained elusive. A significant weakness in reconstruction(s) of early coral evolution is that deep-sea corals have been poorly represented in molecular phylogenetic analyses. ** Results. By adding new data from a large and representative range of deep-water species to existing molecular datasets and applying a relaxed molecular clock, we show that two exclusively deep-sea families, the Gardineriidae and Micrabaciidae, diverged prior to the Complexa/Robusta coral split around 425 Ma, thereby pushing the evolutionary origin of scleractinian corals deep into the Paleozoic. *** Conclusions. The early divergence and distinctive morphologies of the extant gardineriid and micrabaciid corals suggest a link with Ordovician "scleractiniamorph" fossils that were previously assumed to represent extinct anthozoan skeletonized lineages. Therefore, scleractinian corals most likely evolved from Paleozoic soft-bodied ancestors. Modern shallow-water Scleractinia, which are dependent on symbionts, appear to have had several independent origins from solitary, non-symbiotic precursors. The Scleractinia have survived periods of massive climate change in the past, suggesting that as a lineage they may be less vulnerable to future changes than often assumed.</ABSTRACT>

88812 <TITLE>Pleistocene to Recent scleractinian deep-water corals and coral facies in the Eastern Mediterranean.</TITLE>

88813 <SOURCE>Facies 57: 579-603.</SOURCE>

88814 <ABSTRACT>Recent investigations of the Eastern Mediterranean Sea

carried out during the GECO cruise with RV Urania provided a substantial number of new cold-water coral (CWC) records, including branching and solitary scleractinian species. These new sites are located along steep escarpments and on topographic highs along the margins of Crete, Karpathos, and Rhodes. The majority of the corals represent fossil occurrences, predominantly Late Pleistocene assemblages. Our research documents that the Eastern Mediterranean Basin has been colonized by CWC at favorable times during the Last Glacial, in particular during the Younger Dryas. *Schizocyathus fissilis* is reported for the first time for the Mediterranean, while the finding of *Ceratotrochus magnaghii* represents the first record for the Eastern Mediterranean. Various coral facies occur on the southerly island slopes of Crete, Karpathos, and Rhodes, including hardgrounds and loose skeletal sediments. Hardgrounds occur on steep topographies between ca. 500 and 1,700m, and can conveniently be subdivided as (1) *Neopycnodonte-Desmophyllum* framestone, (2) *Desmophyllum-Caryophyllia* framestone, (3) *Madrepora-Lophelia* rudstone, (4) Pelagic mudstone and wackestone, and (5) siliciclastic-carbonate conglomerate and breccia. Unconsolidated skeletal sediments containing corals mainly occur on gentler topographic situations between ca. 140 and 600m and can be subdivided as: (A) *Lophelia-Madrepora* rubble, (B) *Dendrophyllia* rubble, (C) *Stenocyathus* rubble, (D) *Caryophyllia calveri* rubble, and (E) fine-grained sediment with octocoral axes. Many of these facies types are also present in the western part of the Mediterranean and have fossil representatives from the Pleistocene to the Recent. Radiocarbon dating (AMS-14C) reveals Younger Dryas ages between 12.4 and 12.0 ka cal BP for *Lophelia pertusa* and *Madrepora oculata*. *Desmophyllum dianthus* occurs during the Last Glacial Maximum (21.8 ka cal BP) and the Younger Dryas (11.7 ka cal BP), as well as during the Late Holocene and subrecent times (4.4-0.6 ka cal BP). *Caryophyllia sarsiae* occurs during the Late Glacial (15.5 ka cal BP), while *Caryophyllia calveri* occurs during the Early Preboreal (10.8 ka cal BP). The ages for the framework-constructing corals *L. pertusa* and *M. oculata* are coherent with their temporal predominance during the Younger Dryas in other parts of the Mediterranean. </ABSTRACT>

88825 <TITLE>Asexual reproduction of Pliocene solitary scleractinian coral *Truncatoflabellum*: a morphological and biometric study.</TITLE>

88826 <SOURCE>Journal of Paleontology 86, 2: 268-272.</SOURCE>

88827 <ABSTRACT>*Truncatoflabellum* has been considered a free-living genus that exhibits both sexual and asexual phases; divided lower coralla (anthocauli) are specialized for asexual reproduction by transverse division through a decalcification process, whereas the upper coralla (anthocyathi) only undertake sexual reproduction, in a life-cycle strategy that includes a distinct alternation of generations. However, little evidence has been presented to support this idea of its life cycle. We elucidate the life mode of *Truncatoflabellum* by identifying key fossil characters (e.g., multiple rejuvenations and decalcification records just beneath lateral spines) and statistically analyzing the size distributions of over 500 individual coralla. Results of those morphological and biometric analyses clearly indicate alternation of generations in the life cycle of *Truncatoflabellum*.</ABSTRACT>

88838 <TITLE>Attachment structures in Rhizotrochus (Scleractinia): macro- to microscopic traits and their evolutionary significance.</TITLE>
88839 <SOURCE>Lethaia 46, 2: 232-244.</SOURCE>
88840 <ABSTRACT>Marine sessile benthic organisms living on hard substrates have evolved a variety of attachment strategies. Rhizotrochus (Scleractinia, Flabellidae) is a representative azooxanthellate solitary scleractinian coral with a wide geographical distribution and unique attachment structures; it firmly attaches to hard substrates using numerous tube-like rootlets, which are extended from a corallum wall, whereas most sessile corals are attached by stereome-reinforced structures at their corallite bases. Detailed morphological and constructional traits of the rootlets themselves, along with their evolutionary significance, have not yet been fully resolved. Growth and developmental processes of spines in Truncatoflabellum and rootlets in Rhizotrochus suggest that these structures are homologous, as they both develop from the growth edges of walls and are formed by transformation of wall structures and their skeletal microstructures possess similar characteristics, such as patterns of rapid accretion and thickening deposits. Taking molecular phylogeny and fossil records of flabellids into consideration, Rhizotrochus evolved from a common free-living ancestor and invaded hard-substrate habitats by exploiting rootlets of spines origin, which were adaptive for soft-substrate environments.</ABSTRACT>

88865 <SOURCE>Journal of Paleontology 85, 6: 1042-1051.</SOURCE>
88866 <ABSTRACT>The Late Cretaceous white chalk of the Isle of Rügen, northeastern Germany, yields a highly diverse marine floral and faunal assemblage with more than 1,400 described species, including pennatulacean corals. All the new collected material, composed of fragments of the axial rods, belongs to 'Graphularia' quadrata Voigt, 1958, which was revised, and a new species, 'Graphularia' rugia. Analyses of the microstructure of axial rods of modern and fossil sea pens facilitate the discussion of the systematic relationships of the fossil material. 'Graphularia' quadrata shows an affinity to the Funiculinidae, whereas the new species 'Graphularia' rugiaresembles the axial structure of the Pennatulidae.</ABSTRACT>

88890 <TITLE>Unusually Preserved Metaconularia manni (Roy, 1935) from the Silurian of Iowa, and the Systematics of the Genus.</TITLE>
88891 <SOURCE>Journal of Paleontology 84, 1: 1-31.</SOURCE>
88892 <ABSTRACT>The welton Member of the Scotch Grove Formation at Shaffton Quarry, near Camanche, Iowa, is about 427 Ma old and contains numerous metaconulariid specimens, many of which are preserved in apex-downward orientation. Some of these show an unusual, splayed, "Maltese cross" configuration. Apex-downward configurations suggest rapid burial, consistent with the soft part preservation known in other taxa from this locality. The abundance of Metaconularia at Shaffton Quarry, and of topotype specimens of M. aspersa, the generic type species, permits evaluation of the degree of individual and intracollectional variation in peridermal ornament. Variation within and among individuals precludes reliance on ornamental differences in species differentiation in most cases. In view of these results we assign all Shaffton specimens to Metaconularia manni (Roy, 1935), and revise Metaconularia based on its type material from Europe and other material from Europe and North America. An exploratory phylogenetic analysis highlights aspects of character distribution within the genus, but the small number of characters states and possible taphonomic influences upon them limit confidence in the clade topology. Subgroups within the genus are characterized by larger, discoidal papillae, and by strong transverse corrugation and sinuous rows of smaller papillae. The genus

itself comprises those conulariids with an external ornamentation of simple, round, small papillae, paired internal septae along the midlines, and a thin periderm that was to some degree pliable during life.

88903 <TITLE>Late Ordovician Conulariids from Manitoba, Canada.</TITLE>
88904 <SOURCE>Journal of Paleontology 87, 5: 775-785.</SOURCE>
88905 <ABSTRACT>Six species of conulariids, assigned to four genera, were recovered from the type locality of the Cat Head Member of the Red River Formation in southern Manitoba, Canada. These are middle Katian (Late Ordovician) in age. The most abundant conulariid species from this locality, *Conularia porcella*, is new, and is represented by 21 specimens. Additionally, 28 three-dimensionally preserved micromorphic conulariids, assigned to *Eoconularia* aff. *loculata*, were recovered using acetic acid preparation from limestone samples of late Katian (Late Ordovician) age. These samples had been collected from Churchill, northern Manitoba, by the Geological Survey of Canada's J. B. Tyrrell in 1894. These taxa are unusually abundant for conulariids, which are normally represented by only a few specimens from any given locality, and this abundance may be a reflection of the exceptional preservation at these two localities.</ABSTRACT>

88916 <TITLE>Asymmetry in an Ordovician conulariid cnidarian.</TITLE>
88917 <SOURCE>Lethaia 45, 3: 423-431.</SOURCE>
88918 <ABSTRACT>Conulariids are fossils of the presumed polyps of an extinct scyphozoan cnidarian group. Their cone-shaped skeletons normally show perfect tetradial symmetry. However, in the Ordovician species *Metaconularia anomala* (Barrande 1867) from Drabov (Czech Republic), tetradial symmetry is compromised in three ways: (1) the skeleton often shows torsion; (2) the four sides may vary in width at the same level within one individual; and (3) one side may be deleted to give a triradial skeleton. Almost 2000 specimens were studied in museum collections. About 56% of analysed specimens are twisted in an anticlockwise direction (sinistral) when viewed from the apex towards the aperture, 28% show no torsion, 1% exhibit clockwise torsion (dextral) and the remaining 15% cannot be classified. Maximum measured torsion rate was 1.5°/mm. A significant negative correlation between torsion rate and length suggests that more highly torqued individuals may have survived less well. Almost 5% of individuals show loss of one side for at least part of their lengths. Although many individuals have four sides of equal width, in a significant proportion the sides are of unequal width, up to a maximum / minimum side width ratio of 2 (i.e. widest face twice the width of the narrowest). In the absence of a satisfactory taphonomic model to explain the asymmetries, they are regarded as mirroring asymmetries in the living conulariids,

with the strong preference for sinistral torsion interpreted as an example of a fixed asymmetry that was genetically controlled and heritable. It is speculated that the signalling protein Nodal as well as Hox-like genes were involved in controlling the asymmetries described in *M. anomala*.</ABSTRACT>

88929 <TITLE>The aperture and its closure in an Ordovician conulariid.</TITLE>
88930 <SOURCE>Acta Palaeontologica Polonica 56, 3: 659-663.</SOURCE>
88931 <ABSTRACT>The conulariids, an enigmatic fossil group believed to be of cnidarian (scyphozoan) affinity, have four-sided, acutely pyramidal exoskeletons terminated in apertural closures. To date, three main closure types have been recognised in conulariids (plicated, triangular lappets, and lobate lappets) but the first type is poorly illustrated in the literature. Here we present the first photographic illustration of an unequivocal plicated closure in *Metaconularia? anomala*, based on study of the rich (1700+ specimens) material from the Upper Ordovician of the Prague Basin. This closure is formed by inwardly folded, triangular lappets centred on each of the four faces, with kite-shaped elements centred on the four corners forming a webbing between the lappets. Plicated closures were evidently rare in conulariids and restricted to a few Ordovician species.</ABSTRACT>

88942 <TITLE>Exceptionally preserved conulariids and an edrioasteroid from the Hunsruck Slate (Lower Devonian, SW Germany).</TITLE>
88943 <SOURCE>Palaeontology 53, 2: 403-414.</SOURCE>
88944 <ABSTRACT>Nineteen partial specimens of *Conularia* sp., together with an articulated agelacrinitid edrioasteroid and several discinid brachiopods, occur in close association with a probable biological substrate on a small slab of silty Hunsruck Slate (Lower Devonian, Emsian) from Bundenbach, Germany. Most of the conulariids occur in V-like pairs or in a single cluster of 12 specimens arranged in a fan-like radial pattern. Together with the edrioasteroid and (possibly) brachiopods, the conulariids probably were attached to the substrate in life and then were buried and possibly killed by a single influx of silty mud. The apertural end of many of the conulariids is partially covered by inwardly folded short lappets, which may have closed in response to rapid (but gentle) burial. Rock matrix in the apertural region of the peridermal cavity of nearly all of the conulariids exhibits irregular, variably dense concentrations of pyrite. The concentrations occur almost exclusively within the conulariids, where they probably formed as a result of the decay of retracted conulariid soft parts. Although the concentrations lack clearly defined anatomical features that can be unambiguously homologized with particular anatomical structures of any extant taxon, their form and distribution within the conulariids are consistent with the hypothesis that

- conulariids were polypoid scyphozoans.</ABSTRACT>

- 88955 <TITLE>Life mode of in situ Conularia in a Middle Devonian epibole.</TITLE>
- 88956 <SOURCE>Palaeontology 56, 1: 29-48.</SOURCE>
- 88957 <ABSTRACT>Exceptionally abundant specimens of Conularia aff. desiderata Hall occur in multiple marine obrution deposits, in a single sixth-order parasequence composed of argillaceous and silty very fine sandstone, in the Otsego Member of the Mount Marion Formation (Middle Devonian, Givetian) in eastern New York State, USA. Associated fossils consist mostly of rhynchonelliform brachiopods but also include bivalve molluscs, orthoconic nautiloids, linguliform brachiopods and gastropods. Many of the brachiopods, bivalve molluscs and conulariids have been buried in situ. Conulariids buried in situ are oriented with their aperture facing obliquely upward and with their long axis inclined at up to 87 degree to bedding. Most specimens are solitary, but some occur in v-like pairs or in radial clusters consisting of three specimens, with the component specimens being about equally long or (less frequently) substantially different in length. The compacted apical end of Conularia buried in situ generally rests upon argillaceous sandstone. With one possible exception, none of the examined specimens terminates in a schott (apical wall), and internal schotts appear to be absent. The apical ends of specimens in v-like pairs and radial clusters show no direct evidence of interconnection of their periderms. The apical, middle or apertural region of some inclined specimens abuts or is in close lateral proximity to a recumbent conulariid or to one or more spiriferid brachiopods, some of which have been buried in their original life orientation. The azimuthal bearings of Conularia and nautiloid long axes and the directions in which conulariids open are nonrandom, with conulariids being preferentially aligned between 350 and 50 degree and with their apertural end facing north-east, and nautiloids being preferentially aligned between 30 and 70 degree. Otsego Member Conularia were erect or semi-erect, epifaunal or partially infaunal animals, the apical end of which rested upon very fine bottom sediment. The origin of v-like pairs and radial clusters remains enigmatic, but it is probable that production of schotts was not a regular feature of this animals life history. Finally, conulariids and associated fauna were occasionally smothered by distal storm deposits, under the influence of relatively weak bottom currents.</ABSTRACT>

- 88968 <TITLE>Redescription of Hexaconularia He and Yang, 1986 (Lower Cambrian, South China): implications for the affinities of conulariid-like small shelly fossils.</TITLE>

- 88969 <SOURCE>Palaeontology 53, 1: 191-199.</SOURCE>
88970 <ABSTRACT>Hexaconularia, a Lower Cambrian small shelly fossil (SSF) that has been allied with conulariids and scyphozoan cnidarians, is redescribed and refigured. A salient feature of this monospecific genus is the presence of distinct apical and abapical regions. The apical region probably represents an embryonic shell that apparently lacked a basal attachment structure. Comparisons of this feature with the apical end of the smallest known conulariids and with conulariids terminating in an apical wall (schott) reveal substantial differences in structure and ornamentation. Differences in apical anatomy between conulariids and Arthrochites, possibly the nearest SSF relative of Hexaconularia, are also apparent. Comparisons of Hexaconularia with Punctatus, an SSF taxon showing distinct apical and abapical regions in both posthatching specimens and prehatching embryos, suggest that the early development of Hexaconularia was direct. These results have important implications for hypotheses of a conulariid / scyphozoan affinity for Hexaconularia and its possible SSF relatives, and they suggest that Hexaconularia-bearing strata may yield prehatching embryos of this genus.</ABSTRACT>

88981 <TITLE>Revision of the Hydroid Plumalina Hall, 1858 in the Silurian and Devonian of New York.</TITLE>
88982 <SOURCE>Journal of Paleontology 87, 4: 710-725.</SOURCE>
88983 <ABSTRACT>The feather-shaped Plumalina Hall, 1858 is revised on the basis of new and reexamined specimens from New York. Previously described from Givetian through Famennian deposits, a single compression of P. tenera n. sp. from the Rochester Shale extends the range into the Wenlock, and provides new information regarding Plumalina's biology. We assess the utility of morphologic characters in diagnoses of taxa, and present the first quantitative analysis of fossil hydroids to distinguish P. brevis n. sp. (Frasnian) from other Devonian species. * Plumalina has been compared to plants, graptolites, and octocorals. Some interpretations have proposed affinities among hydrozoans based on colony form and the presence of putative polyp bases. Our analysis shows that, like extant thecate hydrozoans, Plumalina had a delicate, chitinous hydrocaulus with weakly articulated hydrocladia. An assemblage of in situ specimens, steeply inclined relative to the bedding plane in an Ithaca Formation (Frasnian Stage) turbidite, indicates that Devonian species produced sessile, erect colonies attached to a hard substrate, comparable to extant hydroids that feed in currents. Morphometric comparisons between putative Plumalina polyp bases and polyp bases of modern analogues reveal similarities to hydroids in the superfamily Plumularioidea McCrady, 1859. Plumalina is the most abundant fossil hydroid so far reported, and is pertinent to interpretations of the hydrozoan record.</ABSTRACT>

88994 <TITLE>The occurrence of the Hydrozoan genus Cassianastraea from Upper Triassic (Carnian) rocks of Williston Lake, British Columbia, Canada.
</TITLE>
88995 <SOURCE>Journal of Paleontology 85, 1: 29-31.</SOURCE>
88996 <ABSTRACT>Cassianastraea is an enigmatic colonial Triassic cnidarian first described as a coral but subsequently referred to the Hydrozoa. We report here the first occurrence in Canada of fossils we designate as Cassianastraea sp. from the Williston Lake region of British Columbia. The specimens come from older collections of the Geological Survey of Canada, collected in Upper Triassic (Carnian) strata assigned to either the Ludington or Baldonne1 Formations. While well known in reef associations of the former Tethys region, Cassianastraea is relatively rare in North America. The Carnian Baldonne1 Formation contains the earliest coral reefs from the North American craton and we suspect that Cassianastraea sp. also came from this reef association.

</TITLE>
89008 <SOURCE>Acta Palaeontologica Sinica 51, 2: 176-185.</SOURCE>
89009 <ABSTRACT>The coral fauna dealt with in this paper was collected from Xikeer in Jiashi County, Xinjiang, in the western Tarim Basin. The coral-bearing strata are assigned to the middle-lower part of the Kolpingtag Formation, of Lower Llandovery age. Xikeer is the only locality with Early Llandoveryan corals in the Tarim Basin and hence is of considerable palaeobiogeological interest within the Silurian of China as a whole. The coral fauna includes following species: Paleofavosites schmidti Sokolov, P. schmidti borealis Sokolov, Schedohalysites raregonopora sp. nov., Mclodea jiashiensis sp. nov., M. xikeerensis sp. nov., and Kodonophyllum cf. undulatum He and Huang.

89033 <TITLE>Australian Cretaceous Cnidaria and Porifera.</TITLE>
89034 <SOURCE>Alcheringa 35, 2: 241-284.</SOURCE>
89035 <ABSTRACT>Australian Cretaceous sponge and coral faunas are reviewed and increased with new discoveries. The largest new fauna described, from the very thin Maastrichtian Miria Formation, an uncemented chalky marl, in the Carnarvon Basin, Western Australia, includes a poriferan, *Ventriculites* sp., the hydrozoans, *Stylaster* cretaceous sp. nov. and *Astya nielsenii* wells, 1977 originally described from the Eocene of Tonga and the scleractinian corals *Smilotrochus carnarvonensis* sp. nov., *Conotrochus giraliensis* sp. nov., *Parasmilia cyensis* sp. nov., *Palaeopsammia cardabiaensis* sp. nov., *Flabellum miriaensis* sp. nov., *Ballanophyllia acostae* sp. nov., representatives of five genera left in open nomenclature and *Caryophyllia arcotensis* (Forbes, 1846), originally described from south India. The Santonian Gingin Chalk, in the northern Perth Basin, Western Australia has yielded the scleractinian corals *Ceratotrochus ginginensis* (Etheridge 1913), originally assigned to *Coelosmilia* and *Caryophyllia arcotensis* (Forbes, 1846), holdfast structures that probably supported octocorals and the poriferans, *Peronidella*(?) *globosa* (Etheridge 1913) and *Pachyteichisma corrugatus* sp. nov. *Mckenziephyllia accordensis* gen. et sp. nov. is described as the first scleractinian coral (Faviidae) from the Eromanga Basin. It comes from the Albian Allaru Formation in the Barcardine district of central Queensland. *Purisiphonia clarkei* Bowerbank, 1869 is noted from the Aptian wallumbilla Formation as the only known poriferan in the Surat and Eromanga basins.</ABSTRACT>

89085 <TITLE>Early Ordovician shift in reef construction from microbial to metazoan reefs.</TITLE>
89086 <SOURCE>Palaios 26, 02: 106-114.</SOURCE>
89087 <ABSTRACT>The Ordovician is a period when novel reef ecosystems appeared along with new reef constructors and skeletal-dominated reefs. The Lower Ordovician (late Tremadocian) Fenhsiang Formation of the Three Gorges area in South China contains the oldest known bryozoan reefs (lithistid sponge-bryozoan and bryozoan-pelmatozoan reefs) alongside lithistid sponge-microbial reefs. The latter are characterized by the dominance of microbialites that encrusted and bound the frame-building sponges and inter-sponge sediments. In contrast, the lithistid sponge-bryozoan and bryozoan-pelmatozoan reefs are generally characterized by bryozoans that encrusted the frame-building sponges or pelmatozoans and grew to fill the inter-frameworks. These sponges and pelmatozoans did not construct the rigid frameworks unaided; their association with bryozoans enabled the development of small skeletal-dominated reefs with rigid frameworks. Skeletal-dominated reefs, for which frame-constructing and encrusting roles are conspicuous, were largely unknown before the Early Ordovician. The appearance of skeletal organisms (specifically colonial, encrusting bryozoans) enabled the development of skeletal-dominated reefs, which were pioneers in the rise of Middle-Late Ordovician reefs. The Early Ordovician establishment of skeletal-dominated reefs at the earliest stages of the Great Ordovician Biodiversification Event would have created novel niches and biological interactions that further promoted the evolution of reef-building and -dwelling organisms, as well as ensuing reef ecosystems.</ABSTRACT>

89098 <TITLE>The oldest bryozoan reefs: a unique Early Ordovician skeletal framework construction.</TITLE>
89099 <SOURCE>Lethaia 45, 1: 14-23.</SOURCE>
89100 <ABSTRACT>The oldest bryozoan reefs occur in the Lower Ordovician (late Tremadocian) Fenhsiang Formation of the Three Gorges area, South China. These reefs show a unique type of bryozoan (Nekhorosheviella) framework, and were constructed as follows: the first stage involved colonization by lithistid sponges, which acted as a baffler to trap sediments, providing bryozoans with a stable substrate for attachment.

