7 <TITLE>European Fossil Reef Models.</TITLE>
8 <SOURCE>SEPM Special Publications 30: 546 pp.</SOURCE>
9 <ABSTRACT>[excerpt from a book review by J.A. Babcock]: &#34;There is
  another jewel in the SEPM&#039;s crown of publications. European Fossil
  Reef Models is a multifaceted gem of information about European
  carbonate buildups and about the state of the art of European reef
  studies, all in English. Diversity is the key word here. Contained
  within 546 pages (18 papers) is an entire spectrum of scientific
  approaches and writing styles. Contributions range in length from 8
  pages (&#34;Upper Triassic coral bioherms&#34;; Yugoslavia, by Car and
  others) to 70 pages (&#34;Upper Triassic reef paleoecology&#34;; by
  Flügel). There are very specific papers (&#34;Pore types in a Paleocene
  reef&#34;; Yugoslavia, by Babic and Zypanic), and there are general
  summaries (&#34;Process approach to reef recognition&#34;; by Longmann;
  and &#34;European Devonian reefs&#34;; by Burchette). Although there is
  a bias towards Upper Triassic paleoecologic studies (five
  contributions, most of them by Erik Flügel and his students), there is
  good coverage of other parts of the geologic column as well. The
  Silurian, Devonian, Paleocene, Oligocene, and Recent are all
  represented by single papers, two papers concentrate on the Upper
  Jurassic, and both the Permian and the Cretaceous are covered by three
  papers each. If you are searching for comprehensive review papers on
  &#34;European reefs&#34;; then this volume will help. The contributions
  by Burchette (Devonian reefs), by Flügel (Upper Triassic reefs) and by
  Frost (Oligocene reefs) are all recommended. Silurian bioherms and
  biostromes are the subject of the contribution by Riding. His excellent
  paper is well-balanced between careful observations and
  interpretations. Car and others (Triassic bioherms) have written one of
  the best short papers. The contribution by Piller on the famous
  Steinplatte complex of northern Austria presents new sedimentologic
  interpretations in a well-documented manner. The monumental works by
  both Flügel (Upper Triassic reefs) and Frost (Oligocene reefs) will be
  standards for years to come.&#34;</ABSTRACT>

46 <TITLE>Parallel evolution in European rugose corals of the genus Lonsdaleia McCoy, 1849 (Lower Carboniferous).</TITLE>
47 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de Belgique, Sciences de la Terre 73: 109-135.</SOURCE>
48 <ABSTRACT>Two lineages, both leading to cerioid and subcerioid species, can be discerned in the evolution of the genus Lonsdaleia McCoy, 1849: L. (Lonsdaleia) duplicata (Martin, 1809) gave rise to the subgenus Actinocyathus D'Orbigny, 1849 (considered here as a subgenus of Lonsdaleia) at the beginning of the latest Viséan in northern Europe, and L. (Lonsdaleia) redondensis sp.nov. or a related species possibly evolved into L. (Serraphyllum) subgen. nov. near the Viséan/Serpukhovian transition in South France. Three new species of the genus Lonsdaleia are described from the uppermost Viséan and Serpukhovian of the Montagne Noire (South France), including two new species assigned to the subgenus L. (Serraphyllum). Two species of the subgenus L. (Actinocyathus) are redescribed from the Serpukhovian of the Moscow Basin. Parallel evolution in Actinocyathus and Serraphyllum during the Serpukhovian is discussed.</ABSTRACT>

59 <TITLE>Sponges from the Epicontinental Triassic of Europe.</TITLE>
60 <SOURCE>In Hagdorn H. & Seilacher A. (eds) - Muschelkalk; Schöntaler Symposium 1991: 235-244.</SOURCE>
61 <ABSTRACT>The knowledge about sponges from the epicontinental Triassic of Europe is not too extensive. This is mainly due to their sporadic occurrence and poor state of preservation. Until now, sponges were recorded only from few localities where they occur in various lithostratigraphical positions, but always within the Muschelkalk. From these localities, bodily preserved specimens, loose spicules and

- borings have been referred to hexactinellid sponges. However, the more exact systematical position is doubtful in most cases. During the last years, a lot of lyssacinosan sponges have been recorded for the first time both from well known and new localities. They were found in the lower Muschelkalk of Upper Silesia and of the Holy Cross Mts., where they occur locally in biohermal and biostromal accumulations. This material provides new information about Triassic sponges, which are presented here in their palaeontological, stratigraphical, and paleoecological contexts.</ABSTRACT>