The bryozoans then grew as an encruster on the surfaces of sponges, showing a preferential downwards and lateral growth within the sponge scaffolding to avoid biological and physical disturbance. Finally, these biotic combinations among skeletal organisms formed a rigid, three-dimensional skeletal framework. This mode of bryozoan growth in association with lithistid sponges is remarkable and unique in its growth direction, and the appearance of such reefs, just prior to the widespread development of skeletal-dominated reefs as part of the Great Ordovician Biodiversification Event, provides an excellent example of the earliest attempts by skeletal organisms to form frameworks by themselves. This find significantly enhances our understanding of the initial stages of skeletal-dominated reef evolution and the ensuing development of reefs during the Middle-Late Ordovician. </ABSTRACT>

89111 <TITLE>Early Ordovician reefs in South China (Chenjahe section, Hubei Province): deciphering the early evolution of skeletal-dominated reefs.</TITLE>

89112 <SOURCE>Facies 59, 2: 451-466.</SOURCE>

89113 <ABSTRACT>The Lower Ordovician (late Tremadocian-early Floian) Fenshiang and the overlying Hunghuayuan Formations at the Chenjahe section in the Three Gorges area of Hubei Province, South China, include four types of reef: microbe-dominated (lithistid sponge-stromatolite and lithistid sponge-calcimicrobial) reefs, and skeletal-dominated (lithistid sponge-bryozoan and bryozoan-pelmatozoan) reefs. The microbe-dominated reefs are characterized by the dominance of microbial sediments that encrusted and bound the surfaces of sponges to reinforce the reef frameworks. In contrast, the skeletal-dominated reefs are distinguished by bryozoans that encrusted frame-building sponges and pelmatozoans, and that grew downward to fill the open spaces available within the frameworks. A series of these reefs shows a temporal succession in reef type, with a decline in the lithistid sponge-stromatolite reefs and an increase in the lithistid sponges and receptaculitids within the lithistid sponge-calcimicrobial reefs in the Hunghuayuan Formation, the lithistid sponge-bryozoan reefs are common in both the Fenshiang and Hunghuayuan Formations. These features of the Chenjahe reefs are in marked contrast to other coeval reefs on the Yangtze Platform and elsewhere. skeletal-dominated reefs first developed in the Three Gorges and adjacent areas, located on the central part of the platform. Likewise, lithistid sponges and receptaculitids first developed in the Three Gorges area and then expanded their range. In contrast, stromatolites declined over time, but remained abundant on a marginal part of the platform. The spatial-temporal distributions of these reefs on the Yangtze Platform reflect the initiation of the Great Ordovician Biodiversification Event and its consequences, although influenced by local environmental conditions. The Three Gorges area was a center for the development of skeletal-dominated reefs, which were established earlier here than elsewhere in the world. These reef types and their spatial-temporal successions provide invaluable clues to the earliest evolution of skeletal-dominated reefs and their ensuing development during the Middle-Late Ordovician.</ABSTRACT>

89124 <TITLE>The intrinsic effect of shape on the retrogradation motif and timing of drowning of carbonate patch reef systems (Lower Frasnian, Bugle Gap, Canning Basin, Western Australia).</TITLE>
89125 <SOURCE>Sedimentology 57: 956-984.</SOURCE>
89126 <ABSTRACT>The evolution and architecture of a set of retreating Lower Frasnian patch reef outcrops in the Canning Basin of western Australia were evaluated, and their depositional and stratigraphic contacts spatially recorded using digital surveying tools. The geological data, together with high-resolution digital elevation models, were assembled in three-dimensional visualization and modelling software and subsequently used for building two-dimensional surface models and three-dimensional volumetric models. Numerical data on geometry and shape were extracted from these models and used to quantitatively assess the retrogradation motif of patch reef development. The development of the patch reefs comprises three stages. During stages 1 and 2, the patch reefs exhibited an overall retrogradational escarpment-type configuration displayed by, on average, 60° steep reef-margin walls that lacked the support of coeval slope deposits. The subdivision between stages 1 and 2 is based on minor backstepping reducing less than 10% of the platformtop area. The onset of stage 3 is recognized by stromatolite development fringing reef-margin walls. During stage 3 an aggrading accretionary reefmargin developed, comprising allochthonous and autochthonous slope deposits. [abridged]

89137 <TITLE>The Great Atlasian Reef Complex: An early Cambrian subtropical fringing belt that bordered West Gondwana.</TITLE>
89138 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 294, 3-4: 120-132.</SOURCE>
89139 <ABSTRACT>The so-called Great Atlasian Reef Complex developed during early Cambrian time throughout the Moroccan margin (Souss Basin) of West Gondwana. According to the syndepositional tectonic activity associated with its intracratonic Ediacaran-Cambrian rift, the great reef complex can be subdivided into four major archaeocyathan-microbial reef episodes: * (i) The Atdabanian episode is recorded by a SW-NE-trending, 400km long barrier reef that extended across the western Anti-Atlas. It was controlled by large-scale reactivation of an inherited rifting branch, which resulted in the nucleation and growth of linear reef complexes located along its margin. The interplay of block tilting, sharp modifications in accommodation space, and relative sea-level rise led to a composite retrogradational-aggradational reef systems tract, characterized by archaeocyathan-microbial kalyptate complexes (Tiout Member and Amouslek Formation) that protected stromatolite-dominated, back-barrier environments (lower member of the Igoudine Formation). ** (ii) The western Anti-Atlas recorded an early Botoman reactivation of the same rifting branch that triggered a lateral migration of frame-building centres of carbonate productivity.

As a result, the involved grabens and half-grabens recorded the development of fringing mound complexes (lower Issafen Formation). These occupied some linear intra-platform, deeper depressions capped by marls and shales, whereas laterally equivalent shallower environments recorded the development of patch-reefs and bioherms. *** (iii) The western Anti-Atlas subsequently recorded a late Botoman interval of tectonic quiescence superimposed to a local interval of progradational pulses. This favoured the nucleation of dispersed archaeocyathan-microbial patch-reefs and bioherms. **** (iv) A distinct palaeogeographic area is recognized in the southern High Atlas, where the entire Atdabanian-Botoman interval recorded small-scale, synsedimentary block tilting and high rates of volcanoclastic input. As a result, this sector was characterized by the record of microbial and archaeocyathan-microbial patch-reefs and bioherms, preferentially developed on the uplifted parts of tilted blocks. * The end of reef development and carbonate productivity in the Souss Basin is related to the progradation of siliciclastic depositional systems (Toyonian regression), considered to have caused the collapse of reef communities throughout west Gondwana.</ABSTRACT>

89150 <TITLE>Dynamics of a paleoecosystem reefs associated with oceanic change in carbonate sedimentary regime and carbon cycling (Oxfordian, Swiss Jura).</TITLE>

89151 <SOURCE>Palaios 26, 04: 197-211.</SOURCE>

89152 <ABSTRACT>Herein we report an analysis of an Oxfordian (Upper Jurassic) paleoreef located in the Swiss Jura Mountains. The paleoreef is located in a Middle Oxfordian transitional interval in which sedimentation switched from marl-dominated to carbonate-dominated deposits. The paleoecosystem is composed of four successive fossil communities characterized by microsolenid corals and organisms that specialized in suspension feeding. Carbon isotopes measured from echinoid spine carbonates exhibit a positive trend from ~1.0 ‰ to 2.5 ‰ in δ13C values from the base to the top of the paleoreef. Comparison of δ13C curves with organic matter and belemnites shows different patterns not compatible with a global variation of the carbon cycle. Similar fossil assemblages and stratigraphic sequences identical in age are found along the continental margin of the Tethys-Atlantic Ocean. This biolithostratigraphic succession corresponds to increasing δ13C values of marine and biogenic carbonates, to the transition from marl-dominated to carbonate-dominated deposits, and to the development of carbonate platforms, which together suggest a change in the carbon cycling regime within the Tethys-Atlantic Ocean system.</ABSTRACT>

89163 <TITLE>Microfacies and depositional setting of the Upper Triassic

- mid-oceanic atoll-type carbonates of the Sambosan Accretionary Complex (southern Kyushu, Japan).</TITLE>
- 89164 <SOURCE>Facies 56, 2: 249-278.</SOURCE>
- 89165 <ABSTRACT>The Upper Triassic shallow-water limestones of the Sambosan Accretionary Complex are reconstructed as a remnant of a mid-oceanic atoll-type build-up upon a seamount in the Panthalassan Ocean. The Sambosan atoll-type carbonates and its pedestal were accreted along with deep-water ribbon-chert and related siliceous rocks to the eastern margin of Asia during the Late Jurassic to Early Cretaceous. Studied limestones crop out in southern Kyushu Island, southwest Japan. Although the prevailing and intense deformation during the accretionary process prevents measurement of sections in stratigraphic successions, and sedimentary structures are poorly preserved, microfacies description and foraminifers analysis allow us to speculate the depositional setting of the Sambosan limestones. Seventeen microfacies are distinguished and several foraminifers of Tethyan affinity are identified. Foraminifers indicate a Late Carnian to Rhaetian age. The Tethyan affinity of the macro- and microfaunas suggests that the Sambosan seamount was located presumably in a low- to middle-latitudinal zone of the southern hemisphere during the Late Triassic.</ABSTRACT>

- 89178 <ABSTRACT>Norian-Rhaetian reef-limestone outcrops belonging to the Sambosan Accretionary Complex located near and within Inaba Cave, western Shikoku Island (Japan), are described in detail for the first time. This patch-reef complex is inferred to have formed within an atoll-type carbonate system accumulated over a mid-oceanic seamount surrounded by deep-water radiolarian cherts in the Panthalassic Ocean during the Late Triassic. Because most Upper Triassic reef studies are from the former Tethys Ocean, counterparts from the Panthalassic Ocean, such as this study, are fundamental in resolving sedimentological, palaeontological and palaeobiogeographical issues related to Late Triassic reefs. The microfacies, palaeontology and palaeoecology of the Inaba reef limestones were investigated. The reef-boundstone facies is characterised by abundant coralline sponges that, in association with microbial crusts, constitute the main framebuilders. Some phaceloid and/or dendroid corals occur, but these groups are poorly represented, as are algae. Microproblematica and foraminifers exhibit rich associations, acting as secondary reef builders and/or reef dwellers. The surrounding setting comprises biotrital sponge-coral rudstone and well-preserved megalodont rudstone-floatstone. The sedimentary contact between reef and lagoon facies is observed for the first time within Inaba Cave. Important similarities with the coeval Upper Triassic reefs of the southern classic Peri-Tethys area and especially with the Omani seamounts are recognised, suggesting a more southern-hemisphere origin for Upper Triassic Japanese reefs than predicted by previous reef studies.</ABSTRACT>

89189 <TITLE>Early Silurian (Aeronian) East Point Coral Patch Reefs of Anticosti Island, Eastern Canada: First Reef Recovery from the Ordovician/Silurian Mass Extinction in Eastern Laurentia.</TITLE>
89190 <SOURCE>Geosciences (MDPI) 2: 64-89; Basel.</SOURCE>
89191 <ABSTRACT>An extensive late Aeronian patch reef swarm outcrops for 60-70 km on Anticosti Island, eastern Canada, located in the inner to mid-shelf area of a prominent tropical carbonate platform of southeastern Laurentia, at 20°-25° S paleolatitude of the southern typhoon belt. This complex, described here for the first time, includes more than 100 patch reefs, up to 60-80 m in diameter and 10 m high. Reefs are exposed three-dimensionally on present-day tidal flats, as well as inland along roads and rivers. Down the gentle 1°-2° paleoslope, the reefs grade into coral-sponge biostromes, and westerly they grade into inter-reef or deeper 'crinoidal meadow' facies. The reef builders were dominantly tabulate and rugose corals, with lesser stromatoporoids. Other components include crinoids, brachiopods, green algae (especially paleoporellids), and encrusting cyanobacteria: reefs display some of the earliest known symbiotic intergrowths of corals and stromatoporoids. Reefs were variably built on a base of crinoidal grainstones, meadows of baffling tabulate corals, brachiopod shells, or chlorophytes. These reefs mark an early phase of reef recovery after a prominent reef gap of 5-6 million years following the Ordovician/Silurian mass extinction events. The reefs feature a maximal diversity of calcifying cyanobacteria, corals and stromatoporoids, but low diversity of brachiopods, nautiloids and crinoids. Following the North American Stratigraphic Code, we define herein the Menier Formation, encompassing the lower two members of the existing Jupiter Formation.</ABSTRACT>

89202 <TITLE>Ecological controls on Devonian stromatoporoid-dominated and coral-dominated reef growth in the Mackenzie Basin, Northwest Territories, Canada.</TITLE>
89203 <SOURCE>Canadian Journal of Earth Sciences 48, 12: 1543-1560.</SOURCE>
89204 <ABSTRACT>The Horn Plateau Formation, composed of isolated reefs, is part of the Devonian strata that formed in the Mackenzie Basin in the Northwest Territories, Canada. The reefs stretch over a ~350 km northeast-southwest trend and are dominated by tabulate and rugose corals in the northeast, near exposed Canadian Shield rocks, and stromatoporoids further out in the basin. Detailed facies analyses of each reef type shows distinct differences in their biological makeup, energy regimes, and carbonate sedimentation rates. Geochemical analyses (stable isotopes and rare-earth elements) set against established paleogeography in the Mackenzie Basin reveal that the coral-dominated and stromatoporoid-dominated reefs grew under different ecological

conditions. Separations in the data imply that the coral-dominated reefs grew in waters that were relatively enriched in nutrients and the stromatoporoid-dominated reefs, further down the ramp, were in oligotrophic conditions. With no current established method to directly measure Paleozoic nutrient levels or to detect where they were sourced from, it is unclear why the coral-dominated reefs experienced higher nutrient levels. The paleogeography of the Mackenzie Basin could have affected the apparent stratification of nutrients on the carbonate ramp. Possible nutrient sources in the area are from coastal upwelling from the open ocean northwest of the ramp, or locally sourced nutrients from runoff on the adjacent exposed Canadian Shield rocks.</ABSTRACT>

89215 <TITLE>Discovery of a Mississippian Reef in Turkey: The Upper Visean Microbial-Sponge-Bryozoan-Coral Bioherm From Kongul Yayla (Taurides, S Turkey).</TITLE>

89216 <SOURCE>Turkish Journal of Earth Sciences 20, 2011: 1-?.</SOURCE>

89217 <ABSTRACT>For the first time, a Mississippian reef is described from Turkey. This microbial-sponge-bryozoan-coral bioherm has been discovered in the Central Taurides (South Turkey), at Kongul Yayla located between Hadim and Taskent. The bioherm contains a rich and diversified fauna: sponges and rugose corals are of particular interest. The bioherm shows four main facies reflecting distinct growth stages from the base to the top: (1) the basal bioclastic beds, (2) the core facies formed of framestone comprising rugose corals, lithistid sponges, fistuliporid bryozoans and microbial boundstone, (3) the crest facies with large colonies of cerioid rugose corals and chaetetid sponges, and (4) the bioclastic facies containing reworked material from the bioherm in lateral and overlying positions to it. The entire bioherm is topped by siltstones with thin bioclastic horizons, often slumped. Siphonodendron pauciradiale and Lithostrotion maccoyanum are the guide taxa for the RC7β biozone and indicate an upper Asbian age for the bioherm. The Kongul Yayla bioherm resembles most the Cracoean reefs from northern England. It confirms the position of this buildup type along the platform margins and edges in the Palaeotethyan realm as seen in the British Isles, Belgium, southern France, southern Spain and North Africa. Facies and the coral fauna argue for a European affinity of the Anatolian terrane.</ABSTRACT>

89228 <TITLE>Lower Triassic stromatolites in Luodian County, Guizhou Province, South China: evidence for the protracted devastation of the marine environments.</TITLE>

89229 <SOURCE>Geobiology 10, 1: 48-59.</SOURCE>

89230 <ABSTRACT>Stromatolites are one of the oldest and most intriguing organosedimentary deposits. In contrast to stromatolites of the Precambrian to Early Ordovician, Phanerozoic equivalents occurred

episodically under specific conditions. A group of previously undescribed stromatolites in composition occur in the Lower Triassic (Olenekian) at the Dajiang section in the Luodian region of Guizhou Province, South China. We described the textures of these stromatolites with the aim of determining the genetic mechanisms and revealing the nature of interactions between micro-organisms and marine environments. Mesoscopic features show that the stromatolites consist of several sets of stacked slices, and that they are embedded in alternating beds of fine and coarse microsphere packstones that include aggregates of microspheres, forming grapestones and lumps. Microscopically, the stromatolites consist of spar- and dolomite-infilled microspheres (average diameter, 100 μm), micrites, peloids, small-sized pyrite framboids (average diameter, 5.8 μm) and fenestrae. Micrite-dominant intercalations accentuate laminated textures at a mesoscopic level and are laterally continuous with micrite-rich parts in surrounding interstromatolites, indicating the simultaneous, widespread deposition of these layers. The microspheres and associated micrites were the products of in situ microbial activity, probably sulphate-reducing or anoxygenic phototrophic bacteria, which led to the formation of these unusual stromatolites. Even during a protracted period of harsh marine conditions, the micrite-rich carpets were deposited intermittently on the stromatolites and their surroundings under severely anoxic/sulphidic conditions. The presence of Early Triassic stromatolites and their subtle but important vertical variations in texture provide a record of temporal changes in marine conditions during geobiologically critical intervals.

89241 <TITLE>Roles of clone-clone interactions in building reef frameworks: principles and examples.</TITLE>

89242 <SOURCE>Facies 57: 375-394.</SOURCE>

89243 <ABSTRACT>In living and fossil reefs, rapid upward clone growth provides positive topographic relief, the skeletal framework provides rigidity. Clonal organisms have been the chief frame-builders during most of the Phanerozoic, large clone size, growth habit, growth form, and arrangement of these clones in the framework result from rapid growth rates. Dense skeletal packing enhances rigidity and results in live-live interactions between juxtaposed clones. These interactions are both heterospecific and conspecific, the former mostly involve spatial competition whereas the latter involve clone fusion, self-overgrowth, and fission. We describe three types of fusion: (a) inter-clone fusion of two or more clones, each from a separate propagule, (b) intra-clone fusion of parts of the same clone having its origin from a single propagule, it includes recovery from partial clone degradation and self-overgrowth, (c) quasifusion between a live bud/polyp/zoid and a dead part (stem, branch) of the same or a different clone, i.e., a livedead association.</ABSTRACT>

89254 <TITLE>The impact of the Mid-Pleistocene Transition on the composition of submerged reefs of the Maui Nui Complex, Hawaii.</TITLE>
89255 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 299, 3-4: 493-506.</SOURCE>
89256 <ABSTRACT>The submarine reef terraces (L1-L12) of the Maui Nui Complex (MNC-the islands of Lanai, Molokai, Maui and Kahoolawe) in Hawaii provide a unique opportunity to investigate the impact of climate and sea level change on coral reef growth by examining changes in reef development through the Mid-Pleistocene Transition (900-800 ka). We present an analysis of the biological and sedimentary composition of the reefs that builds directly on recently published chronological and morphological data. We define nine distinct limestone facies and place them in a spatial and stratigraphic context within 12 reef terraces using ROV and submersible observations. These include oolitic, two coral reef, two coralline algal nodule, algal crust, hemi-pelagic mud, bioclastic and peloidal mud facies. These facies characterise environments from high energy shallow water coral reef crests to low energy non-reefal deep-water settings. Combining the bottom observations and sedimentary facies data, we report a shift in the observed sedimentary facies across the submerged reefs of the MNC from dominant shallow coral reef facies on the deep reefs to coralline algae dominated exposed outcrop morphology on the shallower reefs. We argue that this shift is a reflection of the change in period and amplitude of glacioeustatic sea level cycles (41 kyr and 60-70 m to 100 kyr and 120 m) during the Mid-Pleistocene Transition (MPT, ~800 ka), coupled with a slowing in the subsidence rate of the complex. The growth of stratigraphically thick coral reef units on the deep Pre-MPT reefs was due to the rapid subsidence of the substrate and the shorter, smaller amplitude sea level cycles allowing re-occupation and coral growth on successive cycle low-stands. Longer, larger amplitude sea level cycles after the MPT combined with greater vertical stability at this time produced conditions conducive to deep-water coralline algae growth which veneered the shallower terraces. Additionally, we compare reef development both within the MNC, and between the MNC and Hawaii. Finally we suggest that climatic forcings such as sea-surface temperature and oceanographic currents may also have influenced the distribution of coral species within the sample suite, e.g., the disappearance of the Acropora genus from the Maui Nui Complex in the Middle Pleistocene.</ABSTRACT>

89267 <TITLE>Facies of Devonian fore reef limestones: a quantitative study (Iberg Reef, Harz Mts., Germany).</TITLE>
89268 <SOURCE>Palaeobiodiversity and Palaeoenvironments 93, 1 : 91-101.</SOURCE>
89269 <ABSTRACT>Facies in a 238-m-long core drilled through the fore reef of the Devonian (Givetian-Frasnian) Iberg Reef is largely characterised by detrital deposits. Fibrous, early marine cements are common. Stromatoporoids, corals, and crinoids are the dominant reef-building taxa. Brachiopods, cephalopods, and conodontophorids belong to the reef dwellers. Reef destroyers include gastropods and rare echinoids.

Quantitative analysis of abundance data allows for delineation of five facies including detritus-rich grainstones- rudstones, cement- and detritus-rich grainstones-rudstones, cement-rich rudstones, stromatoporoid rudstones, and crinoid grainstones. Time-series analysis indicates cyclic sedimentation that might have been related to mid-late Devonian third-order sea-level variations. However, the long-term (mid-Devonian to Early Carboniferous) development of the Iberg Reef including the post-reef seamount stage was presumably controlled by subsidence.</ABSTRACT>

89280 <TITLE>Pendant bioconstructions cemented by microbial carbonate in submerged marine caves (Holocene, SE Sicily).</TITLE>

89281 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 388: 166-180.</SOURCE>

89282 <ABSTRACT>Unusual pendant bioconstructions occur within two submerged caves in the Plemmirio Marine Protected Area, south of Syracuse (SE Sicily). These cm- to dm-sized bioconstructions project downward from the cave roofs. The main framework builders are serpulids belonging to the genera Protula, Semivermilia and Josephella. Encrusting bryozoans, corals, hydrozoans and sponges are subordinately present, whereas bivalves and brachiopods are overall rare. These faunal associations are characteristic of the studied caves, but only in some places they form small bioconstructions that are cemented by microbial carbonates made up by autochthonous, peloidal to clotted peloidal and aphanitic micrite. The autochthonous micrite stabilizes the pendant bioconstructions, herein referred to as biostalactites. The microbial carbonate reveals high contents of bacterial lipid biomarkers. Among the most abundant compounds are mono-O-alkyl glycerol ethers (MAGEs) and branched fatty acids (10-Me-C16:0; iso- and anteiso-C15:0 and -C17:0), interpreted as biomarkers of sulfate-reducing bacteria. Other compounds preserved in the autochthonous carbonates include lipids derived from marine zoo- and phytoplankton (brassicasterol, dinosterol and monounsaturated short-chain fatty acids), unspecified marine bacteria (saturated and monounsaturated short-chain fatty acids) and land plants (long-chain fatty acids, long-chain alcohols, stigmasterol, sitosterol and campesterol). The observed lipid biomarker signatures are remarkably similar to those of post-glacial reefal microbialites, where microbialite formation in cavities of the coral framework was also mediated by sulfate-reducing bacteria. In the submerged caves of Plemmirio Marine Protected Area, serpulid colonies apparently occur preferentially where freshwater is seeping through crevices in the limestone. The consequent nitrification is believed to favor serpulid aggregation and the growth of other skeletal (i.e., bryozoans and corals) and soft-bodied organisms (i.e., sponges and ascidiae). The resultant accumulation of biomass and its taphonomy provide niches for sulfate-reducing bacteria, which induce carbonate precipitation cementing and stabilizing the biostalactites. The finding of pendant, cemented bioconstructions in the Mazzere and Granchi caves of the Plemmirio Marine Protected Area reveals that sulfate-reducing bacteria are involved in microbialite formation in various cryptic environments. The formation of such peloidal to clotted peloidal microcrystalline carbonates in cryptic ecosystems is a significant factor for the stabilization of different kinds of bioconstructions, spanning from

- small biostalactites to large reefs.</ABSTRACT>

- 89293 <TITLE>Devono-carboniferous carbonate platform systems of the Netherlands.</TITLE>
- 89294 <SOURCE>Geologica Belgica 15, 4: 284-296.</SOURCE>
- 89295 <ABSTRACT>Large Palaeozoic carbonate build-ups, globally important for hydrocarbon exploitation, are generally not associated with the Netherlands or with the larger Southern North Sea region. The last ten years, information of new wells and seismic imaging have changed this perception. Recent seismic interpretations have indicated massive reef like carbonate platforms far below conventional petroleum exploration targets in the Netherlands. Some of the platforms are very sizeable and comparison with dimensions of Mississippian build-ups in the Caspian region or Devonian reefs of Canada can be made. New well information, released the last two years, dates the upper part of the platform as Mississippian. Based on seismic interpretation, some platforms most likely contain a Devonian core. UK petroleum exploration on the Mid North Sea High also provides new insights into Devonian carbonate build-ups. Due to the great depth of the Devono-Carboniferous strata in most areas, it is unclear if these carbonate platform reservoirs are a new petroleum exploration frontier or are situated below the economic basement. For many years the same palaeogeographic map could be used for North western Europe for the Devonian and Mississippian time interval. The new data requires a revised palaeogeography. The following summary provides an overview.</ABSTRACT>

- 89307 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 290, 1-4: 11-19.</SOURCE>
- 89308 <ABSTRACT>The PaleoReefs Database indicates that reef abundance increased profoundly during the Triassic period, from a pronounced low in the Early Triassic to a major peak in the Norian. This expansion is also evident when standardizing for sampling. Corresponding to the reef expansion is a relative increase of scleractinian corals as reef builders, whereas the contribution of hypercalcifying sponges and microbes decreased during the Triassic. The numerical expansion of corals is paralleled by a proportional increase of morphological features that are suggestive of photosymbiosis, such that the Norian reef boom might be explained by the spread of photosymbiosis in corals. The geographical expansion of reefs was far less pronounced especially concerning palaeolatitude. Late Triassic reef growth was limited to more or less the same latitudinal range as modern reefs. As oxygen isotope data and new modeling results indicate declining temperatures and CO₂ concentrations during the Late Triassic, the lack

of latitudinal expansion might be attributed to global cooling. Reef development during the Triassic can thus be explained by the evolutionary spread of photosymbiosis balancing the effects of climatic cooling.

89319 <TITLE>On the potential for ocean acidification to be a general cause of ancient reef crises.</TITLE>

89320 <SOURCE>Global Change Biology 17: 56-67.</SOURCE>

89321 <ABSTRACT>Anthropogenic rise in the carbon dioxide concentration in the atmosphere leads to global warming and acidification of the oceans. Ocean acidification (OA) is harmful to many organisms but especially to those that build massive skeletons of calcium carbonate, such as reef corals. Here, we test the recent suggestion that OA leads not only to declining calcification of reef corals and reduced growth rates of reefs but may also have been a trigger of ancient reef crises and mass extinctions in the sea. We analyse the fossil record of biogenic reefs and marine organisms to (1) assess the timing and intensity of ancient reef crises, (2) check which reef crises were concurrent with inferred pulses of carbon dioxide concentrations and (3) evaluate the correlation between reef crises and mass extinctions and their selectivity in terms of inferred physiological buffering. We conclude that four of five global metazoan reef crises in the last 500 Myr were probably at least partially governed by OA and rapid global warming. However, only two of the big five mass extinctions show geological evidence of OA.</ABSTRACT>

89332 <TITLE>Volcanism and reef development in the Devonian: A case study from the Lahn syncline, Rheinisches Schiefergebirge (Germany).</TITLE>

89333 <SOURCE>Gondwana Research 17: 264-280.</SOURCE>

89334 <ABSTRACT>New data from the Rheinisches Schiefergebirge in Germany offer insights into a complex marine basinal facies setting on the southern shelf area of the Old Red Continent. This interdisciplinary approach has the aim of providing a reconstruction of depositional and palaeoecological conditions of volcanic island induced reef growth during the Middle Devonian time. Devonian volcanic activity culminated in a Givetian-Frasnian phase producing mainly alkali-basaltic to basaltic melts. Some volcanic buildups reached sea level and gave rise to the development of reefs during times of reduced volcanic activity. Reef communities in the Lahn syncline were dominated by corals and stromatoporoids. In terms of conodont stratigraphy they began to flourish during the Middle varcus-subzone in the Givetian and lasted until the Late falsiovalis-subzone in the Frasnian. A facies model is presented for the entire area that clarifies the association of volcanism and reef development.</ABSTRACT>

89346 <SOURCE>Geological Society, London, Special Publication 376: 343-366.</SOURCE>
89347 <ABSTRACT>As important components of extinct as well as modern reefs, the measurement of changes in the composition of reef biota is crucial in order to evaluate the influence of extrinsic factors on the marine communities. The dramatic abiotic changes in the eastern and northern Pangea was mirrored by a gradual transition from a photozoan to a heterozoan association and the appearance of cool- (temperate-) water carbonates both in reef and carbonate ramp environments. Analyses of large skeletal and microbiotic components as well as microfacies succession were used for detailed explanation of reef structure, especially for lesser-known heterozoan skeletal mounds. The youngest skeletal mounds are recognized in the Roadian. The stable isotope data demonstrated a negative oxygen shift between latest Sakmarian and late early Artinskian coinciding with the end of P2 glaciation. The multiplicative nature of the event included the series of successive changes of extrinsic factors such as ice melting in interglacial episodes, eustatic ocean level rise, change of oceanic circulation and decrease of water temperature. The late Artinskian and subsequent Kungurian climatic impacts in the Northern Hemisphere were irreversible for the photozoan biota and prevented its further development. Roadian (Guadalupian) bryonoderm extended skeletal mounds developed in rather warm-water environments.</ABSTRACT>

89359 <SOURCE>Facies 56, 1: 1-11.</SOURCE>
89360 <ABSTRACT>The bleaching event of 1998 caused widespread mortality on coral reefs in the Maldives. Nearly 10 years after the coral mass mortality, the state of Maldivian reefs was evaluated paying specific attention to three ecological stages, linked to the 3D structure of the coral community: young (high living hard coral cover), mature (a balance between living coral cover and loose sediment), and regressive (high amount of rubble and sand). The relative importance of three biogeomorphological descriptors (living hard corals; rubble and sand; coralline algae on rock) in the reef flat (2-7 m depth) and in the slope (7-18 m) of three reefsapes related to wave exposure was assessed. The role of wave energy in shaping ecological stages is different in the reef flat (early stages are found in low energy conditions) and in the slope (early stages are associated with high energy sites).</ABSTRACT>

89397 <TITLE>Platy coral patch reefs from eastern Panthalassa (Nevada, USA): unique reef construction in the Late Triassic.</TITLE>
89398 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 313-314: 41-58.</SOURCE>
89399 <ABSTRACT>Upper Triassic (Lower Norian) reefal buildups near Mina, Nevada, represent some of the earliest scleractinian coral reefs from eastern Panthalassa. The small patch reefs (~ 20-40 m high and ~ 50-150 m wide, obvious metre-scale elevation above the surrounding sediments) are from the Luning Allochthon and grew on an inner to middle ramp or in a deep lagoon. The Mina patch reefs were constructed by several different coral ecomorpho- types (platy, tabular, domal/massive, and branching corals) interpreted to have had zooxanthellate symbionts, and record subtle coral zonation within the reefs. Based on modern coral ecomorphotypes, platy to tabular corals at Mina grew in the lower euphotic zone (stressed by low light conditions), and the massive or domal corals inhabited shallower water (possibly above fair weather wave base) and were stressed by wave energy. Unlike most other Late Triassic reef ecosystems where phaceloid branching corals or calcareous sponges constitute the principal bioconstructors, the platy to tabular corals were the primary builders in the Mina patch reefs. The Mina reefs are also unique because cryptic and cavernous internal environments, epibionts, cryptobionts, and thick microbial crusts are rare or absent. The combination of platy coral dominance with the lack

of epibionts/cryptobionts/microbial crusts suggests that the Norian reefs from Mina, Nevada represent a unique form of scleractinian reef construction from the Late Triassic.</ABSTRACT>

89410 <TITLE>Depth transect of an Upper Triassic (Rhaetian) reef from Gosau, Austria: Microfacies and community ecology.</TITLE>

89411 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 376: 1-21.</SOURCE>

89412 <ABSTRACT>In the Late Triassic (~235-201.3 Ma) scleractinian corals and hypercalcified sponges built large, diverse reef ecosystems, the most famous of which are the Dachstein reefs. This study presents a depth transect along an Upper Triassic (lower Rhaetian) Dachstein reef from the Gosausee margin of the Dachsteingebirge (Gosau, Austria). The Gosausee microbial-sponge-coral reef is a complete barrier reef with an almost continuous fore reef to lagoon transect preserved (a very rare occurrence for the Triassic), and thus provides a window into depth zonation of Dachstein-type reef facies and biotic succession. The Gosausee reef facies exhibit strong depth control and five classic reef facies or zones are identified: the fore reef, reef front, reef crest, back reef, and lagoon facies. Thin, rare microbial fabrics and a high abundance of fine-grained, mud-rich skeletal wackestones (transported reef debris) characterize the deepest fore reef. As the reef shallows, muddy sediments decrease in abundance and are replaced by microbial fabrics, corals, and cements. Abundant sponges, microbial crusts, and thick, marine cements typify the reef crest, whereas microbialite-coated phaceloid corals are dominant in the back reef facies. Heavily cemented oncoids or microbial-sponge bindstones are characteristic of the lagoon. Based on their compositional and biotic similarities, the Gosausee reef was likely part of the same barrier reef systems as the source reef for the Gosaukamm reef breccia (one of the classic Norian-Rhaetian Dachstein reefs). The reef zones of the Gosausee margin can be used to interpret the depth or reef zone of less well preserved reef fragments, can inform models of community ecology and niche utilization in the Late Triassic, and highlight the need for additional research into the environmental factors that controlled biotic distribution in Upper Triassic reefs.</ABSTRACT>

89423 <TITLE>Microbial framework in Upper Triassic (Carnian) patch reefs from Williston Lake, British Columbia, Canada.</TITLE>

89424 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 297, 3-4: 609-620.</SOURCE>

89425 <ABSTRACT>The Upper Triassic (Carnian) patch reefs from Pardonet Hill, British Columbia, Canada are the only known Upper Triassic reefal buildups from the craton margin of northwestern Pangaea. These buildups

occur within the lower Baldonne Formation and are characterized by a moderately diverse assemblage of corals, spongiomorphs, crinoids, echinoderms, bivalves, gastropods, brachiopods, and microbialites. Despite the evidence that these buildups had a rigid structure (e.g. brecciation and hardgrounds) and relief above the seafloor (visible in outcrop), the exact nature and extent of the framework has previously been undetermined. This study focuses on the microfacies within these patch reefs and highlights the importance of microbialites in the framework of these diminutive buildups (~100m³ to 500m³). * The Pardonet Hill patch reefs were mapped in outcrop to determine their structure, geometry, and the importance of large metazoan framework builders. Samples of the reefal horizons and surrounding strata were evaluated utilizing point count analyses of organisms, cements, lithic grains, and microbial textures in thin section. Quantitative analysis of the microfacies in concert with traditional descriptions of reef construction and reef classification allow a more thorough understanding of organism abundance and reef structure. * Despite the presence of corals and spongiomorphs throughout the outcrop, they very rarely form a true, intergrown framework, except at the base of Patch Reef B. Instead, cemented microbialites form a rigid framework in the core of some patch reefs. Detailed examination of the microfacies and reef construction demonstrates the importance of non-skeletal framework builders in the structural fabric of these small buildups. Pardonet Hill Patch Reef B is the first true reef with a microbial framework documented from the Upper Triassic of North America. This microbial-coral framework bears a striking similarity to some Triassic and Upper Jurassic coral-microbial reefs from the Tethys, although the depositional environment of the Pardonet Hill patch reefs is likely shallower and more energetic than the Tethyan reefs.

89436 <TITLE>The shifting biogeography of reef corals during the Oxfordian (Late Jurassic). A climatic control?</TITLE>

89437 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 365-366: 136-153.</SOURCE>

89438 <ABSTRACT>Until recently, the Jurassic was thought to have been a period characterised by a predominantly warm and equable climate. During the Oxfordian (a time span of six million years in the Late Jurassic) the distribution of tropical coral reefs was limited to about 35°N and near to 25°S. However, in Middle Oxfordian time, coral reefs were abundant only at higher latitudes and almost entirely missing near the equator. During that time the area of maximum reef development had shifted poleward to a belt lying between 20°N and 35°N, leaving hardly any coral formations at the lower inner-tropical latitudes. After demise towards the end of Middle Oxfordian time, the low-latitude reefs recovered during the Late Oxfordian, accompanied by a southward migration of reef corals in the northern hemisphere. As suggested by stable isotope and palynological data, the faunal migration can be correlated with a significant rise in seawater temperature during the Middle Oxfordian.</ABSTRACT>

89449 <TITLE>Reef recovery following the Frasnian-Famennian (Late Devonian) mass extinction: evidence from the Dugway Range, West-Central Utah.
</TITLE>
89450 <SOURCE>Palaios 26: 607-622.</SOURCE>
89451 <ABSTRACT>The temporally extensive late Middle through Late Devonian biotic crisis involved at least three distinct peaks of elevated extinction intensity during an interval spanning ,25 myr and resulted in the preferential elimination of certain shallow-marine, warm-water taxa, especially members of reef communities. By the end of the second peak, delimited by the Frasnian-Famennian (F-F) boundary, the stromatoporoids, members of the dominant constructor guild in mid-Paleozoic reefal ecosystems, had ceased building reefs in most parts of the world. The northern Dugway Range in west-central Utah, United States, however, represents one of the few locations globally where stromatoporoids continued reef building into the Famennian. Two measured sections there, which are constrained biostratigraphically using conodonts, indicate that the biohermal sequences occur within the middle *Palmatolepis crepida* biozone and are early Famennian in age. The post-F-F extinction Dugway reefal faunas are depauperate and dominated by labechiid and stylostromid stromatoporoids, as is characteristic of other early Famennian reefs. In this region, evidence for reefal development is episodic, with stromatoporoid-bearing units interbedded with peloidal and coated-grain carbonate units lacking evidence of reef construction. The stromatoporoid survivors, although fairly minor constituents of Frasnian reef communities, belong to long-ranging clades and may represent so called extinction-resistant taxa that flourished, albeit locally in Laurentia, following the F-F mass extinction.</ABSTRACT>

89462 <TITLE>Mesophotic coral buildups in a prodelta setting (Late Eocene, southern Pyrenees, Spain): a mixed carbonate-siliciclastic system.
</TITLE>
89463 <SOURCE>Sedimentology 59: 766-794.</SOURCE>
89464 <ABSTRACT>Lower Priabonian coral bioherms and biostromes, encased in prodelta marls/clays, occur in the Ai´nsa-Jaca piggyback basin, in the South Central Pyrenean zone. Detailed mapping of lithofacies and bounding surfaces onto photomosaics reveals the architecture of coral buildups. Coral lithosomes occur either isolated or amalgamated in larger buildups. Isolated lithosomes are 1 to 8m thick and a few hundred metres wide; clay content within coral colonies is significant. Stacked bioherms form low-relief buildups, commonly 20 to 30m thick, locally up to 50m. These bioherms are progressively younger to the west, following progradation of the deltaic complex. The lowermost skeletal-rich beds consist of bryozoan floatstone with wackestone to packstone matrix, in which planktonic foraminifera are abundant and light-related organisms absent. Basal coral biostromes, and the base of many bioherms, consist of platy-coral colonies ‘floating’ in a fine-grained matrix rich in branches of red algae. Corals with

domal or massive shape, locally mixed with branching corals and phaceloid coral colonies, dominate buildup cores. These corals are surrounded by matrix and lack organic framework. The matrix consists of wackestone to packstone, locally floatstone, with conspicuous red algal and coral fragments, along with bryozoans, planktonic and benthonic foraminifera and locally sponges. Coral rudstone and skeletal packstone, with wackestone to packstone matrix, also occur as wedges abutting the buildup margins. Integrative analysis of rock textures, skeletal components, buildup anatomy and facies architecture clearly reveal that these coral buildups developed in a prodelta setting where shifting of delta lobes or rainfall cycles episodically resulted in water transparency that allowed zooxanthellate coral growth. The bathymetric position of the buildups has been constrained from the light-dependent communities and lithofacies distribution within the buildups. The process-product analysis used here reinforces the hypothesis that zooxanthellate corals thrived in mesophotic conditions at least during the Late Eocene and until the Late Miocene. Comparative analysis with some selected Upper Eocene coral buildups of the north Mediterranean area show similarities in facies, components and textures, and suggest that they also grew in relatively low light (mesophotic) and low hydrodynamic conditions. </ABSTRACT>

89475 <TITLE>Environmental reconstruction of a late Burdigalian (Miocene) patch reef in deltaic deposits (East Kalimantan, Indonesia).</TITLE>

89476 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 374: 110-122.</SOURCE>

89477 <ABSTRACT>Most studies of Cenozoic shallow-water, mixed carbonate-siliciclastic depositional systems have focused on their sedimentology. To date, however, comprehensive analyses of biotas and biofacies of Indo-West Pacific reefs that developed in mixed carbonate-siliciclastic systems are lacking. This study describes the palaeoenvironment and biodiversity of a late Burdigalian patch reef that developed in a mixed carbonate-siliciclastic depositional system. The studied exposure is located at the northeast margin of the Kutai Basin near Bontang (Indonesia), and is approximately 80m wide and 25m thick. Multi-taxon analysis of the most abundant fossil groups, including larger benthic foraminifera, corals, coralline algae, and bryozoans, aims to provide a model for environmental interpretation that will allow comparison with similar deposits of Indo-West Pacific region. Based on fossil content and lithology, five different facies types have been distinguished: foraminiferal packstone (FP), bioclastic packstone with foralgal communities (BP), thin-platy coral sheetstone (CS), platy-tabular coral platestone (CP), and shales (S). Among larger benthic foraminifera, smaller and more robust forms dominate in the FP and BP facies, while larger and flatter forms are the most abundant in the CS and CP facies. Thin-platy corals are dominant in the CS facies and gradually change into thicker platy-tabular forms in the CP facies. Assemblages and growth forms of coralline algae show no major differences between the facies types and are dominated by melobesoids and sporeolithon. The majority of bryozoan species are encrusting and were found only in the CS facies. Light-dependent organisms occurring in the reef indicate low light conditions typical for mesophotic reefs. The relatively small size of this reef complex and quite distinct

vertical changes in the facies types, combined with the high siliciclastic content in most of the units, points to strong terrigenous input affecting water transparency as the main factor controlling the reef growth.</ABSTRACT>

89488 <TITLE>Carboniferous buildups in the Donets Basin (Ukraine).</TITLE>

89489 <SOURCE>Geologica Belgica 15, 4: 340-349.</SOURCE>

89490 <ABSTRACT>The Carboniferous (Mississippian and Pennsylvanian) of the Donets Basin contains bioherms and biostromes in several stratigraphic levels. The study of buildups of this region and their comparison with other areas allows to suggest that the composition of reef-building organisms changed during the Carboniferous. Up to the late Visean, they were formed on a shallow water carbonate platform, whereas younger bioconstructions are restricted to distinctive limestone horizons of cyclothems. Visean shallow-marine bioconstructions are represented by Siphonodendron-biostromes which are typical for the Late Visean of many areas of the Paleothetys. In the unstable conditions of the paralic basin with frequent environmental changes bioconstructions formed during transgressive phases. The late Serpukhovian buildups were complex coral-chaetetid biostromes and bioherms. In Bashkirian times appeared chaetetid and coral-chaetetid biostromes as well as algal bioherms. In the early Moscovian coral and coral-chaetetid biostromes were the most common. During the middle Moscovian dominated bioherms probably of microbial origin, and at the end of Moscovian time chaetetid biostromes were typical. At the earliest Gzhelian time algae-sponge bioherms appeared in the Donets Basin.</ABSTRACT>

89501 <TITLE>Microbial carbonates and corals on the marginal French Jura platform (Late Oxfordian, Molinges section).</TITLE>

89502 <SOURCE>Facies 57, 3: 469-492.</SOURCE>

89503 <ABSTRACT>Molinges was located on an Upper Jurassic ramp system of low-energy regime that developed at the southern margin of the French Jura platform. The sedimentary succession is characterized by the transition from a mixed siliciclastic-carbonate to a carbonate depositional setting that occurred during a long-term shallowing-upward trend. The disappearance of siliciclastics is explained by a climatic change, from humid and cold to drier and warmer conditions, previously identified in Late Oxfordian adjacent basins. The base of the section shows marl-limestone alternations of outer ramp. In its middle part, the section displays oncolitic marls, coral-microbialite beds and oncolitic limestones that deposited in a mid ramp position. Finally, the upper section part is made of oolitic limestones of inner ramp. In outer- to mid-ramp settings submitted to terrigenous inputs, the

stacking pattern of deposits and facies evolution allow the identification of elementary, small-, medium-, and large-scale sequences. Small amplitudes of sea-level variations probably controlled rapid shifts of facies belts and reef window occurrences. In small-scale sequences, the coral beds developed during periods of sea-level rise. The decreasing rate of sea-level rise is marked by the downramp shift of the oncolitic limestone belt that led to the demise of coral-microbialite beds. These bioconstructions are mainly represented by thin biostromes in which corals never reach great sizes. The coral assemblages mainly include the genera *Enallhelia*, *Dimorpharaea*, *Thamnasteria*, and some solitary forms (*Montlivaltia* and *Epistreptophyllum*). They suggest relatively low-mesotrophic conditions in marine waters during the edification of the primary framework. Relatively cold water temperatures and periods of more elevated nutrient contents are probably responsible of the reduced coral development and the formation of a large amount of microbialites.

89527 <TITLE>Post-tectonic limitations on Early Devonian (Emsian) reef development in the Gobi-Altai region, Mongolia.</TITLE>

89528 <SOURCE>Lethaia 45, 1: 46-61.</SOURCE>

89529 <ABSTRACT>This study investigates a Lower Devonian (Emsian) carbonate sequence from the Chuluun Formation where it is exposed in the Gobi-Altai region of southern Mongolia. Quantification of abundance patterns across guild, morphotype and general taxonomic levels was based on stratigraphical and thin-section analyses. Comparison with other Emsian carbonate platforms allowed the factors that influenced community development in the wake of a tectonic perturbation to be determined. Our evidence reveals that potential reef-building biotas preserved in the Chuluun Formation experienced rapid colonization of a newly submerged carbonate platform following an episode of tectonic uplift and the development of a coastal alluvial fan. Although critical reef-building organisms were present, colonial corals and stromatoporoids exhibited limited vertical growth and showed no

significant lateral expansion of individuals or biotic assemblages. Nor did those taxa experience significant increases in abundance, density, or size. We conclude that incomplete succession and the lack of reef development occurred most likely because of an unsuitable substrate, limited accommodation space and isolation that reduced colonization potential.