72 <TITLE>Ecology and distribution of the Late Jurassic Scleractinian *Thamnasteria concinna* (Goldfuss) in Europe.</TITLE>
73 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 105: 311-335.</SOURCE>
74 <ABSTRACT>The quantitative investigation of associations in northern Germany revealed *Thamnasteria concinna* as their main element, necessitating an evaluation of all data for the spatio-temporal distribution of this scleractinian. Autecological criteria and sedimentological data indicate an optimum fitness of the coral in turbulent environments with low net-sedimentation rate. In these facies, no conflicting aims existed for *T. concinna* in exploiting light or plankton and resisting adverse hydrodynamic conditions. The most important synecological parameters of the associations studied are dominance patterns and diversity as well as the structure of guilds. *T. concinna* mostly constituted the builder guild, occurring as an ubiquitous, though dominant only in shallow water. As recorded in the study area, strong dominance of a few taxa and low diversity indexes are typical of immature communities in unstable environments. *T. concinna* was well adapted to varying environmental factors showing characteristics of an r-strategist, thus being more successful than other corals in stressful facies. The distribution pattern of *T. concinna* was not controlled by single environmental factors, but rather the oscillation of many of them. This seasonality is a typical feature of the temperate realm. *T. concinna* actually was important only in temperate regions of the Late Jurassic neritic sea or its borders with the Tethyan region. Further south, the coral was just one of the many members of the Tethyan reefs where mature communities predominated. Because of sedimentological restrictions, this pattern is most clearly visible in the Oxfordian, whereas *T. concinna* was a negligible element of Tithonian reefs. Its evolutionary decline is due to the concentration of reefs on the (sub)tropical Tethyan region.</ABSTRACT>

85 <TITLE>Paleobiological Controls of Jurassic Spongiolites.</TITLE>
86 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special

Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp 209-214.</SOURCE>

- 87 <ABSTRACT>Micro- and biofacies aspects as well as biogeochemical data of Jurassic spongiolitic limestones from Spain, Southern Germany and Romania allow to consider the following parameters to have controlled the spongiolitic megafacies: 1) Pro- and regradation of spongiolitic facies correlate with the sealevel development, progradation characterizing transgressive phases. Consequently, spongiolites are restricted to areas having had low sedimentation rates. 2) Spongiolitic and coral facies were in competition during the Jurassic. Factors, which favoured one boundstone type above the other were a) the bathymetry and the dependent parameters hydrodynamics and light intensity, and b) a constantly oligotrophic situation, which favoured a dominance of coral reefs, while spongiolitic mud mounds revealed certain tolerance to an episodically higher trophic level. 3) The formation of microbialitic (automicritic) crusts can be traced to heterotrophic activities, mainly with the aid of data from the microfacies investigations, and isotopic and biogeochemical analyses (Keupp et al. 1993). The spongiolithic facies was thus comparatively more independent from photic conditions and could form in a wide bathymetric range. 4) The spongiolitic facies, in which, conditioned by the bathymetric and hydrodynamic situation, automicrites and allochthonous mud deposition were continuously in competition (Leinfelder & Keupp 1995), reflect more-or-less the low energy habitat, while the coral facies is characteristic of the high energy level. 5) More-or-less cyclic successions within the spongiolitic facies, which affected the Porifera and other benthic associations as well as different types of microbialites (thrombolites, laminated peloidal crusts, aphanitic automicrites), on the one hand were controlled by hydrodynamic events and on the other by episodic oxygen fluctuations. 6) The conservation of spongiolitic mounds presupposed the formation of automicrites and the early diagenetic calcareous lithification of siliceous sponges ("Erhaltungsfenster"), which, besides the above mentioned environmental factors, depends on the taxonomic composition of the sponge fauna, with regard to different amounts of endosymbiotic bacteria (cf. Rehfeld, this volume).</ABSTRACT>

- 100 <ABSTRACT>In the course of the present work, the four common Belgian sponge species, Ephydatia fluviatilis, Ephydatia muelleri, Spongilla lacustris and Eunapius fragilis have been collected as well as a fifth species, Trochospongilla horrida. This species and its ecology have been rarely described in Europe and this is the first report on it from Belgium. Observations made with light and scanning electron microscopy have shown the presence of spicule morphological variations and malformations, associated with adverse environmental conditions or with transient or permanent pollution. Therefore, these modifications could be used as indicators of water quality. [first part of extensive summary]</ABSTRACT>

Investigation of Tabulata).</TITLE>
112 <SOURCE>Publishing House "Nauka"; Siberian Branch,
Novosibirsk: 128 pp., 30 pls. [in Russian, with English summary]</SOURCE>
113 <ABSTRACT>Tabulata distribution in Devonian in addition to
determination of geographical differentiation of marine faunas in
Eurasia are discussed. The biogeographical provinces, existing in the
early Devonian in Eurasia are identified as: Mediterranean,
Uralo-Tian-Shan, Jungaro-Balkhashskaya, Altai-Sayanskaya,
Indigiro-Kolymenskaya, Mongolo-Ochotskaya, Indo-Siniiskaya. Enlargement
of the provinces took place between the Middle Devonian and Frasnian
time. Climatic zonation is given apart from the hypotheses on the
location of the Equator and geographical Poles. The book may be helpful
for geologo-stratigraphical, research workers as well as
palaeontologists and zoogeographers.</ABSTRACT>