89540 <TITLE>Early (Series 2) Cambrian archaeocyathan reefs of southern Labrador as a locus for skeletal carbonate production.</TITLE>
89541 <SOURCE>Lethaia 45, 3: 401-410.</SOURCE>
89542 <ABSTRACT>Archaeocyathan reefs, the first reefs produced by animals, are prominent, global features of early Cambrian successions. However, microbialites - the dominant reef components of the Proterozoic - were still abundant in most archaeocyathan reefs. Although such reefs were a locus for carbonate production, it is unclear how much carbonate was produced skeletally. This analysis of well-known early Cambrian archaeocyathan patch reefs of the Forsteu Formation, southern Labrador, demonstrates that skeletal carbonate was abundantly produced in these archaeocyathan reefs, although only about half was produced by archaeocyathans. Trilobites, echinoderms and brachiopods contributed substantially to the total carbonate budget, particularly in grainstone facies flanking the reefs. Through point count analysis of samples collected from the reef core and flanking grainstones, it can be demonstrated that skeletal material was most abundant in grainstone facies, where animals such as trilobites and echinoderms contributed significantly to carbonate production. In contrast, microbial fabrics were more abundant than skeletal fabrics in the reef core, although archaeocyathan material was more abundant than other skeletal debris. Similar to modern reefs, these reefs created a variety of habitats that allowed for the proliferation of skeletal organisms living on and around the reef, thereby promoting skeletal carbonate production through ecosystem engineering.</ABSTRACT>

- 89568 <ABSTRACT>Land-use changes and associated deteriorations in water quality are cited as major drivers of marine ecosystem change, and can modify community abundance and diversity on coral reefs. This study uses palaeoecological data derived from a mid-Holocene age coral reef in the wet Tropics region of Australia's Great Barrier Reef to develop a record of coral community composition and diversity, from a period that significantly pre-dates European settlement in the region. Major changes in catchment sediment and nutrient yields since European settlement have been documented, and thus the data presented provides a baseline against which to compare contemporary ecological datasets. Natural variations in coral assemblage composition, as preserved in core records, clearly occurred in this mid-Holocene reef and were associated with the reef shallowing to sea level as it accreted vertically. Comparisons between modern and mid-Holocene coral community data from equivalent water depths did not reveal marked shifts in coral community composition and diversity, suggesting the long-term persistence of a resilient coral assemblage over these time periods.</ABSTRACT>

- 89580 <SOURCE>Geological Journal 47, 5: 462-476.</SOURCE>
- 89581 <ABSTRACT>The excellent exposure and preservation of a fringing reef located at Tiouinine, near Khenifra (Central Moroccan Meseta) is a unique case in the Mississippian which allows us to distinguish different facies belts of a classical coral framework reef. The reefal facies rest on thin basal siliciclastic rocks which rest unconformably on Ordovician sandstones. There is a complete zonation from tidal deposits of the inner shelf to reefal talus of the mid to outer shelf. Tidal deposits occur in a narrow band and are composed of sandy packstones. There is a transition to reef flat deposits composed of skeletal packstone-grainstone with a patchy distribution of coral colonies. There is also a transitional change to core reef facies that are composed of fasciculate and massive corals reinforced by dasyclad algal masses around the corals and microbial micropeloidal mudstone to wackestone coating the corals and algae. The spaces between the corals and algal masses are infilled by crinoidal and coral grainstone. The dominant building organisms are rugose corals of the genera Siphonodendron, Lithostrotion, Diphyphyllum and Tizraia, as well as contributions from the tabulate genera Michelinia, Multithecopora and Syringopora. The proximal reef talus is represented by skeletal packstone and rudstone containing highly diverse bioclasts, with corals, crinoids, foraminifers, gastropods and bivalves, as well as large fragments of reworked coral colonies and some coral colonies in growth position. These beds show erosive surfaces and amalgamation of

beds. A somewhat more distal reef talus is represented by well-bedded marly limestones containing mainly crinoids and branches of fasciculate corals. The existence of a well-preserved coral reef in the late Visean contradicts the concept that rugose and tabulate corals did not build reefs after the Late Devonian extinction.</ABSTRACT>

89592 <TITLE>Sea-level rise and coral-reef development of Northwestern Luzon since 9.9 ka.</TITLE>

89593 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 292, 3-4: 465-473.</SOURCE>

89594 <ABSTRACT>Coral reef growth and relative sea-level record for the early mid-Holocene are established from three boreholes drilled on a raised Holocene reef at Currimao, northwestern Luzon, Philippines. Age control is provided by 230Th dates of 13 corals mostly in living position. The cores cover a depth interval from 3.8m above to 26.7m below present mean sea level (MSL) and consist of four lithofacies including (1) reef facies, (2) bioclastic facies, (3) clayey facies and (4) tuffaceous facies. The ages of dated corals vary from 6588 ± 27 ya at 1.4m below MSL to 9855 ± 42 ya at 22m below MSL. Results of this study indicate that the reef started growing about 9.9 ka when the minimum sea level, relative to the western Luzon coast, was about 27m below MSL after tectonic correction. During 9.2-8.2 ka, reef accretion rate was as high as 10-13m/ky. Coral reef developed to near paleo-sea level at about 6862 ± 28 ya and emerged due to tectonic uplift. The sea-level curve of Currimao is generally similar to that of the western Australia coast but at least 8-11m higher than that of Tahiti from 10 to 8.5 ka.</ABSTRACT>

89605 <TITLE>Genesis and internal architecture of the Middle to Upper Devonian Gwirat Al Hyssan reef-mound (western Sahara).</TITLE>

89606 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 304: 184-193.</SOURCE>

89607 <ABSTRACT>On the southern flanks of the Tindouf Basin (western Sahara) reefal complexes of various sizes were developed, mostly of Givetian age but possibly reaching into the early Frasnian. Surrounding sedimentary rocks were dominantly sandstones, siltstones and marls. The larger reef complexes in the northeastern part of western Sahara show three reef cycles within the Givetian and lowermost Frasnian, interrupted by marly sedimentation. Farther to the west, more isolated reef structures in open shelf settings occur often showing smaller dimensions. The present study focuses on one of these western reefal build-ups. Besides large-scale reefs dominated by stromatoporoids (NE), several smaller bioherms have been investigated, such as the Gwirat Al

Hyssan reef mound near Smara. Initial reef growth was of late Givetian age as indicated by corals (e.g. *Heliolites*). The main reef builders were the corals *Alveolites*, *Thamnopora*, *Aulopora*, *Frechastraea*, *Phillipsastrea*, and, to a lesser degree, *Heliolites*, *Scoliopora*, and *Roemerolites*. *Stromatoporoids* also contributed, but were less frequent. *Chaetetids* (e.g. *Rhaphidopora*) acted as pioneer stabilizers on bare sediment surfaces. Preservation in life position was frequently observed in both groups of organisms. Crinoids are not rare, but only present as debris. In distinct areas of the reef (depressions) concentrations of brachiopods and small solitary corals occur. The reef-mound has a present elevation of 17 m and measures about 370 m in diameter. Vertical as well as horizontal zonation could be recognized in detail. The initial reef growth started on a submarine shoal of siliciclastic sediments, containing various trace fossils and sedimentary structures such as cross-bedding and wave ripples, interference ripples suggest generation in very shallow water. The initial reef-building organisms were encrusting chaetetids, followed by platy *Frechastraea* colonies, *thamnoporids* were also present. The overlying reef limestones consist of different corals and, to a minor degree, *stromatoporoids*. The latter are sparsely distributed vertically as well as horizontally, depending on their position within the reef. Growth forms are more robust (bulbous) towards higher hydrodynamic conditions at the southern reef front. Reef growth is interrupted by debris limestones of *thamnoporid* and *crinoid* bioclasts, intercalated with detrital platy *stromatoporoids*. Generally, the debris was not transported over long distances, as demonstrated by the presence of relatively large fragments. This debris phase (early Frasnian) is overlain by the last documented stage in reef development represented by medium- to thin-bedded coral-rich limestones. The onset of the carbonate production of the Gwirat Al Hyssan reef-mound is maybe related to the global transgressive Givetian - Frasnian Boundary Event.

89618 <TITLE>Microbial mounds prior to the Frasnian-Famennian mass extinctions, Hantang, Guilin, South China.</TITLE>

89619 <SOURCE>Sedimentology 57: 1615-1639.</SOURCE>

89620 <ABSTRACT>Late Frasnian mounds of the Yunghsien Formation, Guilin, South China, developed as part of the Guilin platform, mostly in reef-flat and platform margin settings. Microbial mounds in platform margin settings at Hantang, about 10 km west of Guilin, contain Frasnian biota, such as *Stachyodes* and *Kuangxiastraea* and, thus, occur below the Frasnian-Famennian mass extinction boundary. Platform margin facies were dominated by microbes, algae and *receptaculitids*. Massive corals and *stromatoporoids* are not common and rarely show reef-building functions as they did in Givetian time. The margin mounds are composed of brachiopod-*receptaculitid* cementstone, and a variety of boundstones that contain *Rothpletzella*, *Renalcis*, *thrombolite* and *stromatolite*. Other microbial communities include *Girvanella*, *Izhella*, *Ortonella* and *wetheredella*. *solenoporoid* algae are abundant locally. Zebra structures and *neptunian* dykes are well-developed at some intervals. Pervasive early cementation played an important role in lithification of the microbial boundstones and rudstones. Frasnian reefs of many regions of the world were constructed by *stromatoporoids* and corals, although a shift to calcimicrobe-dominated frameworks occurred before the

Famennian. However, the exact ages of many Frasnian margin outcrops are poorly constrained owing to difficulties dating shallow carbonate facies. The Hantang mounds represent a microbe-dominated reef-building community with rare skeletal reef builders, consistent with major Late Devonian changes in reef composition, diversity and guild structure occurring before the end of the Frasnian. A similar transition occurred in the Canning Basin of western Australia, but coeval successions in North America, western Europe and the northern Urals are either less well-known or represent different bathymetric settings. The transition in reef-building style below the Frasnian-Famennian boundary is documented here in the two best exposed successions on two continents, which may have been global. Set in the larger context of Late Devonian and Mississippian microbial reef-building, the Hantang mounds help to demonstrate that controls on microbial reef communities differed from those on larger skeletal reef biota. Calcimicrobes replaced stromatoporoids as major reef builders before the Frasnian-Famennian extinction event, and increasing stromatoporoid diversity towards the end of the Famennian did not result in a resurgence of skeletal reef frameworks. Calcimicrobes dominated margin facies through the Famennian, but declined near the Devonian-Carboniferous boundary. Stromatolite and thrombolite facies, which occurred behind the mound margin at Hantang, rose to dominate Mississippian shallow-water reef frameworks with only a minor resurgence of the important Frasnian calcimicrobe *Renalcis* in the Visean when well skeletonized organisms (corals) also became volumetrically significant frame builders again. 89644 <TITLE>Comment on " Reef recovery following the Frasnian-Famennian (Late Devonian) mass extinction: evidence from the Dugway Range, West-Central Utah" published in Palaios by J. R. Morrow, P. J. Harries and J. G. Krivanek.</TITLE>

89645 <SOURCE>Subcommission on Devonian Stratigraphy Newsletter 28: 15-24;

Arlington, Texas.</SOURCE>

89646 <ABSTRACT>Morrow et al. (2011) reported the first occurrence of Famennian stromatoporoids in the United States... Despite some errors in this paper in documenting a low Famennian occurrence, we herein confirm that it is datable as Middle crepida Zone... This otherwise important contribution suffers from four circumstances: (1) The senior author, Jared Morrow, who was knowledgeable in the local geology of the Dugway Range and in the Devonian of the western United States, could not have been involved in the final assembly of the published paper... (2) Unfortunately, the authors did not include stromatoporoid generic geologic range information from three extant publications by Stearn et al. (1999), Nestor & Stock (2001), and Stock (2005)... (3) The M.S. thesis by Krivanek (2006), which bears nearly the same title as Morrow et al. (2011) and is undoubtedly its source, was not referenced. (4) Morrow et al. (2011) was not peer reviewed by any scientists with extensive knowledge of stromatoporoids, conodonts, complex local geology, or geology of the western United States... Following are some of the many errors that detract from this important contribution... Problems arise with the presentation of Morrow et al. (2011) Figure 12, a compilation of the geologic ranges of Paleozoic stromatoporoid genera, and interpretations based on that figure. Here is presented an updated genus range chart (Fig. 1), and commentary on their interpretations... [abridged]</ABSTRACT>

89657 <TITLE>Shallow water mud-mounds of the Early Devonian Buchan Group, East Gippsland, Australia.</TITLE>

89658 <SOURCE>Sedimentary Geology 281: 208-221.</SOURCE>

89659 <ABSTRACT>The Lower Devonian Rocky Camp Member of the Murrindal Limestone, Buchan Group of southeastern Australia consists of a series of carbonate mud-mounds and smaller lagoonal bioherms. The Rocky Camp mound is the best exposed of the mud-mounds and has many characteristics in common with Waulsortian (Carboniferous) mounds. Detailed paleoecological and sedimentological studies indicate that the mound initially accumulated in the photic zone, in contrast to most of the previously recorded mud-mounds. Five facies are present in the mud-mound: a Dasycladacean Wackestone Facies at the base of the mound represents a moderate energy, shallow water bank environment within the photic zone. A Crinoidal Wackestone Facies was deposited in a laterally equivalent foreslope setting. A Poriferan-Crinoidal Mudstone Facies developed in a quiet, deeper water, lee-side mound setting associated with a minor relative sea-level rise. A Stromatoporoid-Coralline Packstone Facies in the upper part of the mound deposited in a high-energy, fair-weather wave base, mound-front environment. The crest of the mound is represented by a Crinoidal-Receptaculitid Packstone Facies indicative of a moderate-energy mound-top environment in the photic zone, sheltered by the mound-front stromatoporoid-coral communities. A mound flank facies is present on the southern side of the mound and this consists of high-energy crinoidal grainstones. Mud-mound deposition was terminated by a transgression that deposited dark gray, fossil-poor marl of the overlying Taravale Formation. The Rocky Camp mound appears to have originated in shallow water photic zone conditions and grew into a high-energy environment, with the mound being eventually colonized by corals and stromatoporoids. The indications of a high-energy environment during later mound growth

- (growth form of colonial metazoans and grainstones of the flanking facies) suggest that the micrite in the mound was autochthonous and implies the presence of an energy damping mechanism (probably biological) at the mound surface.</ABSTRACT>

- 89685 <ABSTRACT>Upper Thanetian microbialite-coral mounds from the Adriatic Carbonate Platform (SW Slovenia) are described herein for the first time, representing an important case study of extensively microbially-cemented boundstones in the Early Paleogene. The mounds are constructed primarily by microbialites associated to small-sized coral colonies, forming metric bioconstructions in a mid-ramp setting. * Detailed macroscopic and microscopic studies show that microbes are the major framework builders, playing a prominent role in the stabilization and growth of the mounds, with corals being the second most important component. Microbial carbonates represent up to 70% of the mounds, forming centimetric-thick crusts alternating with coral colonies. The microbial nature of the crusts is demonstrated by their growth form and internal microfabrics, showing accretionary, binding, and encrusting growth fabrics, often with gravity-defying geometries. Thin sections and polished slabs reveal a broad range of mesofabrics, with dense, structureless micrite (leiolite), laminated crusts (stromatolites), and clotted micritic masses (thrombolites). A first layer of micro-encrusters, including leiolites and thrombolites, occurs in cryptic habitats, whereas discontinuous stromatolites encrust the upper surface of corals. A second encrustation, the major mound construction phase, follows and is dominated by thrombolites, encrusting corals and other micro-encrusters. This sequence represents the basic constructional unit horizontally and vertically interlocked, in an irregular pattern, to form the mounds. The processes, which favored the deposition of these microbial carbonates, were mainly related to in situ precipitation, with minor evidences for grain agglutination and trapping processes. * Scleractinian corals comprise moderately diversified community of small (centimetric) colonial, massive, platy encrusting, and branching forms. Coral colonies are distributed

uniformly throughout the mounds without developing any ecological zonation. These features indicate that coral development remained at the pioneer stage throughout the mound growth. * The spatial relationships between corals and microbialites, as well as the characteristics of microbial crusts and coral colonies, indicate a strong ecological competition between corals and microbes. A model for the evolution of the trophic structures during the mound growth is proposed, with changes in the paleoecology of the main bioconstructors triggered by frequent environmental perturbations. Turbidity and nutrient pressure, interpreted here as related to frequent recurrences of wet phases during the warm, humid climate of the Uppermost Thanetian, might have promoted temporary dominance of microbes over corals, causing rapid environmentally-driven "phase shifts" in the dominant biota.</ABSTRACT>

89709 <TITLE>Long-term variability in the stable carbon isotopic composition of Porites corals at the northern Gulf of Aqaba, Red Sea.</TITLE>
89710 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 381-382: 1-14.</SOURCE>
89711 <ABSTRACT>To study long-term variations in surface ocean δ13C, we investigated coral skeletal δ13C records of 20 colonies of the shallow-water coral Porites spp. from the northern Gulf of Aqaba and the northern Red Sea. The coral colonies represent different water depths, a wide range of different periods (Last Interglacial, Holocene, the last centuries, the last decades), and various growth rates. Records from modern and fossil corals show irregular seasonal cycles, attributed mainly to the seasonal cycle of light. No attenuation in the amplitude of the seasonal skeletal δ13C cycle with depth is evident, and no significant correlation between mean annual coral δ13C and water depth was observed in the modern corals. The mean coral extension rates show no clear relationship with mean skeletal δ13C values. The average skeletal δ13C value of modern corals was -2.74 ± 0.49‰, offset from both calcite and aragonite equilibrium values by about 5.22‰ and 6.26‰, respectively. Modern corals reveal a clear trend toward lighter skeletal δ13C values since the year 1974. At longer timescales, the skeletal δ13C values from Last Interglacial and Holocene corals and from coral records extending back to the mid- to late 18th century reveal much heavier δ13C values compared to values from 1960 to the present.

The trend toward lighter skeletal $\delta^{13}\text{C}$ values over the last decades can be attributed to changes in the $\delta^{13}\text{C}$ of the dissolved inorganic carbon of the ambient seawater due to the addition of anthropogenically derived CO_2 (^{13}C Suess effect) to the atmosphere. Other factors such as the metabolic effects of corals may account for the modulation of skeletal $\delta^{13}\text{C}$ on shorter timescales. A centuries-long coral record from the northern Red Sea reveals a magnitude of decrease in skeletal $\delta^{13}\text{C}$ comparable to global trends (1960-1990), whereas a centuries-long coral record from the northern Gulf of Aqaba indicates a larger decrease over the same period, probably due to local effects. In conclusion, the combined carbon isotope records obtained from *Porites* spp. corals from the northern Red Sea seem to be suited to provide information on long-term world-wide changes in atmospheric CO_2 .

89722 <TITLE>Coral-crinoid biocoenosis and resulting trace fossils from the Middle Devonian of the Eifel synclines (Rhenish Massif, Germany).</TITLE>

89723 <SOURCE>Journal of Paleontology 86, 2: 282-301.</SOURCE>

89724 <ABSTRACT>Fossil echinoderms are a rich source of information concerning biotic interactions. In this study we analyzed the premortem encrustation of the highly specialized Middle Devonian rugose corals *Aspasmophyllum crinophilum* and ?"Adradosia" sp. on camerate crinoid stems. *Aspasmophyllum* infested living crinoid stems by sclerenchymal outgrowth that formed a skeletal ring but ?"Adradosia" sp. encrusted the stems rapidly, without building a ring. These coral-crinoid biocoenoses indicate a settlement advantage for the rugose corals within densely populated communities of the lower Givetian. The corals could be interpreted as large epizoozoans that benefited as secondary tierers reaching relatively high tiering levels. It also suggests the ability for the affected crinoids to repel the coral by overgrowing the corallite with a local increased stereomic growth. Because the crinoid axial canals are not penetrated, the corals cannot be considered as predators or parasites of crinoids. Therefore, the described biocoenosis is interpreted as commensalism. The species *A. crinophilum* is redescribed, and a neotype is defined, because of the loss of the initial types. Two types of ichnofossils can be attributed to the premortem encrustation of both corals. They are described as *Ostiocavichnus* n. ichnogen. and are attributed to the stereomic response of the infested hosts. These swellings are characterized as either elliptical (*Ostiocavichnus ovalis* n. ichnogen. n. ichnosp. due to the assumed reaction of *A. crinophilum*) or subcircular concavities (*O. rotundatus* n. ichnogen. n. ichnosp. due to the reaction of ?"Adradosia sp.").</ABSTRACT>

89735 <TITLE>Evidence for shallow-water 'Upper Kellwasser' anoxia in the Frasnian-Famennian reefs of Alberta, Canada.</TITLE>
89736 <SOURCE>Lethaia 46, 3: 355-368.</SOURCE>
89737 <ABSTRACT>The Frasnian-Famennian extinction witnessed the global devastation of both level-bottom and reef communities in low latitudes. Marine extinctions in offshore level-bottom communities are associated with two widespread, transgressive, anoxic 'Kellwasser Events' that support an anoxia-extinction link. Typical Kellwasser facies of bituminous limestones and shales are not obviously recorded in shallow-water settings, and thus, it is unclear whether anoxia played a role in reef losses. We evaluate geochemical, petrographic and facies evidence for oxygen restriction from an extremely shallow-water carbonate platform in Alberta. Sequence stratigraphy places the Frasnian-Famennian boundary at a sequence boundary that tops a laminated mudstone and interrupts carbonate platform deposition. Two transgressive pulses have been identified, one of which is associated with the second, major transgression of T-R cycle IID of the Devonian eustatic sea-level curve. Geochemical proxies indicate that these transgressions were accompanied by influx of dysoxic or anoxic waters. Organic carbon and U enrichment in the Frasnian, particularly just below the Frasnian-Famennian boundary, points to episodic dysoxic conditions that probably persisted into the basal Famennian and were coincidental with the global Upper Kellwasser Event. This study provides the first evidence for the smoking gun of an anoxia-driven extinction in very shallow waters, implicating this potent killer in the demise of the Devonian reefs.</ABSTRACT>

89748 <TITLE>Corals on the slope (Aptian, Maestrat Basin, Spain).</TITLE>
89749 <SOURCE>Cretaceous Research 37: 43-64.</SOURCE>
89750 <ABSTRACT>The term "reef" has been frequently misused when applied to fossil coral communities. Our popular but biased view of coral community structure based on the idyllic picture of recent tropical reefs has failed to recognize that, in many fossil examples, alternative states of community structure with no or limited framework may occur. The Aptian colonial scleractinians analysed in the western Maestrat Basin (eastern Spain) constitute an example of non-reef-building coral populations, which thrived in marly slope settings. These corals developed within the photic zone but below the storm wave-base. All colonies are found well-preserved in life position. They are mostly decimetres in size and mainly occur isolated giving rise to a continuous and uniform (dominated by domal and massive forms) unbound growth fabric with a low to medium degree of development (coral skeletal volume = 5-20%). Occasionally, however, colonies growing on top of each other forming small metre-sized bioherms are also present. A total of 21 species were identified. Coral diversity in each sample location varies between three and nine species. These numbers of species are comparable with those exhibited by coeval coral assemblages from other basins of the Tethys, but are comparatively low when compared with diversities exhibited by many Recent and fossil coral communities. The corals studied apparently found optimal ecological conditions for their development on the marly slopes of the western Maestrat Basin. This is primarily expressed in the unusually

large dimensions (up to 2.3m in width) of some of the coral colonies when compared to other Cretaceous occurrences, and in the persistence and resilience of the coral populations. The observed coral genera and species (suborders Archeocaeniina, Faviina, Fungiina and Microsolenina) are very common in the time interval between the Barremian and the Early Albian and most of them have been reported from several other localities in the western and central Tethyan realm. In addition, the coral-bearing levels also contain the poorly known and exotic genera Agrostyliastraea and Procladocora. There are no significant differences at species level or in community structure between the Early and Late Aptian faunas investigated. Therefore, the coral communities as well as the environmental conditions controlling them would have been relatively stable during the time intervals when these corals flourished. An important palaeoecological implication is that comparatively low species diversities and the absence of reef frameworks do not necessarily imply unfavourable environmental conditions for coral growth. Furthermore, this study may serve as an example for the analysis of other level-bottom coral communities displaying a loose growth fabric.</ABSTRACT>

89761 <TITLE>Palaeosols and palaeokarst beneath subaerial unconformities in an Upper Devonian isolated reef complex (Judy Creek), Swan Hills Formation, west-central Alberta, Canada.</TITLE>

89762 <SOURCE>Sedimentology 58: 960-993.</SOURCE>

89763 <ABSTRACT>The isolated Judy Creek reef complex in the Lower Frasnian Swan Hills Formation in west-central Alberta, Canada, contains two subaerial unconformities, R0.5 and R4, which formed as a consequence of relative sea-level falls of at least regional scale. Deposits beneath these unconformities have distinctive palaeosol and palaeokarst features. Comparison of the R0.5 and R4 profiles indicates that the major intrinsic controls on the development and modification of the profiles are parent-material lithology, particularly the prior degree of induration and particle size, the low topographic relief at the top of the reef interior, and limited vegetation of the exposed reef top due to unfavourable growth conditions and geographic isolation. In addition to climate, the major extrinsic controls are the extent of relative sea-level fall, and the degree of shoreface erosion during the ensuing marine transgression. This study highlights the complex interplay of mainly physical and chemical processes influencing the formation of subaerial unconformities in carbonate environments during the Devonian. 89774 <TITLE>Holocene sea-level record from corals: Reliability of paleodepth indicators at Ishigaki Island, Ryukyu Islands, Japan.</TITLE>

89775 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 287, 1-4:

143-151.</SOURCE>

89776 <ABSTRACT>Holocene sea-level change provides direct evidence of the melting of ice sheets; however, our understanding of the timing and course of such change is limited by a lack of information regarding environmental condition of corals. For example, Holocene sea-level curves are compiled based on water depths estimated from the occurrence of a small number of coral species, as species identification is difficult work. The error associated with this method of estimating sea level exceeds ± 2.5 m. In addition, there generally occurs a difference in the living-water depth of corals between high-energy reefs and low- to moderate-energy reefs. This difference in living-water depth also results in an error in reconstructed sea-level curves. In the present study, we analyzed drill core and recorded the vertical distribution of corals at the high-energy Ibaruma reef and low- to moderate-energy Fukido reef, Ishigaki Island, Ryukyu Islands, Japan. Analyses of corymbose *Acropora* (*A. digitifera*), massive *Goniastrea* (*G. retiformis*), massive *Pocillopora* (*P. verrucosa*), massive *Platygyra* (*P. ryukyuensis*), and other corals enables the accurate reconstruction of a sea-level curve because these species are distributed in a narrow range, with a weighted mean (MW) error of between ± 0.5 and ± 2.5 m. These observation data from Ibaruma and Fukido reefs can be used to reconstruct Holocene sea-level curves based on drill core data from Ibaruma reef; however, the two reefs yield contrasting sea-level curves: the curve reconstructed based on data from Fukido reef is several meters deeper than that reconstructed based on data from Ibaruma reef. This discrepancy reflects the different energy levels of the two reefs (high-energy at Ibaruma reef and low- to moderate-energy at Fukido reef). Therefore, the accurate reconstruction of a Holocene sea-level curve requires the identification of species from drill core and observations of the vertical distribution of species at the present-day reef at a location close to the drilling site. The Holocene sea-level curve reconstructed based on drill core data from Ibaruma reef reveals a rapid sea-level rise of approximately 7.5m kyr⁻¹ between 8000 and 6000 cal. years BP. The rate of sea-level rise decreased from 7.5 to 3.5m kyr⁻¹ between 6000 and 5000 cal. years BP. A mid-Holocene highstand occurred at around 5000 cal. years BP, at a level of approximately ± 2.5 m above the present mean sea level. The increase in ocean volume corresponding to this sea-level rise indicates that melting of the Antarctic ice sheet continued beyond 6000 cal. years BP, as most of the Northern Hemisphere ice sheets had melted by 6000 cal. years BP, resulting in sea levels similar to those of the present day.</ABSTRACT>

89788 <SOURCE>Geological Survey of Western Australia Record 2011, 5: 1-11; Perth.</SOURCE>

89789 <ABSTRACT>A robust sequence stratigraphic interpretation of the Late Devonian succession over the outer Lennard Shelf requires a thorough review and integration of petroleum and mineral core, Geological Survey of western Australia outcrop data, Geoscience Australia subsurface interpretations, and recently acquired 3D seismic. The subsurface Late Famennian platform evolution of the outer Lennard Shelf includes features and sequence boundaries that have not been recognised in

outcrop. The reef extinction event is poorly cored and equivocal on well logs, and requires high-resolution biostratigraphy and seismic correlations to be fully resolved. Where identified, it is commonly within an interval with a spiky gamma-ray well log motif that is distinct from its equivalent outcrop response. In the Blina oilfield, a locally developed ramp system briefly replaced a reef-rimmed platform during a widespread backstepping transgressive event of Famennian 2A sequence (postera-expansa conodont zone). This backstepping event has not been recognized in outcrop, but would lie within Nullara Sequence 2. A possible paleokarst zone in Janpam North 1 indicates karsting may be associated with the Famennian 2A/2B sequence boundary (expansa conodont zone), but its outcrop equivalent has similarly not been recognized. Silty carbonates of the 'inner platform' facies dominate Famennian sequence 2B (expansa-praesulcata conodont zone) of the outer Lennard Shelf, but are unlike the Nullara Limestone back-reef facies in outcrop. Paleotopography may have been an important control on the extent of inner platform development on the Lennard Shelf.

89800 <TITLE>The Tindouf Basin, a marine refuge during the Serpukhovian (Carboniferous) mass extinctions in the northwestern Gondwana platform.</TITLE>

89801 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 394: 12-28.</SOURCE>

89802 <ABSTRACT>Several macrofaunas and microfossils of the Carboniferous Saharan basins have longer stratigraphic ranges than those of other basins in the western Palaeotethys realm, particularly in the Tindouf Basin (Morocco-Algeria). Foraminifers are particularly abundant and diverse in the Serpukhovian and basal Bashkirian compared to coeval basins, and some taxa have longer ranges than in the neighbouring Reggan and Bechar basins, although this effect is more marked compared to the western Palaeotethyan assemblages in Europe. Several rugose coral species are recorded from the early Bashkirian that previously were considered to have disappeared in the Serpukhovian. The Tindouf Basin, as one of the most western Saharan basins in North Africa, shows the greatest stratigraphic ranges of taxa which diminish eastwards. Evidence for a mass extinction event during the Serpukhovian in the Tindouf Basin has not been clearly recognized, although a possible influence of glaciation is observed in the faunal diversity. Eustatic sea-level changes were experienced in Tindouf with the cyclic pattern of sedimentation, but warm water ocean currents from the palaeoequator were able to maintain tropical conditions on the platform. Tectonics in the area, led to emerging land masses and barriers, and created a partly isolated basin in this sector of the western part of the Sahara Platform in northern Gondwana. The combination of those factors controlled the environmental conditions in the area, allowing the persistence of the fauna for longer stratigraphic ranges than its equivalent counterparts in the western Palaeotethys.</ABSTRACT>

89813 <TITLE>Magnetic susceptibility and its relationship with
paleoenvironments, diagenesis and remagnetization: examples from the
Devonian carbonates of Belgium.</TITLE>
89814 <SOURCE>Studia Geophysica et Geodaetica 56: 677-704; Prague.</SOURCE>
89815 <ABSTRACT>To better understand the origin of the initial magnetic
susceptibility (χin) signal in carbonate sequences, a rock
magnetic investigation that includes analysis of acquisition curves of
the isothermal remanent magnetization (IRM) and hysteresis parameters,
was undertaken on Devonian carbonates from the Villers and Tailfer
sections, Belgium. Both sections are divided into a lower unit,
dominated by biostromal and external ramp facies (biostromal unit) and
an upper unit, only consisting of lagoonal facies (lagoonal unit). The
variations in χin signal are mainly driven by magnetite variation,
mostly pseudosingle-domain (PSD) magnetite. Clay minerals, pyrite,
hematite and obviously calcite and dolomite are also present but their
contribution to the χin pattern is not significant. There is a
correlation between detrital proxies (Zr, Rb, Al₂O₃, TiO₂) and χin
for the Tailfer biostromal unit and the entire Villers section. The
pervasive presence of fine-grained magnetite is interpreted as related
to remagnetization. In absence of external fluids, the iron released
during the smectite to illite transition remains in situ. In those
situations χin may reflect an inherited primary synsedimentary
signal. In the lagoonal unit of the Tailfer section, remagnetization
appears to have obscured the original detrital information prompting
the need for an evaluation of the composition of the susceptibility
signal for individual case studies.</ABSTRACT>

89826 <TITLE>The Suess effect in Fiji coral δ13C and its potential as a
tracer of anthropogenic CO₂ uptake.</TITLE>
89827 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 370: 30-40.
</SOURCE>
89828 <ABSTRACT>In the context of increasing anthropogenic CO₂ emissions,
determining the rate of oceanic CO₂ uptake is of high interest.
Centennial-scale changes in δ13C of the surface water dissolved
inorganic carbon (DIC) reservoir have been shown to be influenced by
the carbon isotopic composition of atmospheric CO₂. However, the
availability of direct oceanic δ13C measurements is limited and
methods for reconstructing past δ13C variability of the oceanic
DIC are needed. Geochemical reconstructions of DIC variability can help
in understanding how the ocean has reacted to historical changes in the
carbon cycle. This study explores the potential of using temporal
variations in δ13C measured in five Fijian Porites corals for
reconstructing oceanic δ13C variability. A centennial-scale
decreasing δ13C trend is observed in these Fiji corals. Other
studies have linked similar decreasing δ13C trends to
anthropogenic changes in the atmospheric carbon reservoir (the "13C
Suess effect"). We conclude that solar irradiance is the factor
influencing the δ13C cycle on a seasonal scale, however it is not

responsible for the centennial-scale decreasing $\delta^{13}\text{C}$ trend. In addition, variations in skeletal extension rate are not found to account for centennial-scale $\delta^{13}\text{C}$ variability in these corals. Rather, we found that water depth at which a Fijian Porites colony calcifies influences both $\delta^{13}\text{C}$ and extension rate mean values. The water depth- $\delta^{13}\text{C}$ relationship induces a dampening effect on the centennial-scale decreasing $\delta^{13}\text{C}$ trend. We removed this "water depth effect" from the $\delta^{13}\text{C}$ composite, resulting in a truer representation of $\delta^{13}\text{C}$ variability of the Fiji surface water DIC ($\delta^{13}\text{C}_{\text{Fiji-DIC}}$). The centennial-scale trend in this Fiji coral composite $\delta^{13}\text{C}_{\text{Fiji-DIC}}$ time-series shares similarities with atmospheric CO_2 , implicating the $\delta^{13}\text{C}$ Suess effect as the source of the this coral $\delta^{13}\text{C}$ trend. Additionally, our study finds that the $\delta^{13}\text{C}$ variability between the atmosphere and the ocean in this region is not synchronous; the coral $\delta^{13}\text{C}$ response is delayed by ~10 years. This agrees with the previously established model of isotopic disequilibrium between atmospheric CO_2 and oceanic surface water DIC.

89839 <TITLE>A coral Sr/Ca calibration and replication study of two massive corals from the Gulf of Mexico.</TITLE>

89840 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 307, 1-4: 117-128.</SOURCE>

89841 <ABSTRACT>This study examined the variations in the ratio of strontium-to-calcium (Sr/Ca) for two Atlantic corals (*Montastraea faveolata* and *Siderastrea siderea*) from the Dry Tortugas National Park (centered on 24.7°N, 82.8°W) in the Gulf of Mexico. Cores from coral colonies in close proximity (10s of meters) and with the same environmental conditions (i.e., depth and water chemistry) were micro-sampled with approximately monthly resolution and the resulting Sr/Ca variations were calibrated with local sea surface temperature (SST) records. Replication tests for coral Sr/Ca variations found high agreement between intra-colony variations and between individual colonies of *S. siderea* (a single *M. faveolata* colony was sampled). Regression analysis of monthly variations in coral Sr/Ca and local SST revealed significant correlation on monthly and inter-annual timescales. Verification of the calibration on different timescales found coral Sr/Ca-SST reconstructions in *S. siderea* were more accurate than those from *M. faveolata*, especially on inter-annual timescales. Sr/Ca-SST calibration equations for the two species are significantly different (cf., Sr/Ca = -0.042 SST + 10.070, *S. siderea*; Sr/Ca = -0.027 SST + 9.893, *M. faveolata*). Mean linear extension for *M. faveolata* is approximately twice that of *S. siderea* (4.63, 4.31, and 8.31 mm year⁻¹, A1, F1, and B3, respectively); however, seasonal Sr/Ca variability in *M. faveolata* is less than *S. siderea* (0.323, 0.353, and 0.254 mmol mol⁻¹, A1, F1, and B3, respectively). The reduced slope for *M. faveolata* is attributed to physical sampling issues associated with complex time-skeletal structure of *M. faveolata*, i.e., a sampling effect, and not a growth effect since the faster growing *M. faveolata* has the reduced Sr/Ca variability.</ABSTRACT>

89852 <TITLE>Improving coral-base paleoclimate reconstructions by replicating
350 years of coral Sr/Ca variations.</TITLE>
89853 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 373: 6-24.
</SOURCE>
89854 <ABSTRACT>Coral-based climate reconstructions are typically based on a
single record and this lack of replication leads to questions in
regards to chronology accuracy and reliability of the inclusive
geochemical variations to record climate viability. Here we present two
multi-century coral Sr/Ca records recovered from a Porites lutea colony
offshore of Amédée Island, New Caledonia (22°28.8'S, 166
°27.9'E). The chronology was developed by cross dating the coral
Sr/Ca time series and verifying the chronology with high precision
absolute ²³⁰Th dating. We identify chronological discrepancies of -2.3
and +3.7 years century⁻¹ for reconstructions based on a single core
with uncertainty increasing after ~250 years. We assess the impact of
Porites skeletal architecture on coral geochemistry by characterizing
centimeter-scale architectural structures with respect to sampling.
Optimal sampling paths are those on the slab surface parallel to the
growth direction of individual corallites along the central axis of an
actively extending corallite fan. Coral Sr/Ca time series extracted
from optimal skeletal structures are highly reproducible with a mean
absolute difference of 0.021 mmol mol⁻¹ or 0.39 °C for monthly
determinations. Suboptimal skeletal architecture is characterized by
corallites extending through the slab surface, and the coral Sr/Ca
determinations derived from suboptimal paths tend to produce a warm
bias that varies between +0.04 and +2.30 °C. Disorganized skeletal
architecture is characterized by small, terminating, or unclear
corallite fans that produce a cold bias of -0.11 to -2.45 °C in
coral Sr/Ca determinations. These problematic architecture types also
produce biases in coral δ180 determinations, but to a lesser
extent. We assess the impact of sampling a coral colony along paths
that vary from vertical to horizontal in large and small Porites
colonies with extension rates >6 mm year⁻¹ and we determine there is no
significant difference in the coral Sr/Ca records.</ABSTRACT>

89865 <TITLE>Facies and Palaeoecology of the upper Member of the Aisemont
formation (Late Frasnian, S. Belgium): an unusual episode within the
Late Frasnian crisis.</TITLE>
89866 <SOURCE>Geologica Belgica 13, 3: 197-212.</SOURCE>
89867 <ABSTRACT>The upper member of the Aisemont Formation - also known as
the "second biostrome" - is the last significant Upper Frasnian
carbonate unit in the northern part of the Namur-Dinant Basin (Southern
Belgium). It consists of bioclastic limestone, often dolomitized, with
numerous oncoids and corals. Despite its local name, the member is not
a biostrome because only one thin bed is constructed by corals. It is
mainly composed of limestone with numerous oncoids and a rich fauna of

opportunistic organisms (bryozoans, brachiopods, gastropods, sponges, etc.) where *Phillipsastrea* and *Frechastraea* are the dominant coral taxa, associated with *Alveolites*. Ragged colonies of corals, as well as multi-encrusted bodies, show that the sea floor was soft and the rate of sedimentation was seasonal. These factors were unfavourable to common reef builders (stromatoporoids), thus the occurrence of one bed constructed by corals is a remarkable event that corresponds to the colonization of a hard ground defining the base of a falling stage systems tract. This confirms the model of the Aisemont sequence (third-order transgression-regression cycle). The abundant development of microbial structures in the member (oncoids) and in its lateral equivalent in stromatolites and thrombolites of the Petit-Mont Member (Les Valisettes Formation) in the Philippeville Anticlinorium is interpreted as an evidence of the environmental deterioration corresponding to the Late Frasnian Crisis. </ABSTRACT>

89878 <TITLE>Endobiotic cornulitids in Upper Ordovician tabulate corals and stromatoporoids from Anticosti Island, Quebec.</TITLE>

89879 <SOURCE>Journal of Paleontology 84, 3: 518-528.</SOURCE>

89880 <ABSTRACT>Conoidal shells of *Cornulites celatus* n. sp. occur commonly within host coralla of *Propora conferta* Milne-Edwards and Haime, 1851, sensu lato, from the Laframboise Member of the Ellis Bay Formation (Ashgill: Upper Ordovician) at Pointe Laframboise on western Anticosti Island. Examples have also been found at the same locality in the tabulate corals *Paleofavosites* sp., *Acidolites arctatus* Dixon, 1986, and *A. compactus* Dixon, 1986, and the stromatoporoid *Ecclimadictyon* sp., but not in other associated tabulate coral species. Growth interference between the shells and their hosts indicates a commensal relationship. *C. celatus* apparently had a more limited paleoenvironmental range than its principal coral host species, which occurs abundantly elsewhere on the island without its endobiotic partner. The diagnosis of *Cornulites* is emended to include forms having a two-layered shell wall with a distinctive outer layer consistently preserved as prismatic calcite. This new species extends the known stratigraphic range of cornulitids in commensal relationships with corals and stromatoporoids from the Silurian back to the Upper Ordovician.</ABSTRACT>

89904 <TITLE>Bryozoan Fauna from the Lower Devonian (Middle Lochkovian) of Sierra de Guadarrama, Spain.</TITLE>
89905 <SOURCE>Journal of Paleontology 86, 1: 60-80.</SOURCE>
89906 <ABSTRACT>A bryozoan fauna containing 11 species is described from the Lower Devonian (middle Lochkovian) of Arroyo del Agua, Sierra de Guadarrama, Guadalajara, Spain. One genus containing one species is new: rhabdomesine cryptostome Fehlerpora insolita n. gen., n. sp. Six additional new species are described: three cystoporates: Cystiramus gracilis n. sp., Fistuliramus guadarramaensis n. sp., and Fistuliphragma tenuis n. sp.; and three trepostomes: Eridotrypella hispanica n. sp., Boardmanella dubia n. sp., and Leptotrypella inesae n. sp. Four further trepostome species were identified: Leioclema incompositum Duncan, 1939, Minussina spinosoformis Astrova, 1964b, Leptotrypella verisimilis Astrova, 1970, and Leptotrypella vulgata Astrova, 1964b. The association is distributed over three different sedimentary environments. The high-energy one representing accumulation of debris from bryozoan-coral-pelmatozoan thickets contains eight species dominated by erect branched forms (six species). Tabulate corals are present, especially branches which most likely belong to Subcladopora? abnormis (Mironova, 1974). The environment with moderate to low wave influence contains only two bryozoan species, one erect branched and one encrusting. The third setting represents bryozoan thickets in situ situated in deeper water, the most tranquil environment characterized by four bryozoan species, dominated by three erect forms. Fenestrate bryozoans are absent from the two higher energy environments, whereas the bryozoan thickets in deeper water contain rare unidentified fragments of fenestrates. The bryozoan fauna shows distinct relations to the Lower Devonian (Lochkovian) of Ukraine, one species is known from the Middle Devonian of U.S.A. </ABSTRACT>

89917 <TITLE>Bryozoans, corals, and microfacies of Lower Eifelian (Middle Devonian) limestones at Kierspe, Germany.</TITLE>
89918 <SOURCE>Facies 58: 727-758.</SOURCE>
89919 <ABSTRACT>The Lower Eifelian Meinerzhagener Korallenkalk (= upper Cultrijugatus Beds) at Kierspe, Sauerland, contains a rich reefal fauna. Eight bryozoan species are described, two of them are new: the cystoporate Fistuliporella kierspensis n. sp. and the trepostome Leptotrypella sophiae n. sp. The bryozoans from the Meinerzhagener Korallenkalk show distinct similarities to the Lower-Middle Devonian of Spain (Santa Lucía Formation, Emsian-Eifelian), and to the Middle

Devonian (Eifelian) of Transcaucasia. The coral fauna comprises five tabulate corals and one rugose coral that document a paleobiogeographic relationship between Central and Eastern Europe and Central Asia. The associated fauna is represented by brachiopods, ostracods, and echinoderms. The studied limestones also commonly contain calcimicrobes represented by three species. The faunal and microfacial characteristics indicate a shallow marine depositional environment just above the storm wave base, with a supposed depth of 20 m, within the photic zone. The nutrient regime was at least a mesotrophic. The upper boundary of the Cultrijugatus Beds coincides with the Chotec-Event that strongly affected brachiopods, whereas corals and bryozoans were insensitive to this event.</ABSTRACT>

89931 <SOURCE>Ferrantia 58: 5-63; Luxembourg.</SOURCE>

89932 <ABSTRACT>A multitude of new finds permit a fundamental revision of the fossil contents of the Wiltz layers. For this purpose, approx. 5,700 proofs of finds were evaluated. Due to the numerous finds, the study will be published in several parts. It turns out that the species-diversity is very much greater than assumed to date. The presence of many of genera and species known from other sedimentation areas have now been proved for the Wiltz-layers in the Wiltz-basin and Daleiden Synclinal Group. This publication includes plant fossils, *Rhaphidopora* sp. cf. *Rhaphidopora lonsdalei*, *Cornulites* sp. and *Pterygotoidea* fam. et gen. et sp. indet. The trilobite *Leonaspis grafi* n. sp. is redescribed. Finally, the area examined can be defined as an extensive long-lived deposit region of a shallow water situation extending from close to and far from the coast of the Ardenno-Rhenish continental shelf with multifold faunistic correspondences to other regions in the Variscan sea during the upper Emsian.</ABSTRACT>

89943 <TITLE>Post-mortem and symbiotic Sabellid and Serpulid-coral associations from the Lower Cretaceous of Argentina.</TITLE>

89944 <SOURCE>Revista Brasileira de paleontologia 14, 3: 215-228.</SOURCE>

89945 <ABSTRACT>One morphotype of sabellids (Sabellida, Sabellidae) and two of serpulids (Sabellida, Serpulidae), found as encrustations on scleractinian ramose corals of the species *Stereocenia triboleti* (Koby) and *Columastrea antiqua* Gerth, from the Agrio Formation (early Hauterivian) from Neuquén Basin, Argentina, are described. The identified morphotypes, *Glomerula lombricus* (DeFrance), *Mucroserpula mucroserpula* Regenhardt and *Propomatoceros sulcicarinatus* Ware, have been previously recorded from the Early Cretaceous of the northern

Tethys. Two different type of sabellid and serpulid-coral associations have been recognized. The first and more abundant association corresponds to post-mortem encrustation on corals branches. The second one corresponds to a symbiotic association between the serpulid *P. sulcicarinatus* and both species of corals. The serpulid tubes are recorded parallel to the coral branches reaching the upper tip of them and they were bioimmured within the coral as they grew upwards. The studied symbiotic relationship between serpulids and corals may be regarded as a mutualism as both members probably benefited each other. This type of association has similarities with recent cases of symbiosis between serpulids and corals, but had no fossil record until now.

89956 <TITLE>A new coral-associated decapod assemblage from the Upper Miocene (Messinian) Upper Coralline Limestone of Malta (Central Mediterranean).</TITLE>

89957 <SOURCE>Palaeontology 53, 6: 1315-1348.</SOURCE>

89958 <ABSTRACT>A rich coral-associated decapod assemblage is recorded from the 'Depiru Beds' of the upper part of the Upper Coralline Limestone (Messinian, Upper Miocene), from the island of Malta. Nineteen species within 17 genera have been discovered, where 14 genera are new for Malta. Four new species are described, namely *Micippa annamariae* sp. nov., *Pilumnus scaber* sp. nov., *Panopeus muelleri* sp. nov. and *Herbstia melitense* sp. nov. *Herbstia melitense* sp. nov. constitutes the first record of the genus from the fossil record in the Mediterranean region. This discovery more than doubles the number of known fossil decapod species from Malta. The fossil bivalve *Jouannetia* (J.) *semicaudata* Des Moulins, 1830 and the extant decapod *Maja goltziana* D'Oliveira, 1888, are also recorded for the first time from Malta. Other Neogene coral-associated decapod assemblages are investigated and correlated with the new assemblage from Malta. The migration of taxa between the Mediterranean region and the Paratethys, particularly during the Lower Badenian (Langhian), is evidenced by the strong affinity of the Maltese decapod assemblage with that of the Middle Miocene Badenian assemblages from Hungary, Poland and Ukraine. Upper Miocene, Messinian assemblages from Spain, Algeria and Morocco are also similar to that from Malta.</ABSTRACT>

89969 <TITLE>Geochemistry and skeletal structure of *Diploria strigosa*, implications for coral-based climate reconstruction.</TITLE>

89970 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 298, 3-4: 378-387.</SOURCE>

89971 <ABSTRACT>Geochemical tracers incorporated into the skeleton of reef-building corals are ideal proxies for reconstructing environmental

parameters of ambient seawater such as temperature and salinity at subseasonal resolution. However, validation concerns of these environmental proxies due to the complex skeleton of some tropical Atlantic corals have hindered such coral-based environmental reconstructions in this region compared to the tropical Pacific. In order to identify complications associated with the complex skeletal architecture of the massive brain coral *Diploria strigosa*, we performed microsampling experiments along and across individual skeletal elements. We demonstrate that the mesoscale heterogeneity of Sr/Ca, $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$ is a systematic feature of *D. strigosa* and is linked to different vital effects between skeletal elements. The thecal wall is significantly depleted in Sr, $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$ compared to the adjacent septa and columella and differences between apparent temperature signatures of several degrees are greater for Sr/Ca suggesting that this temperature proxy is more sensitive to skeletal mixing than $\delta^{18}\text{O}$. Parallel subseasonal microsampling experiments performed along individual skeletal elements of a single corallite of a *D. strigosa* coral which grew at a rate of 0.65 cm/year allow for investigating potential biases associated with its complex skeletal mesoarchitecture. Highest correlation between Sr/Ca and $\delta^{18}\text{O}$ from skeletal material retrieved from the centre of the thecal wall suggests that microdrilling the theca provides the best environmental signal compared to adjacent microsampling profiles. Moreover, based on monthly-mean climatology, the temperature dependence of Sr/Ca for this profile is comparable to previous calibrations published from faster growing *D. strigosa*. Based on these results, we conclude that accurate microsampling along the centre of the thecal wall of *D. strigosa* is a prerequisite for generating robust climate reconstructions from its skeleton.

89982 <TITLE>Indo-Pacific and Atlantic spurs and grooves revisited: the possible effects of different Holocene sea-level history, exposure, and reef accretion rate in the shallow fore reef.</TITLE>

89983 <SOURCE>Facies 56, 2: 173-177.</SOURCE>

89984 <ABSTRACT>Shallow fore-reef areas worldwide are usually characterized by spurs and grooves. A comparison of examples from the three world oceans suggests that Indo-Pacific spurs and grooves are shaped predominantly by erosion, whereas western Atlantic spur and groove systems are largely a product of constructive processes. I propose that this difference is caused by regional differences in Holocene sea-level change, which controlled exposure to waves and currents, and reef-accretion rates. The transgressive-regressive sea-level curve in the Indo-Pacific realm, i.e., the Mid-to-Late Holocene sea-level fall in these areas has maintained high-energy conditions in the shallow fore reef. Higher exposure to waves and currents favors erosion and leads to a dominance of crustose coralline algae that have relatively slow growth rates. In the western Atlantic, the transgressive Holocene sea level has caused Mid-to-Late Holocene deepening and has maintained accommodation space for reef accretion. Fast-growing acroporid corals thrive under lower exposure and are more common than coralline algae. The fossil record of the spur and groove system is rather poor, which is probably a consequence of the need of excellent, three-dimensional outcrops for identification.</ABSTRACT>

89995 <TITLE>Hettangian corals of the Isle of Skye (Scotland): An opportunity
to better understand the palaeoenvironmental conditions during the
aftermath of the Triassic-Jurassic boundary crisis.</TITLE>
89996 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 376: 132-148.
</SOURCE>
89997 <ABSTRACT>At Ob Lusa (Isle of Skye, Scotland), six distinct coral beds
were observed in a modern outcrop where a Hettangian succession is
exposed. The coral associations are monogenic, belonging to
Lepidophyllia, a massive cerioid genus. The lowest bed has relatively
well-developed colonies that form small bioconstructions, whereas the
other beds have small and dispersed colonies that are completely
drowned in the matrix. Their morphology and size can vary, but the
general growth fabric is dominated by platy colonies. This type of
growth fabric is defined as a platestone. The most surprising
characteristic of these specimens, especially for the platy corals, is
their growth pattern; many samples do not exhibit the classical growth
polarity because they are bifacial. Geochemical analyses (δ180,
δ13C) were conducted on oyster shells that were associated with
the corals. The results indicate that the mean palaeotemperature was
approximately 22 °C. Sedimentological analysis revealed shallow
settings where the hydrodynamic energy and siliciclastic inputs
fluctuated. The general faunal assemblage of the outcrop had low
diversity and was mainly composed of allochthonous bioclasts. The
corals at Ob Lusa clearly did not live under ideal environmental
conditions for the development of corals.</ABSTRACT>

90008 <TITLE>Evaluation of the effect of diagenetic cements on element / Ca
ratios in aragonitic Early Miocene (~16 Ma) Caribbean corals:
Implications for ‘deep-time’ palaeo-environmental
reconstructions.</TITLE>
90009 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 369: 185-200.
</SOURCE>
90010 <ABSTRACT>Early Miocene corals (Siderastrea conferta and Montastraea
limbata) from the Paraguana Peninsula, Venezuela and a modern coral (S.
radians) from Bermuda were examined in order to quantitatively assess
the effect of skeletal preservation on element / Ca proxies used for
palaeo-environmental reconstructions. The biostratigraphic age
(Burdigalian) of the corals was confirmed via Sr isotope stratigraphy
to 16.5 ± 0.4 Ma. Light and scanning electron microscopy revealed
the presence of aragonite and calcite cements in both fossil and modern
corals, but brucite cements were found only in the modern coral. Cement
distribution is very heterogeneous, resulting in zones of excellent
preservation juxtaposed with less well preserved regions in both modern

and fossil coral. Oil-filled pore spaces were noted in the fossil specimens. Targeted LA-ICPMS depth profile analyses showed significant differences in Sr/Ca, Mg/Ca, B/Ca, Ba/Ca and U/Ca in aragonite and calcite cements compared to primary skeletal aragonite. Increased Sr/Ca and decreased Mg/Ca ratios were found in aragonite cements compared to skeletal aragonite, whereas in calcite cements these trends were reversed. B/Ca ratios were lower in both aragonite and calcite cements compared to primary aragonite. Estimates of the effect of 1% contamination by aragonite cements on coral Sr/Ca, Mg/Ca, B/Ca and U/Ca palaeo-sea-surface-temperature reconstructions for the fossil corals produced anomalies of -1.2 ± 0.1 , -0.2 ± 0.1 , $+0.3\pm 0.1$ and -0.1 ± 0.1 respectively. Similar percentage calcite cement contamination produced temperature anomalies of $+1.7\pm 0.1$, $+2.7\pm 0.1$, $+0.3\pm 0.1$ and -0.1 ± 0.1 . Because of both highly elevated and depleted Ba/Ca signatures in aragonite and calcite cements respectively, care has to be exercised when reconstructing past flood or upwelling events from fossil corals. When using targeted spatially-resolved analysis, well-preserved early Miocene corals may overall yield reliable deep-time palaeo-proxy information in much the same way as commonly utilised Holocene/Pleistocene corals.

90021 <TITLE>Epi- and endobionts on and in free-living colonies of *Manicina areolata* (Cnidaria, Scleractinia): a comparison of two Pleistocene communities from southern Florida.</TITLE>

90022 <SOURCE>Palaios 25, 6: 400-414.</SOURCE>

90023 <ABSTRACT>The epi- and endobiont communities (EEBCs) found within an exquisitely preserved collection of 48 *Manicina areolata* specimens from two Pleistocene localities in southeastern Florida, United States, were examined in detail. The EEBCs include a broad taxonomic spectrum of encrusting and boring organisms, but differ markedly between the two localities. Specimens from the Canal locality generally show an equitable distribution of EEBCs, with serpulids, spirorbids, and/or chamids numerically dominant and chamids dominating in average area, whereas the Palm Beach Aggregates (PBA) coralla have a much less even distribution of EEBC constituents and lithophagids numerically and spatially dominate virtually all bases. Given the relative proximity of the two localities and inferred distance from the Pleistocene shoreline, it seems unlikely that any of the EEBC components would have been substantially less available in one locality as compared to the other. Therefore, we favor an explanation focused on sedimentologic differences between the two areas. The Canal environment was shelly, carbonate mud, in contrast to the shelly, coarser-grained siliciclastic sediment present at PBA. The substrate at the Canal site was relatively soft, which resulted in corallum basal morphology commencing with a prominent apical cone, whereas the substrate at the PBA site was firmer and this support produced much flatter bases as well as allowing for a substantially greater number of lithophagid bivalves to bore into the coralla.</ABSTRACT>

90034 <TITLE>Formation of deglacial microbialites in coral reefs off Tahiti (IODP 310) involving sulfate-reducing bacteria.</TITLE>
90035 <SOURCE>Palaios 25, 10: 618-635.</SOURCE>
90036 <ABSTRACT>During IODP Expedition 310 (Tahiti Sea Level), drowned Pleistocene-Holocene barrier-reef terraces were drilled on the slope of the volcanic island. The deglacial reef succession typically consists of a coral framework encrusted by coralline algae and later by microbialites; the latter make up ≤80% of the rock volume. Lipid biomarkers were analyzed in order to identify organisms involved in reef-microbialite formation at Tahiti, as the genesis of deglacial microbialites and the conditions favoring their formation are not fully understood. Sterols plus saturated and monounsaturated short-chain fatty acids predominantly derived from both marine primary producers (algae) and bacteria comprise 44 wt% of all lipids on average, whereas long-chain fatty acids and long-chain alcohols derived from higher land plants represent an average of only 24 wt%. Bacterially derived mono-O-alkyl glycerol ethers (MAGES) and branched fatty acids (10-Me-C16:0; iso- and anteiso-C15:0 and -C17:0) are exceptionally abundant in the microbial carbonates (average, 19 wt%) and represent biomarkers of intermediate-to-high specificity for sulfate-reducing bacteria. Both are relatively enriched in ^{13}C compared to eukaryotic lipids. No lipid biomarkers indicative of cyanobacteria were preserved in the microbialites. The abundances of Al, Si, Fe, Mn, Ba, pyroxene, plagioclase, and magnetite reflect strong terrigenous influx with Tahitian basalt as the major source. Chemical weathering of the basalt most likely elevated nutrient levels in the reefs and this fertilization led to an increase in primary production and organic matter formation, boosting heterotrophic sulfate reduction. Based on the observed biomarker patterns, sulfate-reducing bacteria were apparently involved in the formation of microbialites in the coral reefs off Tahiti during the last deglaciation.</ABSTRACT>

90047 <TITLE>Rapid 20th century warming in the Caribbean and impact of remote forcing on climate in the northern tropical Atlantic as recorded in a Guadeloupe coral.</TITLE>
90048 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 296, 1-2: 111-124.</SOURCE>
90049 <ABSTRACT>We have generated 104-year long (1895-1999) monthly δ180 and Sr/Ca time series from a fast-growing *Diploria strigosa* coral core drilled off Guadeloupe Island, Lesser Antilles. Coral Sr/Ca reliably records interannual to decadal surface air temperature (SAT) variations in the region and shows a pronounced warming of approximately 1.5°C since 1950, with the strongest warming (1.2°C) occurring since 1975. This warming is also evident in SAT measured at Guadeloupe, which ends in 1951. Thus, our Sr/Ca series extends the air temperature record by 56 years. We find that the past few decades are the warmest years over the entire period of record. The accelerated warming since 1950 is accompanied by a pronounced decrease in regional precipitation. This

dampens the warming signal indicated by coral $\delta^{18}O$, which is too low (only 0.7–0.8‰ since 1951). Consistently, $\delta^{18}O_{SW}$ estimated from the coral proxies also shows a strong decrease since 1950. Our data suggest an inverse relationship between SAT and precipitation (i.e. warmer and drier) for the latter half of the 20th century with the strongest trends since the mid-1970s. This is consistent with recent observational and model data, which report that while over the tropical oceans rainfall has increased due to an increase in sea surface temperatures, precipitation over land regions is reduced. A continuation of this warming and drying trend over Caribbean land regions would have severe societal consequences, especially in the context of anthropogenic warming. * The El Niño Southern-Oscillation (ENSO) and the North Atlantic Oscillation (NAO) are the two major climate modes affecting large-scale SST variability in the northern tropical Atlantic. Both Sr/Ca and $\delta^{18}O$ show a close relationship to ENSO and the NAO. A quantitative comparison between extremes in mean March–May coral $\delta^{18}O$ and the Niño3 and NAO indices imply that climate variability in the northern tropical Atlantic is mainly forced by tropical Pacific and North Atlantic variability. Spectral analysis suggests that the relative importance of ENSO and the NAO is frequency dependent, with ENSO dominating at interannual, and the NAO dominating at interdecadal time scales.

90060 <TITLE>Devonian rugose coral 'Amplexus' and its relation to submarine fluid seepage.</TITLE>

90061 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 386: 180–193.</SOURCE>

90062 <ABSTRACT>The rugose coral 'Amplexus' occurs frequently in the sedimentary cover of the Devonian submarine volcanic intrusion in the eastern Anti-Atlas, southern Morocco. This study elucidates the palaeoecology of 'Amplexus', which forms very rich and mostly monospecific, spot assemblages within the Lower and Middle Devonian carbonates. Geological and isotopic evidences show that these associations developed at hydrothermal vents and at a cold seep site. The assemblages are always spatially associated with micritic carbonate bodies, occurring within bedded, hemipelagic deposits. The 'Amplexus' corals preferred locations in the close proximity of submarine hydrothermal fluid seepage, but they generally avoided places with the most elevated temperatures. The corals colonised also a hydrocarbon seep, probably only in its terminal phase of development, when the fluid flow was still at least periodically active. This was only possible as a result of the corals following a calice-in-calice growth, developed due to the environmental toxicity, which facilitated selective survival of larvae that settled in the shelter of empty calices. The 'Amplexus' corals appear to have constituted ecological opportunists, thriving in the nutrient-rich, venting- and seepage-affected areas that were hostile for other benthic organisms. It can be suspected that the unusual, extremely simplified morphology of 'Amplexus' made it particularly well adapted to living in environments typified by harsh and unstable conditions.</ABSTRACT>

90073 <TITLE>Cryptic coral-crinoid "hanging gardens" from the Middle Devonian of southern Morocco.</TITLE>
90074 <SOURCE>Geology: online since 13 December 2013 as doi 10.1130/G35217.1</SOURCE>
90075 <ABSTRACT>An unusual and exceptionally well preserved cryptic community of cnidarians, crinoids, sponges, and microbes developed in a submarine cavity of Middle Devonian age in the Hamar Laghdad area (Morocco). The biota encrusted the cavity roof and grew predominantly in an upside-down position, forming spectacular "hanging gardens." The investigated assemblage differs strikingly from both its Paleozoic and modern analogues; it constitutes one of a very few known examples of fossil cryptic assemblages developed in relatively deep water settings, and is the first report of a cryptic paleoecosystem dominated by rugose corals. The results support the view that during the middle Paleozoic there was no distinct polarization between open-surface and cryptic faunas in deep-water environments, but keen competition for space already existed in Devonian cryptic assemblages. The regional species pool seems to have been the main determinant of the ecological succession and structure of this cryptic community.</ABSTRACT>

90086 <TITLE>Upper Devonian shoal-water delta integrated with cyclic back-reef facies off the Mowanbini Archipelago (Canning Basin), Western Australia.</TITLE>
90087 <SOURCE>Facies 59, 4: 991-1009.</SOURCE>
90088 <ABSTRACT>The Oscar Range in Western Australia's Canning Basin exhibits folded Proterozoic, quartzite, quartzite conglomerate, phyllite, and metavolcanic rocks that survive with positive relief. Facies of the Pillara Limestone were deposited around this relief during Late Devonian (Frasnian) time. A segment of the Great Devonian Barrier Reef with a linear reef margin strikes parallel to the outer paleoislands in the Mowanbini Archipelago. A more sheltered strait separates inner islands from the cratonic Devonian mainland on the Kimberley Block. Large fandelas emanated from the craton, but locally small shoalwater deltas prograded from a drainage basin on one of the larger paleoislands in the Oscar Range. That island is expressed today by local topography exhumed from beneath a cover of former Devonian, Carboniferous, and Permian strata. The Devonian shoal-water delta rests unconformably on tilted Proterozoic phyllite and incorporates abundant phyllitic debris accumulated under fluvial to shoreface conditions. Some quartzite pebbles and hydrothermal quartz were derived from a source more than a kilometer away. Rare gastropods and stromatoporoid fragments in the deltaic sediments were abraded from the adjacent reef margin. The clast-supported conglomerate in the exposed shoal-water delta is mapped over a distance of 130 m to within 15 m of the inner reef margin, exposed nearby on steeply dipping phyllite. A cyclic

succession of mixed clastic and carbonate parasequences, 31.5 m in thickness, follows above a disconformity surface on the delta-top facies. The overall succession represents a minor fall in relative sea level associated with erosion of delta facies and a major transgression characterized by a retrograde parasequence stacking pattern. The succession shifts through siliciclastic-rich shoreface to intertidal distal back-reef facies, ending with a subtidal, siliciclastic-poor proximal back-reef facies. The study demonstrates how variability in sedimentary cycles is influenced by local paleogeographic constraints in an island system dominated by quartzite highlands and phyllite lowlands.</ABSTRACT>

90099 <TITLE>High resolution biostratigraphy of the Tournaisian-Visean boundary interval in the North Staffordshire Basin and correlation with the South Wales-Mendip Shelf.</TITLE>

90100 <SOURCE>Bulletin of Geosciences 87, 3: 497-541.</SOURCE>

90101 <ABSTRACT>A study of three carbonate sections in the North Staffordshire Basin and two in the South Wales-Mendip Shelf yielded so far the richest foraminiferal associations at the Tournaisian-Visean boundary in Western Europe enabling a very good correlation with the stratotype area in South China. The biostratigraphic study was refined by sedimentological and gamma-spectrometrical data in order to define and calibrate the high resolution biostratigraphy across the boundary interval. The study illustrates the cryptic entry of the stratigraphically important species of the Chadian index genus Eoparastaffella which is abundant in photozoan facies. Across the Tournaisian-Visean boundary, changes in the character of the foraminiferal associations reflect the gradual change from heterozoan dominated late Tournaisian ramps to Visean photozoan dominated platforms. The combined application of biostratigraphic and sedimentological methods and gamma ray manifestation of the mid Avonian sequence boundaries have proved useful in the identification of the Tournaisian-Visean boundary in Carboniferous successions on either side of the Wales-Brabant Massif and has widespread applicability for successions of a similar age across Western Europe.</ABSTRACT>

90112 <TITLE>Late Chadian-Early Arundian high-resolution biostratigraphy in the Ogmores-by-Sea section (South Wales-Mendip shelf) and the mid-Avonian unconformity.</TITLE>

90113 <SOURCE>Journal of the Geological Society, London
<http://dx.doi.org/10.1144/jgs2013-023></SOURCE>

90114 <ABSTRACT>The study of the foraminiferal fauna in the Ogmores section in south Wales produced a detailed late Chadian-early Arundian biostratigraphy and sequence stratigraphy with a higher resolution than

in the Arundian stratotype in Hobbyhorse Bay. The earliest Visean (late Chadian) pedogenic horizon close to the Gully Oolite and Caswell Bay Mudstone boundary (MFZ9) corresponds to the mid-Avonian unconformity. The entry of primitive archaedisks of MFZ10 within the Caswell Bay Mudstone is followed by more advanced archaedisks of MFZ11 at the base of the High Tor Limestone. The mid-Avonian unconformity at the Chadian-Arundian boundary is not confined to the London-Brabant Massif, but is also present in central Europe, the East European Platform, the Urals, west Siberia and probably also in Kuzbass and North America. The global extent of the the mid-Avonian unconformity suggests that it is a consequence of early to mid-Visean glacioeustacy. </ABSTRACT>

90138 <TITLE>Marine benthic invertebrates from the Upper Jurassic of northern Ethiopia and their biogeographic affinities.</TITLE>

90139 <SOURCE>Journal of African Earth Sciences 59, 2-3: 195-214.</SOURCE>

90140 <ABSTRACT>We present the first modern description of corals, brachiopods and bivalves from the Antalo Limestone in the Mekele Outlier of northern Ethiopia. This fauna is largely of Oxfordian age and lived in shallow subtidal environments and in small patch reefs. In combining our new data with fossil occurrence data from the Paleobiology Database, we conducted multidimensional scaling analyses to assess biogeographic patterns and the delineation of the Ethiopian Province for the Callovian to Kimmeridgian stages. Results suggest that an Ethiopian Province is indeed evident for our focal groups, but this is more confined than traditionally assumed. The so defined Ethiopian Province includes Tunisia, the Levant, Arabia and much of East Africa, but excludes Tanzania and India. The special status of India and Tanzania is perhaps due to latitudinal gradients in faunal composition.</ABSTRACT>

90151 <TITLE>Testing coral-based tropical cyclone reconstructions: An example
from Puerto Rico.</TITLE>
90152 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 307, 1-4:
90-97.</SOURCE>
90153 <ABSTRACT>Complimenting modern records of tropical cyclone activity
with longer historical and paleoclimatological records would increase
our understanding of natural tropical cyclone variability on decadal to
centennial time scales. Tropical cyclones produce large amounts of
precipitation with significantly lower δ180 values than normal
precipitation, and hence may be geochemically identifiable as negative
δ180 anomalies in marine carbonate δ180 records. This study
investigates the usefulness of coral skeletal δ180 as a means of
reconstructing past tropical cyclone events. Isotopic modeling of
rainfall mixing with seawater shows that detecting an isotopic signal
from a tropical cyclone in a coral requires a salinity of ~33 psu at
the time of coral growth, but this threshold is dependent on the
isotopic composition of both fresh and saline end-members. A comparison
between coral δ180 and historical records of tropical cyclone
activity, river discharge, and precipitation from multiple sites in
Puerto Rico shows that tropical cyclones are not distinguishable in the
coral record from normal rainfall using this approach at these sites.

90177 <TITLE>Early Cretaceous record of microboring organisms in skeletons of growing corals.</TITLE>
90178 <SOURCE>Lethaia 45, 1: 34-45.</SOURCE>
90179 <ABSTRACT>A spectacularly preserved assemblage of microbial euendoliths, penetrating into skeletons of growing scleractinian corals, has been recognized in Early Aptian (Early Cretaceous) reef limestone of the Rarau Mountains (East Carpathians, NE Romania). Microboring euendolithic filaments were found in five coral colonies of the suborder Microsolenina. They remained in part well-preserved, often impregnated with iron oxides, which made them visible even in strongly recrystallized parts of coral skeletons. Filaments of a wide range of sizes (2-40μm in diameter) were concentrated within medium parts of coral septa, oriented along the septa in the direction of the coral growth. The larger filaments were tubular, occurring in bundles and branched into finer, often tapering branches. Their behaviour and organization were quite similar to the modern euendolithic siphonlean chlorophyte *Ostreobium*. Filament diameters exceeded those reported for the modern species, but covered a similarly wide size range. Narrower frequently branching filaments, 4-8μm in diameter, resemble distal branching patterns of modern *Ostreobium quekettii*. Some very thin filaments (ca. 1-2μm) observed within skeleton or inside the large tubular filaments, sometimes associated with globular swellings, may represent euendolithic fungi. The recrystallization of coral skeleton had limited effect on preservation of euendoliths due to their impregnation with iron oxides; microbial euendoliths were subjected to different taphonomic changes.</ABSTRACT>

90190 <TITLE>Effect of the surgeonfish *Ctenochaetus striatus* (Acanthuridae) on the processes of sediment transport and deposition on a coral reef in the Red Sea.</TITLE>
90191 <SOURCE>Facies 57, 2: 215-221.</SOURCE>
90192 <ABSTRACT>Excessive sedimentation is a major threat to coral reefs. It can damage or kill reef-building corals and can prevent the successful settlement of their planktonic larvae. The surgeonfish *Ctenochaetus striatus* feeds on rocky surfaces by sweeping loose material into its mouth with its flexible, broom-like teeth. In addition, it grasps and removes hard substrates with the aid of its special palate structure. It then transports sediment matter off the reef by defecating the ingested material outside the rocky zone of the reef. We analyzed 150 feces samples of six individuals, differentiating between (1) ingested by sweeping and (2) ingested by scraping, and compared their content with inorganic land-derived and marine sediments trapped at the feeding area. Projections based on fish densities, defecation rates, and quantities as well as composition of sediments collected by traps on the same reef site suggest that *C. striatus* removes at least 18% of the inorganic sediment sinking onto the reef crest. The eroded share in the exported matter is about 13%. This finding points to a hitherto not verified role of *C. striatus* as a reef sweeper and reef scraper, whereby the first function is by far dominating. [original abstract; wrzolek]

90204 <TITLE>The impact of seawater temperature on coral growth parameters of the colonial coral *Cladocora caespitosa* (Anthozoa, Scleractinia) in the eastern Adriatic sea.</TITLE>
90205 <SOURCE>Facies 58, 4: 477-491.</SOURCE>
90206 <ABSTRACT>The scleractinian coral *Cladocora caespitosa* deserves a special place among the major carbonate bioconstructors of the Mediterranean Sea. Annual coral skeleton growth, coral calcification, and skeleton density of the colonial coral *C. caespitosa* taken from 25 locations in the eastern Adriatic Sea were analyzed and compared with annual sea surface temperatures (SST). The growth rates of the coral *C. caespitosa* from the 25 stations in the Adriatic Sea ranged from 1.92 to 4.19 mm per year, with higher growth rates of the investigated corallites in the southern part of the Adriatic Sea. These growth rates are similar to those measured in other areas of the Mediterranean Sea. The correlation between coral growth and sea temperatures in the Adriatic sea is seen as follows: an X-radiograph analysis of coral growth in *C. caespitosa* colonies that are over 60 years old showed that higher growth rates of this coral coincided with a warmer period in the Mediterranean Sea. A positive significant correlation exists between corallite growth rates and SST and coral calcification and SST. A negative correlation exists between coral density and SST. Coral growth rates also showed a correlation with higher eutrophication caused by nearby fish farms, along with a greater depth of the investigated colonies and high bottom currents.</ABSTRACT>

90218 <SOURCE>Marine Geology 282: 149-159.</SOURCE>
90219 <ABSTRACT>This study explores a genetic link between modern Atlantic coral mounds and ancient, sponge-rich carbonate mudmounds based on Ca-carbonate authigenesis driven by induced-and-supported organomineralization (ISOM). The potential for ISOM in Atlantic coral mounds is tracked by peak patterns of fluorescent dissolved organic matter (FDOM) present in pore waters down to 3 m of sediment depth (Gamma mound, Beta mound, Pen Duick escarpment, offshore Morocco). The modern coral-rich mound system, which by itself appears diverse and with a variety of controlling factors, maintains an excellent potential to drive ISOM and to share a crucial process of early diagenesis with Phanerozoic sponge rich carbonate mudmounds.</ABSTRACT>

90256 <TITLE>Skeletal microstructure and stable isotope signature of three bathyal solitary cold-water corals from the Azores.</TITLE>
90257 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 373: 25-38.</SOURCE>
90258 <ABSTRACT>Skeletons of cold-water corals are potential geochemical archives that record oceanographic parameters, such as bottom water temperature in the deep sea. In this study, the three solitary scleractinian species, Caryophyllia cyathus, Desmophyllum cristagalli and Stenocyathus vermiformis, were sampled from upper bathyal 500m water depths in the southern Faial Channel (Azores archipelago). The stable carbon isotope (δ13C) and oxygen isotope (δ18O) compositions of the corals were analysed and related to their skeletal architecture. Background data, including data from high-resolution temperature logs and on the ambient seawater isotopic composition, were compared with δ18O-based temperature reconstructions to test the suitability of these cold-water corals as geochemical archives and to explore the role of vital effects on skeletal geochemistry. Although all of the corals experienced identical and near-stable salinities and temperatures, the stable isotopic signatures vary within and among species. Both δ13C and δ18O values fluctuate in relation to growth bandings and are therefore most likely dependent on calcification rates and associated kinetic vital effects. The studied specimens are 13C depleted with respect to equilibrium with ambient seawater, indicating significant uptake of respired CO₂ by their skeletons. Skeletal δ18O values vary by up to 3.6‰ among the growth bands of one of the coral specimens, translating into an unrealistic reconstructed temperature amplitude of ~16 °C. This contrasts with the minute intra-annual amplitude of the stable

temperature regime (annual mean 12.30 ± 0.25 °C). Nevertheless, 13C vs. 18O regression lines can be used to deduce ambient temperatures by applying the lines technique (Smith et al., 2000; Palaios 15: 25-32), which yields temperatures that coincide with the measured maximum temperature range in the case of D. cristagalli and for most C. cyathus samples, but deviate by 2.95 °C from the measured annual mean in the case of the S. vermiformis specimen.

90269 <TITLE>Constraining carbonate chemistry at a potential ocean acidification event (the Triassic-Jurassic boundary) using the presence of corals and coral reefs in the fossil record.</TITLE>

90270 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 350-352: 114-123.</SOURCE>

90271 <ABSTRACT>Ocean acidification associated with emplacement of the Central Atlantic Magmatic Province (CAMP) has been hypothesized as a kill mechanism for the end-Triassic mass extinction, but few direct proxies for ancient ocean acidity are available. This paper describes a new proxy that uses the presence of fossil corals and coral reefs to determine aragonite saturation state (Arag). Modern scleractinian corals struggle to biomineralize a skeleton below an Arag of 2 and modern shallow water coral reefs are typically only found in areas with source water of Arag >3, so when corals or coral reefs are preserved in the fossil record, these ocean saturation states can be inferred. Atmospheric pCO₂ reconstructions are combined with the coral Arag limitations to calculate the total dissolved inorganic carbon (DIC) in the Late Triassic ocean, which is a measure of the buffering capacity or ocean sensitivity to acidification. Once DIC is known, the severity of an acidification due to a carbon dioxide injection can be determined, for example the Triassic-Jurassic (T-J) event. Our results suggest that if Late Triassic DIC values were low to moderate (2000-3000 mol/kg), the T-J pCO₂ increases would have depressed saturation state to the point where coral biomineralization would have been extremely challenging (Arag < 2), resulting in the observed coral and coral reef gap in the fossil record. While the average pCO₂ elevations recorded in stomatal and pedogenic proxies are not sufficient to cause complete carbonate undersaturation, modeled scenarios for CAMP-related T-J pCO₂ increases (within error of pedogenic pCO₂ proxies) suggest that aragonite undersaturation is plausible and in extreme cases calcite undersaturation is achievable. Thus, a short but extreme acidification event could occur and would satisfactorily explain the significant extinction of calcareous organisms, the Early Hettangian coral gap, and the T-J carbonate crisis.</ABSTRACT>

- 90284 <ABSTRACT>A review of the book of Ernst & Königshof (2010) is given: The part of the book on the bryozoans (chapters "Taxonomic descriptions", "Systematic palaeontology", "Appendix" and plates) is very good. However, the part on stratigraphy and facies (chapters "Geological setting" and "Microfacies analysis") is unsatisfying. Among others, the given proof of a Late Givetian age is shown to be unsubstantiated. Fortunately, the [present] reviewer can demonstrate by the few informations on corals given by Ernst & Königshof (2010), that these fossils are probably Late Givetian in age. [abridged]</ABSTRACT>

- 90296 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 370: 260-270.</SOURCE>
- 90297 <ABSTRACT>A new ecological-severity ranking of the major Phanerozoic biodiversity crises is proposed in which the Capitanian crisis is ranked lesser than the Frasnian (Late Devonian) but greater than the Serpukhovian (end-Mississippian), and the Famennian (end-Devonian) crisis is ranked as equal in ecological impact to the Hirnantian (end-Ordovician). Two new decouplings between taxonomic severity and ecological severity are revealed in these analyses, the Capitanian and Famennian crises, in which the ecological impact of the biodiversity loss was markedly different from the magnitude of the biodiversity loss. These analyses also reveal that the "Great Devonian Interchange" (GDI) invasive-species event in the Givetian biodiversity crisis may provide an important palaeoecological analog for the study of present-day extinction and homogenization in ecosystems produced by modern invasive species.</ABSTRACT>

- 90310 <ABSTRACT>On the basis of a combined larger benthic foraminifera, nannofossil and strontium isotope dating programme we confidently

re-assign muddy carbonate deposits from the Lower Kinabatangan River Area of Borneo to the Oligocene rather than the Early Miocene. High-diversity, coral-rich (>50 species) deposits are here tightly constrained to predominately at, or just after, the Early to Late Oligocene boundary (Larger benthic foraminifera zone - Te1, Nannofossil zone - NP24, Sr isotope ages - 28.8-27.6 Ma). This new dating potentially pushes back the start of the Indo-west Pacific Centre of Marine Diversity, at least for corals, about 5 million years earlier than previous data indicated. Our new data supports maintaining separation of the muddy carbonates (previously defined as the Lower Kinabatangan Limestones: Haile & Wong, 1965) from nearby crystalline limestones of the Gomantong Limestone Formation dated here as Early Miocene (Larger benthic foraminifera zone - Te5/earliest Tf1, Sr isotope age - 21.0 Ma). This apparently punctuated development of shallow marine carbonates is seen at several locations in northern Borneo; an area underlain by oceanic crust and long dominated by very deep marine sedimentation (Hutchison, 2005). The opportunistic formation of clastic-influenced coastal and isolated biohermal carbonates is both an important palaeontological data point and a geological marker of changing basin settings. The new data on the first shallow marine deposits in a long established deep marine location, and evidence for unconformities, has important implications for the regional tectonic model, in an area of hydrocarbon exploration.

90322 <SOURCE>In: Earth and Life - International Year of Planet Earth 2012: 159-188.</SOURCE>

90323 <ABSTRACT>From research undertaken on brachiopods encrusted by auloporids at two intervals in the Frasnian (Beaulieu and Ferques Formations) of Boulonnais (France), we conclude that the most important factors influencing encrustation were usually (in decreasing order): size of the host, morphology, feeding currents, shell orientation in vivo and shell ornament. Shell structure (punctate or impunctate) seems not to have influenced the rate of encrustation. In the cases discussed, most but not all auloporids encrusted their hosts in vivo. The most favourable environments for development of both brachiopods and epibionts seem to have been hard bottoms and thin limestone beds alternating with argillaceous beds. The influence of environmental (sedimentologic) conditions is difficult to precisely specify in terms of the development of encrustation, but seems to have played an important role.</ABSTRACT>

90334 <TITLE>Gzhelian-Asselian Palaeoaplysina-microencruster reef community

- in the Taishaku and Akiyoshi limestones, SW Japan: Implications for Late Paleozoic reef evolution on mid-Panthalassan atolls. </TITLE>
- 90335 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 310, 3-4: 378-392.</SOURCE>
- 90336 <ABSTRACT>A Palaeoaplysina-microencruster reef community is recognized in the Gzhelian-Asselian interval of the Taishaku and Akiyoshi limestones in SW Japan, which represent accreted Panthalassan atoll carbonates. In a reef-core area of the atoll, the alga Palaeoaplysina acted as a framebuilder and was associated with various binders (e.g., Tubiphytes, Archaeolithoporella, cystoporate bryozoans, and microbialites) and sediment-bafflers such as fenestrate and cryptostomate bryozoans and phylloid algae. In a subtidal environment of the back-reef area, Palaeoaplysina and phylloid algae flourished as sediment-bafflers. A microbial community, including Tubiphytes and sessile foraminifers, was predominant in a very shallow, peritidal environment of the back-reef area. * Palaeoaplysina was distributed mainly along the northern margin of Pangea and is regarded as a boreal element. During Gzhelian-Asselian time, its distribution extended to the tropical or subtropical Panthalassa Ocean due to global cooling. On the Akiyoshi atolls, the Palaeoaplysina-microencruster community was succeeded by a sponge-microencruster community in the late Early Permian. The timing of this biotic turnover is similar to that of a change in climate from icehouse to greenhouse conditions, and coincides with superplume activity beneath the mid-Panthalassa Ocean.</ABSTRACT>

- 90347 <TITLE>Regional calibration of coral-based climate reconstructions from Palau, west Pacific warm Pool (WPWP).</TITLE>
- 90348 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 386: 308-320.</SOURCE>
- 90349 <ABSTRACT>Stable isotopic and trace element records from corals collected within the West Pacific Warm Pool (WPWP) are well suited to examine interannual to decadal climate variability associated with the El Niño-Southern Oscillation (ENSO) phenomenon. The most commonly used climate recorder in corals is δ180 (δ180CRL), a parameter subject to multiple regional and local environmental influences. Location-specific calibration of δ180CRL is a necessary first step for developing long-term paleoceanographic reconstructions. Here we present four new coral δ180 stratigraphies from the Republic of Palau (7.5°N 134.5°E), and compare our records with instrumental measurements for the period 1950-2008. We also compare our results with a previously published coral record from Palau. We employ a new sea surface salinity (SSS) product and validate its utility for coral-based paleoclimate calibrations. We not only examine differences among the records but also identify strong and regionally coherent environmental signals. We find that SSS variability is the dominant influence on δ180CRL in Palau, while sea surface temperature (SST) is of secondary importance. Our results show that time-averaging multiple δ180CRL records into a single composite series produce greater correlations with instrumental data and indices than individual stratigraphies alone. Our results are consistent with observations of a strengthening of the hydrological cycle in the WPWP region over the past 50 years, though the magnitudes of long term linear trends differ

among the different Palau [180CRL](#) records. Interannual and interdecadal variabilities between the Palau [180CRL](#) records are more consistent than the long term linear trends. Monthly Palauan [180CRL](#) anomalies capture strong El Nino events with high fidelity over the calibration period. This study provides constraints for future paleoenvironmental investigations in Palau using longer coral records.

90360 <TITLE>Sedimentary development of a continuous Middle Devonian to Mississippian section from the fore-reef fringe of the Brilon Reef Complex (Rheinisches Schiefergebirge, Germany).</TITLE>

90361 <SOURCE>Facies 59, 4: 969-990.</SOURCE>

90362 <ABSTRACT>The Brilon-reef complex is one of the biggest Devonian carbonate buildups (~80 km²) of the Rheinisches Schiefergebirge. The Burgberg section is located in the southeastern fore-reef area of the Brilon Reef Complex and exposes a succession of strata (117 m thick), which extends from the Middle Givetian (middle varcus conodont Zone) to the Viséan (bilineatus conodont Zone). Field and microfacies observations led to the definition of nine microfacies that are integrated into a sedimentary model divided into off-reef, intermediate fore-reef, and proximal fore-reef sedimentary domains (SD). The off-reef domain (SD1) is the most distal setting observed and is characterized by fine-grained sediments, dominated by pelagic biota and the local occurrence of gravity-flow deposits. The intermediate fore-reef (SD2) is characterized by a mixture of biota and sediments coming from both deeper-water and shallow-water sources and is influenced by storm and gravity-flow currents. In this domain, Renalcis moundlike structures developed locally. Finally, the proximal fore-reef (SD3) corresponds to the most proximal setting that is strongly influenced by gravity-flow currents derived from the Brilon Reef Complex. The temporal evolution of microfacies in the fore-reef setting of the Burgberg section show five main paleoenvironmental trends influenced by the onset, general development, and demise/drowning of the Brilon Reef Complex. Fore-reef to off-reef lithologies and their temporal changes are from the base to the top of the section: (U1) - finegrained sediments with large reef debris, corresponding to the initial development of the reef building upon submarine volcanoclastic deposits during the Middle Givetian (middle varcus Zone) and first export of reef debris in the fore-reef setting, (U2) - high increase of reef-derived material in the fore-reef area, corresponding to a significant progradation of the reef from the Middle Givetian to the Early Frasnian (maximum extension of the Brilon Reef Complex to the south, disparilis to the falsiovalis conodont biozones), (U3) - progressive decrease of shallow-water derived material and increase of fine-grained sediments and deep-water biota into the fore-reef setting, corresponding to the stepwise withdrawal of the reef influence, from the Middle to the Late Frasnian (jamieae conodont Zone), (U4) - development of a submarine rise characterized by nodular and cephalopod-bearing limestones extending from the Late Frasnian to the Late Famennian corresponding to the demise and drowning of the Brilon Reef Complex as a result of the Late Frasnian Kellwasser events (upper rhenana and triangularis conodont biozones), (U5) - significant

deepening of the Burgberg area starting in the Late Famennian, directly followed by an aggrading trend marked by pelagic shales overlying the nodular limestone deposits.</ABSTRACT>

90373 <TITLE>New data on the Silurian-Devonian palaeontology and biostratigraphy of Bolivia.</TITLE>

90374 <SOURCE>Bulletin of Geosciences 87, 2: 269-314.</SOURCE>

90375 <ABSTRACT>In order to precisely establish the bio- and chronostratigraphic position of several levels of the Silurian-Devonian succession of Bolivia, with respect to the International Time Scale, additional Silurian and Devonian localities belonging to the Eastern Cordillera and the Interandean Zone areas have been recently revised and sampled, both for macrofossils and palynomorphs. Specifically, the localities are Nunumayani, and Muruhuta from the late Silurian-early Devonian time interval. Correlations with other fossiliferous localities are discussed, namely Huacallani and Rumicorral. A new outcrop yielding Middle Devonian tabulate corals at Pisacavina is described, its faunal content is described, and compared with the historical coral collection. As a result, it appears clearly that the Silurian-Devonian Bolivian fauna needs a thorough revision, as well as the selection of stratigraphically significant macrofossils. Besides macrofossils, the analysis of palynomorph assemblages is significant in establishment of both intra-Bolivian and international correlations before any reliable biogeographic reconstruction is done. This paper records the first discovery of a plant of the genus *Protolepidodendron* from the Devonian of Bolivia. An ostracod assemblage from Pisacavina is described, illustrated, and discussed for the first time, it suggests an Early Devonian or an Eifelian age. Newly described taxa include the coral *Parastriatopora boliviana* sp. nov., and the chonetoid brachiopods *Sanjuanetes glemareci* sp. nov., and *Kentronetes giae* sp. nov.</ABSTRACT>

90386 <TITLE>Cobbles colonization pattern from a tsunami-affected coastal area (SW Thailand, Andaman Sea).</TITLE>

90387 <SOURCE>Facies 57, 1: 1-13.</SOURCE>

90388 <ABSTRACT>we studied the sclerobiont community associated with organogenic and lithic cobbles from soft bottoms in the Khao Lak coastal area (Andaman Sea) that was damaged by the 2004 tsunami. The 15 cobbles examined originate from grab and hand sampling carried out in the years 2006 and 2007 in the depth range of 4.6-15.2 m. A rich endo- and epibenthos was identified, mainly consisting of algae,

foraminifers, sponges, cnidarians, polychaetes, bryozoans and bivalves. Associations on each examined cobble show similarities in composition and structure being characterized by a few dominant groups. Differences were noted in the degree and pattern of colonization, distinguishing for each cobble an upward and a downward side at the time of sampling. The mean total coverage is 15.09% being higher on the upper sides (17.4%) compared to the lower sides (12.8%). Calcareous algae, bivalves and sponges prevail on upper sides, while bryozoans prevail on lower sides. The sclerobionts distribution allowed to infer the orientation of cobbles on the seafloor during colonization. Major colonization values, exceeding 30% coverage, were observed on organogenic cobbles located in the proximity of reefs or collected from below 12 m of water depth. Conversely, cobbles from the shallowest stations result poorly colonized, independently of their composition. The water turbidity and wave motion as a possible cause of the observed distributions were discussed. The Khao Lak cobble community seems to be largely unaffected by the tsunami event, as suggested by the estimated biodiversity, abundance and coverage of sclerobionts.

90399 <TITLE>Symbiotic association of a pyrgomatid barnacle with a coral from a volcanic middle Miocene shoreline (Porto Santo, Madeira Archipelago, Portugal).</TITLE>
90400 <SOURCE>Palaeontology 55, 1: 173-182.</SOURCE>
90401 <ABSTRACT>The bioclaustration of the pyrgomatid barnacle *Ceratoconcha* aff. *costata* within the carbonate skeleton of a colonial hermatypical coral (*Tarbellastrea reussiana*) is described from a middle Miocene basaltic rocky palaeoshore on a small north-eastern Atlantic islet of Porto Santo (Madeira Archipelago, Portugal). The resulting structure is named as a new trace fossil *Imbutichnus* igen. nov., characterized by a small, funnel-like cavity, a circular to oval cross-section, with a nearly cylindrical shape in the upper part and a conical shape towards the base. *Imbutichnus costatum* isp. nov. is defined as a bioclaustration structure produced by the overgrowth of a pyrgomatid barnacle by a coral. From an ethologic point of view, *Imbutichnus* is attributed to the *Impedichnia* category. In terms of palaeoecology, it is interpreted as the result of a parasitic relationship. This is also the oldest record of pyrgomatid barnacles in the eastern Atlantic and clearly demonstrates that the Miocene palaeogeographic range of *Ceratoconcha* was much wider than previously assumed.</ABSTRACT>

90412 <TITLE>A parautochthonous shallow marine fauna from the Late Burdigalian (early Ottnangian) of Gurlarn (Lower Bavaria, SE Germany): Macrofaunal inventory and paleoecology.</TITLE>

- 90413 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Abhandlungen 254, 1/2: 63-103.</SOURCE>
- 90414 <ABSTRACT>This paper describes and illustrates a diverse parautochthonous macrofauna from a single Upper Burdigalian (lower Ottnangian) horizon at Gurlarn in Lower Bavaria (SE Germany). In total, 80 different taxa are recorded in specific or open nomenclature; some 50% of these taxa are bryozoans, followed by bivalves (16 taxa), cirripedes (7 taxa), echinoderms, corals (5 taxa each), brachiopods, fish (4 taxa each), serpulids, and gastropods (3 taxa each). The presence of additional organisms was documented by actualistic comparison based on indirect evidence such as drillholes, bite marks, and specialized growth forms of bryozoan colonies. Analysis of aut- and synecological indicators suggests that the fauna thrived in a near-shore shallow marine setting at a water depth of 5-20 m. Based on particular faunal elements and overall faunal composition we hypothesize that the environment is characterized by three distinct but interfingering habitats, i.e. (1) rocky slopes and boulders, (2) seagrass meadows, and (3) bryozoan meadows. Because similar, albeit less well-preserved, faunas occur at several localities along the northern coast of the early Ottnangian Molasse Sea, the parautochthonous assemblage from Gurlarn provides an excellent example for the structure of these typical biota.</ABSTRACT>

- 90425 <TITLE>Upper Triassic (Carnian) reef biota from the Sambosan Accretionary Complex, Kyushu, Japan.</TITLE>
- 90426 <SOURCE>Facies 58, 4: 671-684.</SOURCE>
- 90427 <ABSTRACT>Calcified sponges, algae, and reef problematica are abundant yet poorly known from the Triassic of Japan. They are abundant in shallow-water carbonate, redeposited blocks of the Sambosan Accretionary Complex, Konose Group, and southern Kyushu. Based on study of thin-sections from reef limestone exposed along the Kuma River, some important organisms and reef microfacies are described, which seem typical of Upper Triassic reef complexes. The most abundant reef organisms are hypercalcified sponges, including sphinctozoans, inozoans and chaetetids, followed by cyanophycean algae (including "Tubiphytes"-like organisms), and solenoporacean red algae. Loose sponge spicules in one thin-section also indicate the occurrence of rare hexactinellid sponges. Chambered demosponges described from the Konose carbonate rocks include Solenolmia manon manon (Münster), Colospongia sp., Jablonskyia andrusovi (Jablonsky), several unidentified chambered sponges as well as the inozoid Permocorynella sp. 1 and Permocorynella sp. 2. Also present are chaetetid sponges and solenoporacean red algae belonging to Parachaetetes cassianus (Flügel) and Parachaetetes? sp. or Solenopora? sp. Especially abundant in thin-sections are cyanophyceans and "Tubiphytes"-like organisms. Among the organisms is Cladogirvanella Ott and Hedstroemia sp. The composition of the biota and presence of typical problematic organisms increases our knowledge of shallow-water Upper Triassic carbonate rocks in a remote setting in western Panthalassa. The composition of the biota indicates a mostly Carnian age. Most comparable organisms are known from both the northeastern and southern Tethys.</ABSTRACT>

90438 <TITLE>Palaeobiogeographical constraints on the distribution of foraminifers and rugose corals in the Carboniferous Tindouf Basin, South Morocco.</TITLE>
90439 <SOURCE>Journal of Paleogeography 2, 1: 1-18.</SOURCE>
90440 <ABSTRACT>The northern flank of the Tindouf Syncline in southern Morocco exhibits a continuous, well exposed Carboniferous succession with limestones of late Asbian to early Bashkirian age containing rich and diverse foraminiferal and rugose coral assemblages. Analysis of these assemblages provides new data on the relatively poorly known Saharan basins. * The palaeobiogeographical relationship of the Tindouf Basin with other Palaeotethyan basins is complex. Although there is a predominance of cosmopolitan taxa for the Palaeotethys, it is recognized that there was an influence of basins from NW Europe, such as the UK and Ireland. Some taxa are recorded in both NW Europe and Tindouf without any characteristic contributions from intermediate basins in northern Morocco. The neighbouring Bechar Basin in Algeria presents distinct assemblages. The bulk of the data analyzed suggest that this sector of the western Palaeotethys can be subdivided into four palaeobiogeographical subprovinces: the Atlantic subprovince (UK, Ireland, N. France and Belgium), the Mediterranean subprovince (Pyrenees, Montagne Noire, Betic Cordillera, Rif - N. Morocco, and Balearic Islands), and the Saharan subprovince (Bechar, Reganne, Ahnet-Mouydir and Tindouf). In between, mobile belts of mixed faunal assemblage characteristics are observed (e.g., SW Spain and Central Meseta) forming the west peri-Gondwanan subprovince. ** Analysis of the Tindouf Basin faunas shows that, as in other Saharan basins, there is a high diversity and abundance of foraminiferal taxa, with a higher proportion of survivors and longer stratigraphic ranges, features also mirrored by rugose corals. This emphasizes the longevity of the carbonate platform in a tropical setting, where periodic transgressions introduced new assemblages, and oceanic currents are interpreted as one of the main controlling factors for the distribution of the taxa in these subprovinces. Moreover, not only were water temperatures on the platform higher, but also tectonic stability greater. It is considered that the effects of the first phases of the Gondwanan glaciation were minimal on the Tindouf faunas.</ABSTRACT>

90451 <TITLE>Mentors: the generation 1935-1985.</TITLE>
90452 <SOURCE>Geologica Belgica 15, 4: 204-208.</SOURCE>
90453 <ABSTRACT>The lives and scientific contributions of five eminent academic geologists and paleontologists, James Alloiteau (Museum National d'Histoire Naturelle, Paris, France), Dorothy Hill (University of Queensland, Australia), Marius Lecompte (University of Louvain, Belgium), Masao Minato (Hokkaido University, Sapporo, Japan), and Maria Różkowska (Adam Mickiewicz University, Poland) are briefly

summarized here. Each of these paleontologists made major contributions to the study of fossil corals and/or sponges, and each overcame considerable difficulties and disruptions in their lives to excel as mentors to us. All showed remarkable determination and love for paleontological research, and inspired their students and colleagues to understand details of structure and systematic positions of fossil corals and sponges. Each of these individual mentors was the subject of a presentation by a former student at the 11th International Symposium on Fossil Corals and Sponges in Liege, Belgium, thus, somewhat broader coverage of each is provided in the abstracts volume of the meeting.

90464 <TITLE>Sequence development on a sediment-starved, low accommodation epeiric carbonate ramp: Silurian Wabash Platform, USA mid-continent during icehouse to greenhouse transition.</TITLE>

90465 <SOURCE>Sedimentary Geology 224: 84-115.</SOURCE>

90466 <ABSTRACT>Twelve cored wells through the Silurian section of the Wabash Platform, Indiana, U.S.A., and 2 non-cored basinal wells with cuttings, were studied to define the sequence stratigraphy of a sediment-starved ramp within a low-latitude epeiric sea during the latest Ordovician icehouse to Silurian greenhouse transition. The Wabash Platform (approximately 200,000 km² area) was bounded to the north by the Michigan Basin, to the east by the Appalachian foreland basin, and passed to the southwest into the Vincennes Basin, which was open to the ocean. Facies developed include: platform-fringing buildups (stromatolitic wackestone core, stromatoporoid skeletal wackestone caps and crinoidal rudstone/packstone flank facies), and non-buildup crinoid grainstone-packstone sheets (shoals), skeletal wackestone (variably cherty, between fair weather and storm wave base, deep lagoon and deep ramp) and carbonate mudstone (clean to argillaceous, sub-storm wave base, deep lagoon and deep ramp/basin). The eleven sequences, 2 m to 30 m thick and 1 to 4 m.y. durations (average ~ 2.5 m.y.), generally can be correlated to global sea-level cycles. The lower three sequences are disconformity-bounded (reflecting moderate ice sheets) but the others are relatively conformable. The most easily mapped regional surfaces are the transgressive surfaces, because the correlative conformities are cryptic. The wide well spacing prevented mapping of lowstand system tracts. The transgressive system tracts are upward-deepening, upward-fining carbonate units, that become more argillaceous and silty upward. The highstand system tracts are upward-coarsening carbonate mudstone to wackestone-packstone and rare grainstone. Barrier bank complexes and isolated buildups aggraded during deposition of the upper 4 sequences to form a discontinuous raised rim (~ 40 m relief) to the ramp while the interior of the platform remained sediment starved. Subsidence rates in the basin were very low (0.6 to 1.2 cm/k.y.), but the low platform accumulation rates (0.2 cm/k.y. to 0.8 cm/k.y.) prevented the seafloor from building to sea level in all but the lower three sequences and later over barrier banks (accumulation rates 2 cm/k.y.). Parasequence development in high-accommodation settings elsewhere in the Silurian in North America records transition from moderate ice-sheets to an ice-free world. This is weakly expressed on the Wabash Platform due to the dominantly deeper subtidal setting. The remarkably low sedimentation rates resulted from the epeiric sea being

- isolated from the open ocean, and they likely are typical of the large epeiric seas of the Paleozoic.</ABSTRACT>

- 90490 <TITLE>Replacement name for Tetradium Dana, 1846.</TITLE>
- 90491 <SOURCE>Journal of Paleontology 85, 4: 802-803.</SOURCE>
- 90492 <ABSTRACT>Tetradium Dana, 1846 (type species: Tetradium fibratum Safford, 1856), a common Middle and Upper Ordovician fossil, is a calcareous filamentous florideophyte alga (Phylum Rhodophyta) (Steele-Petrovich, 2009a, 2009b), and not a tabulate coral or a chaetetid sponge, as traditionally classified. This makes it a later homonym of Tetradium Loureiro, 1790 (see Farr et al., 1979), a Recent tree. It will be substituted by Prismostylus Okulitch 1935. A new specific classification of the genus Prismostylus Okulitch (and possibly other closely related genera) would have to be based probably on tube morphology. Family and Order names that are based on the illegitimate genus Tetradium (i.e., Tetradiidae Nicholson, 1879 and Tetradiida Okulitch, 1936, respectively), which would normally become Tetradiaceae and Tetradiales in botanical tradition, must be replaced also (ICBN, Rec. 16B, Art. 18.3). Therefore, the replacement names selected here are Family Prismostylaceae and Order Prismostylales. The type species is Prismostylus columnaris (Hall), 1847, as designated by Okulitch (1935) when the genus was defined.</ABSTRACT>

- 90503 <TITLE>Distribution of three key Early Permian fossil groups in western USA and northern Mexico and their relevance to interpretation of paleotectonic features along the southwestern margin of Laurentia.</TITLE>
- 90504 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 288, 1-4: 103-107.</SOURCE>

- 90505 <ABSTRACT>Three species groups, including two groups of corals and one of fusulinids, delineate the zone of favorable marine environments for these animals along the shelves bordering southwestern Laurentia during the Cisuralian (Early Permian). The three species groups are: the coral Protowentzelella group of late Asselian to early Sakmarian age, the fusulinid Eoparafusulina linearis group of late Sakmarian age, and the coral Pararachnastraea illipahensis group of late Artinskian to Kungurian age. Occurrences of these three species groups clearly outline most of the major paleotectonic features that were present along the southwestern margin of the Laurentian shelf at that time. The paucity of data in Mexico, however, leaves open the question of large-scale displacement on the Mojave-Sonora megashear, a feature proposed to cut across northern Mexico and southwestern USA, although the data presented here could be construed to suggest lack of significant displacement in post-Pennsylvanian time.</ABSTRACT>

- 90516 <TITLE>Blackened bioclasts and bituminous impregnations in the Koneprusy Limestone (Lower Devonian), the Barrandian area, Czech Republic: implications for basin analysis.</TITLE>
- 90517 <SOURCE>Facies 58: 759-777.</SOURCE>
- 90518 <ABSTRACT>Carbonate reef talus facies of the Koneprusy Limestone (Pragian, Lower Devonian, Barrandian) locally exhibit widespread impregnation by organic matter resulting in a partial to complete blackening of the limestones. Two contrasting types of impregnation are recognized: blackening of individual carbonate fossils and bioclastic layers within the limestone originated very early during diagenesis. The blackening is due to finely dispersed organic matter and possibly some iron sulphides and clay minerals that selectively adhered to the outer layers of corals, bryozoans, and crinoid fragments, leaving other fossils unaltered. These darkened fossils are similar to black pebbles - i.e., reworked, dark to black limestone clasts and bioclasts that are known to occur exclusively in shallow-water zones of both ancient and modern carbonates. The alteration of fossil fragments may have taken place in very shallow-water environments, possibly those of saline and reducing back-reef lagoons or supratidal/intertidal zones, with organic matter being derived from decayed algae and microbes, or early vascular terrestrial plant material. Following the coloration, the blackened fossils were removed from their original position by waves or storms and transported into relatively deeper-water reef slope settings to form graded, “salt-and-pepper”-colored bioclastic beds. The presence of blackened fossils in the carbonate succession may point to episodic emergence and indicates a vanished vegetated siliciclastic hinterland that may once have existed to the west or south from the present-day erosive edge of the Barrandian Devonian strata. Subvertical veins cutting the Koneprusy Limestone and filled with black solid bitumen and blackened calcite resulted from a subsequent but substantially later diagenetic event, which is a testament of aqueous and petroleum fluid migration through the succession during deeper burial. Microthermometric characteristics of the aqueous inclusions embedded in vein calcite indicate that the veins were precipitated by brines of low to moderate salinity (0.5-9.5 wt% NaCl equiv.) with temperatures in the range of 87-116 °C. The bitumen in the veins is epi-impsonite (Rr = 0.70-1.90%), which is interpreted as degraded

petroleum residuum that experienced thermal alteration at around 120 °C. The AFT modeling combined with fluid inclusion microthermometry and wider geological considerations indicate that the veins originated during the Variscan orogeny, most probably upon deep burial of the Lower Paleozoic strata in Carboniferous time.

90529 <TITLE>An early Campanian rocky shore at Ivö Klack, southern Sweden.</TITLE>

90530 <SOURCE>Cretaceous Research 31, 6: 567-576.</SOURCE>

90531 <ABSTRACT>well-exposed, ancient rocky shores are rare and the associated shelly faunas are normally strongly worn and fragmented due to erosion during both sea-level rise and fall. An early Campanian rocky shore with a rich fauna is preserved at Ivö Klack in the Kristianstad Basin, southern Sweden. Ivö Klack is situated on the small, hilly island of Ivö situated in lake Ivösjön with a lake level about 6 m above present-day sea level. The rocky shore was formed during a major late early Campanian transgression caused by a sea-level rise up to about 100m above present sea level. An archipelago was formed along the northern basin margin during the transgression with numerous small islands and peninsulas. The steep palaeo-coast at Ivö Klack consists of gneiss overlain in the lower part by more than 30m of kaolin in places containing large boulders of gneiss with a kaolinized outer crust. The kaolin wedges out upslope and is absent above 30-35 m above lake level. The kaolin is overlain by up to 5m of muddy quartz sand with highly angular grains, representing a residue of the kaolin formed during transgressive wave and current reworking. The steep gneiss coast was rapidly transgressed by the sea in the latest early Campanian and at least 25m of overlapping coarse-grained skeletal sand, gravel and whole fossils were deposited on the clean gneiss surface during the Belemnelloamax mammilatus belemnite biozone. Large boulders of gneiss are common in the carbonates and formed distinct boulder beds at some levels but these are now quarried away. The top 6m of the preserved carbonate succession are free of boulders. The rocky surface is fairly even on a large scale, but highly irregular in detail with numerous metre-sized hummocks and boulders formed during terrestrial weathering and kaolinization. The lowest part of the shore is developed as a bench, topped by a sub-horizontal irregular platform, 20-30 m wide, with large hummocks and rounded boulders. The platform passes upwards into a steep boulder-strewn slope. A well-developed glauconitized hardground with Thalassinoides burrows and several incipient hardgrounds occur in the carbonates draping the bench and lower part of the platform. They dip gently outwards and probably represent a kind of beach rock. A highly diverse benthic fauna with more than 200 shell-bearing species lived between, below and on the hummocks and boulders. It comprises bivalves, brachiopods, polychaetes, gastropods, echinoids, asteroids, bryozoans and is dominated by large oysters and includes the northernmost Late Cretaceous rudists and hermatypic corals. The remaining benthic invertebrate groups are represented by only a few species each. The non-benthic invertebrate fauna comprises four belemnite species and one rare ammonite species. The lower Campanian carbonates of the small basin have yielded an unusually diverse vertebrate fauna totalling more than 60 species, including mosasaurs, plesiosaurs, crocodiles, turtles, birds, and as many as 44 species of sharks and rays. Ivö Klack thus provides

information on virtually all trophic levels in the rocky shore ecosystem and represents the most diverse rocky shore fauna known from the geological record. This paper aims at providing the framework for a series of papers on the palaeoecology of the main benthic faunal groups.

90543 <SOURCE>Abhandlungen der Geologischen Bundesanstalt 65: 135-154.</SOURCE>

90544 <ABSTRACT>Grey marls of the Lower Gosau-Subgroup exposed in a left tributary of the Kohlbachgraben north of St. Gilgen have yielded foraminifers, calcareous nannofossils and palynomorphs as well as poorly preserved plant remains. The microfossils indicate a Turonian or Turonian/Coniacian boundary age. On top of the grey marls a several meters thick succession of marly limestone and marl follows, whose fossil fauna is dominated by radiolitid rudists. Grey marls sampled in two exposures situated near the long-known fossil locality "Billroth" yielded poorly preserved microfossils as well as a moderately diverse colonial coral and rudist assemblage, indicating a Turonian age. The most important findings of palynomorphs and macrofossils are briefly described and figured.</ABSTRACT>

90581 <TITLE>Diverse early endobiotic coral symbiont assemblage from the Katian (Late Ordovician) of Baltica.</TITLE>

90582 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 321-322: 137-141.</SOURCE>

90583 <ABSTRACT>A diverse early endobiotic coral symbiont assemblage has been detected within heliolitid tabulate corals of Katian age from northwestern Estonia. This assemblage indicates that the earliest endobiotic coral symbiont communities were not restricted to North America. The symbiotic endobiont assemblage comprises abundant *Cornulites* aff. *celatus* and rare *Conchicolites hosholmensis* and *Chaetosalpinx* sp. The cornulitids are the earliest known symbiotic endobionts of this group. The symbiotic endobionts presumably occurred in certain hosts only and preferred *Protoheliolites dubius* over *Propora speciosa*. This record indicates that early endobiotic cornulitids were more diverse than previously thought and appeared in large numbers in the Katian. It is possible that the appearance of abundant skeletal symbiotic coral endobionts may coincide with the Global Ordovician Biodiversification Event, supporting the hypothesis of escape from increased predation.</ABSTRACT>

90594 <TITLE>Endosymbiotic *Cornulites* in the Sheinwoodian (Early Silurian) stromatoporoids of Saaremaa, Estonia.</TITLE>

90595 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie Abhandlungen 257, 1: 13-22.</SOURCE>

90596 <ABSTRACT>The new endosymbiotic cornulitid *Cornulites stromatoporoides* n. sp. is described here from the Sheinwoodian stromatoporoids of Saaremaa, Estonia. This new species represents the earliest record of cornulitid endosymbiosis, probably reflecting increased pressure by boring and durophagous predators on worms with mineral tubes in the Silurian. In lower Sheinwoodian open shelf marls, 30% of stromatoporoids are infested by *C. stromatoporoides* n. sp., 77 % of stromatoporoids in upper Sheinwoodian shoal limestones also had this endosymbiotic relationship. *C. stromatoporoides* n. sp. has thus far only been found as an endosymbiont in stromatoporoids. There is a range of one to six, averaging 2.4, endosymbiotic *C. stromatoporoides* n. sp. specimens (syn vivo) per infested stromatoporoid in the lower Sheinwoodian. Large stromatoporoids contain more *Cornulites* endosymbionts than smaller stromatoporoids.</ABSTRACT>

90607 <TITLE>Phosphatic intraclasts in shallow-water hemipelagic strata: a source of palaeoecological, taphonomic and biostratigraphic data (Upper Turonian, Bohemian Cretaceous Basin).</TITLE>
90608 <SOURCE>Cretaceous Research 30: 204-222.</SOURCE>
90609 <ABSTRACT>A prominent phosphatic lag exposed in the Upper Turonian hemipelagic strata near Byckovice, Bohemian Cretaceous Basin, yields an enormous accumulation of diversified, phosphatized and unphosphatized fauna. Taphonomic, palaeoecological and sedimentological data suggest that the phosphatic lag records a complex history of burial, mineralization and exhumation of sediment and fossils. Three main stages can be distinguished in the formation of the lag: (1) deposition of a hemipelagic marlstone or limestone inhabited by a diversified, softground fauna, then (2) intense phosphatization, winnowing of unconsolidated sediment and exhumation of the phosphates due to a combined effect of elevated bottom shear stress and bioturbation, and (3) resumption of hemipelagic deposition and establishment of a new assemblage dominated by sponges attaching to the exhumed phosphatic intraclasts. The occurrence of sponges inhabiting phosphatic intraclasts is unique in both fossil and recent ecosystems. One of these sponges, a poorly known hexactinellid *Laocoetis cretacea* (Rauff) is therefore described in detail. Biostratigraphic data suggest that the lag represents the uppermost subprionocyclus neptuni Zone and lowermost *Mytiloides scupini* Zone. Well-log correlation with coeval, orbitally tuned strata further suggests that the absolute duration approximated 350 kyr.</ABSTRACT>

90620 <TITLE>Bioerosion in an equatorial Middle Jurassic coral-sponge reef community (Callovia, Matmor Formation, southern Israel).</TITLE>
90621 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 289, 1-4: 93-101.</SOURCE>
90622 <ABSTRACT>The Matmor Formation (Middle Jurassic, Callovian, 165-161 mya) in southern Israel contains abundant coral-sponge patch reefs and large crinoids which have been extensively bioeroded by bivalves, worms, barnacles, phoronids, and others producing eight ichnospecies. It is significant for the evolutionary history of bioerosion because this is the first equatorial Middle Jurassic boring ichnofauna to be documented. When compared to contemporaneous ichnofaunas, this assemblage is of average diversity and abundance but has only rare sponge borings and contains abundant specimens of *Oichnus paraboloides* as shallow pits on crinoid stems. The Matmor Formation surprisingly lacks carbonate hardgrounds, which are otherwise abundant in subtropical and temperate equivalents.</ABSTRACT>

90633 <TITLE>High-precision U-series ages of transported coral blocks on Heron Reef (southern Great Barrier Reef) and storm activity during the past century.</TITLE>
90634 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 337-338: 23-36.</SOURCE>
90635 <ABSTRACT>Transported coral blocks scattered on reef flats have previously been identified as useful proxies for past storm occurrences. High-precision TIMS U-series dating and detailed field observations of 110 coral samples collected from 102 individual transported coral colonies (coral blocks) and 4 transported sections of reef matrix (reef blocks) from the northern side of Heron Reef (southern Great Barrier Reef) indicate that: (1) the youngest age of corals attached to reef blocks may represent the age of possible past storm occurrence, providing a proxy for historical storm reconstruction; (2) most ages of dated storm-transported coral and reef blocks match well relatively with known cyclone and storm events, further supporting that they are good indicators of past storm events; and (3) age distribution and relative probability frequency analysis of the dated coral and reef blocks suggest that there have been eight broad periods of storm occurrence since 1900 AD (1904-1909, 1914-1916, 1935-1941, 1945-1960, 1965-1967, 1976-1977, 1983-1988 and 2001-2007), roughly showing decadal variations. The coral-based storm reconstruction therefore extended the database of past storm occurrences around Heron Reef area. These findings suggest that coral reefs in the southern Great Barrier Reef are frequently influenced by periods of high storm activity, and show strong resilience to natural disturbances over the past century. Additionally, our results show for the first time that the blue skeletal coral *Heliopora coerulea* (order: Helioporaceae) has U concentrations of only 0.12 to 0.30 ppm, ~5-10% that of common reef building corals with white skeletons (Order: Scleractinia), which may be a unique chemical signature of the only living species of the Helioporidae family.</ABSTRACT>

90659 <TITLE>The evolution of mid Paleocene-early Eocene coral communities: How to survive during rapid global warming.</TITLE>

90660 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 317-318: 48-65.</SOURCE>

90661 <ABSTRACT>Today, diverse communities of zooxanthellate corals thrive, but do not build reef, under a wide range of environmental conditions. In these settings they inhabit natural bottom communities, sometimes forming patch-reefs, coral carpets and knobs. Episodes in the fossil record, characterized by limited coral-reef development but widespread occurrence of coral-bearing carbonates, may represent the fossil analogs of these non-reef building, zooxanthellate coral communities. If so, the study of these corals could have valuable implications for paleoenvironmental reconstructions. Here we focus on the evolution of early Paleogene corals as a fossil example of coral communities mainly composed by zooxanthellate corals (or likely zooxanthellate), commonly occurring within carbonate biofacies and with relatively high diversity but with a limited bioconstructional potential as testified by the reduced record of coral reefs. We correlate changes of bioconstructional potential and community compositions of these fossil corals with the main ecological / environmental conditions at that time. The early Paleogene greenhouse climate was characterized by relatively short pulses of warming with the most prominent occurring at the Paleocene - Eocene boundary (PETM event), associated with high weathering rates, nutrient fluxes, and pCO₂ levels. A synthesis of coral occurrences integrated with our data from the Adriatic Carbonate Platform (SW Slovenia) and the Minervois region (SW France), provides evidence for temporal changes in the reef-building capacity of corals associated with a shift in community composition toward forms adapted to tolerate deteriorating sea-water conditions. During the middle Paleocene coral-algal patch reefs and barrier reefs occurred from shallow-water settings, locally with reef-crest structures. A first shift can be traced from middle Paleocene to late Paleocene, with small coral-algal patch reefs and coral-bearing mounds development in shallow to intermediate water depths. In these mounds corals were highly subordinated as bioconstructors to other groups tolerant to higher levels of trophic resources (calcareous red algae, encrusting foraminifera, microbes, and sponges). A second shift occurred at the onset of the early Eocene with a further reduction of coral framework-building capacity. These coral communities mainly formed knobs in shallow-water, turbid settings associated with abundant foraminiferal deposits. We suggest that environmental conditions other than high temperature determined a combination of interrelated stressors that limited the coral-reef construction. A continuous enhancement of sediment load / nutrients combined with geochemical changes of ocean waters likely displaced corals as the main bioconstructors during the late Paleocene-early Eocene times.

Nonetheless, these conditions did not affect the capacity of some corals to colonize the substrate, maintain biodiversity, and act as locally important carbonate-sediment producers, suggesting broad environmental tolerance limits of various species of corals. The implications of this study include clues as to how both ancient and modern zooxanthellate corals could respond to changing climate.

90672 <TITLE>Is absence of proof a proof of absence? Comments on commensalism.</TITLE>

90673 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 302: 484-488.</SOURCE>

90674 <ABSTRACT>Commensalism in the narrow sense can be understood as an interaction strictly neutral for one organism and positive for the other. Neutral interaction is the absence of interaction and as such it cannot be proven (the proof of absence cannot be made) and consequently it can be regarded as a concept unfit for empirical science. In the broad sense it is often understood as a weak (positive or negative) interaction on one hand and positive on the other. This approach also seems imperfect, as weak interactions should be regarded rather as mutualism or parasitism, respectively. The borders between interactions (commensalism/parasitism and commensalism / mutualism) are difficult to define, hence commensalism should rather be considered as a theoretical interval within the continuum of interactions. Detection of commensalism in recent associations is rather difficult, while in the fossil record it seems impossible. Commensalism as a null hypothesis in paleoecology cannot be retained, as the possibility of making a type II error is very high. The terms "paroecia" and "endoecia" seem to be more useful to use in cases when a particular ecological relationship is difficult to prove.</ABSTRACT>

90685 <TITLE>Evidence of photosymbiosis in Palaeozoic tabulate corals.</TITLE>

90686 <SOURCE>Proceedings Royal Society B 22 281: 1775 20132663. doi: 10.1098/rspb.2013.2633 (online since December 2013)</SOURCE>

90687 <ABSTRACT>Coral reefs form the most diverse of all marine ecosystems on the Earth. Corals are among their main components and owe their bioconstructing abilities to a symbiosis with algae (Symbiodinium). The coral-algae symbiosis had been traced back to the Triassic (ca 240 Ma). Modern reef-building corals (Scleractinia) appeared after the Permian-Triassic crisis; in the Palaeozoic, some of the main reef constructors were extinct tabulate corals. The calcium carbonate secreted by extant photosymbiotic corals bears characteristic isotope (C and O) signatures. The analysis of tabulate corals belonging to four orders (Favositida, Heliolitida, Syringoporida and Auloporida) from Silurian to Permian strata of Europe and Africa shows these

characteristic carbon and oxygen stable isotope signatures. The $\delta^{18}\text{O}$; $\delta^{13}\text{C}$ ratios in recent photosymbiotic scleractinians are very similar to those of Palaeozoic tabulates, thus providing strong evidence of such symbioses as early as the Middle Silurian (ca 430 Ma). Corals in Palaeozoic reefs used the same cellular mechanisms for carbonate secretion as recent reefs, and thus contributed to reef formation. [electronic supplementary material at <http://dx.doi.org/10.1098/rspb.2013.2663>] </ABSTRACT>