150 <TITLE>Hydroid-serpulid symbiosis in the Mesozoic and Tertiary.</TITLE>
151 <SOURCE>Palaeontology 18, 2: 255-274.</SOURCE>
152 <ABSTRACT>Several species of Mesozoic and Tertiary serpulids from Europe and the Middle East were infested by a colonial organism which is preserved as the mould of a stolonial network with polyp chambers buried in the peripheral zone of the calcareous tube. The polyp chambers open to the outer surface of the tube through small, usually semicircular apertures. The mould is the result of incorporation of the organism into the worm tube during calcification by the serpulid: it is not a boring. The organism is interpreted as a hydroid or group of related hydroids which lived commensally or possibly mutualistically with the serpulids. This hydroid-serpulid symbiosis is compared with the living symbiosis between the hydroids of Proboscidactyla and certain species of sabellid polychaetes. * The name of the fossil symbiont is Protulophila gestroi Rovereto.</ABSTRACT>

163 <TITLE>Western European and eastern Australian Mississippian shallow-water reefs: a comparison.</TITLE>
164 <SOURCE>Proceedings of the XVth International Congress on Carboniferous and Permian Stratigraphy, Utrecht, the Netherlands (Wong, Th. E. (ed.): 433-442.</SOURCE>
165 <ABSTRACT>Shallow-water reefs were a common element in the Mississippian successions of Western Europe and eastern Australia. They formed in different palaeotectonic settings, the stable southern shelf of Laurussia, near the collision zone of Armorica and Gondwana, and in the fore-arc setting of eastern Australia. Reef development in these areas responded to local and regional tectono-sedimentary patterns, and, therefore, the timing was different in the two regions. Shallow-water reefs occurred throughout almost the entire Mississippian. Australian reefs already developed at the Devonian/Carboniferous boundary, whereas European shallow-water reefs did not appear until the early Visean. The lack of Tournaisian reefs in Europe is only partly well constrained (unfavourable facies). Reef development ended in Australia somewhat earlier than in Europe. The youngest reefs formed on the southern shelf of Armorica. Reef termination scenarios in all regions included combinations of sediment influx, uplift, volcanism, and/or plate movements. Although individual reef development differed, three major reef-forming fabrics can be identified in both regions. Microbial communities were the most important reef fabrics and entire reefs consisted only of microbial framework. The second framework type consisted of microbial communities, corals, lithistid sponges, and bryozoans of relatively high diversity, but varying abundances. Coral-dominated facies, the third major fabric type, only became volumetrically important in Visean and Serpukhovian reefs, but, regardless, microbial fabrics were generally essential for reef formation. A large number of reefs consisted of a delicate balance of different reef builders, but a unique Pangean reef community is not evident. The formation of Pangea influenced reef formation in two ways. Firstly, the southward movement of the Australian plate made reef formation impossible, and plate

collision and tectonic uplift terminated reef development in Europe. Second, glacio-eustatic sea-level changes, a result of global climate change and associated glaciation in Gondwana, greatly affected reefs in inner shelf positions.</ABSTRACT>

216 <SOURCE>Senckenbergiana lethaea 82, 2: 515-543.</SOURCE>
217 <ABSTRACT>Seven Tabulophyllum-species of the European Devonian are revised and two species are described as new. Tabulophyllum lineatum (Quenstedt 1881) from the Sudetes is redescribed and taxonomically fixed by designating a lectotype. Tabulophyllum rotundum Fenton & Fenton 1924, T. sylvaticum Rohart 1988 and probably T. normale (Walther 1928) are synonyma of this species. All existing specimens of the taxa described by walther (1928) are completely figured for the first time and lectotypes are designated for Tabulophyllum brevissimum (Walther 1928) and Tabulophyllum tenuissimum (Walther 1928). Tabulophyllum leonense from Spanish Morocco and Tabulophyllum ? n.sp. aff. T. similis (Rozkowska 1979) from the Harz Mts (Iberger Kalk) are described as new. Federowskicyathus (Rozkowska 1979) is a probable new synonym of Tabulophyllum.</ABSTRACT>

230 <ABSTRACT>Macgeea is a cosmopolitan genus of Devonian rugose corals that includes numerous, generally highly variable, species. Because of its wide skeletal variation and additional trabecular dilation it is difficult to recognize taxonomically relevant characters and to separate those from ecologically induced modifications. The high variability is probably related to radiations following phases of sea level rise and is connected to bioevents. Length of major septa in ontogenetic stages allows a separation of different populations within the Macgeea dubia species group. However, it remains questionable if septal length is a reliable taxonomic character, indicating a phylogenetic trend, or if it is subject to large individual variability. By revising Macgeea dubia, we reveal its synonymy with Macgeea heterophylloides sensu Birenheide. In addition, Macgeea recta (type species of Pexiphyllum Walther 1929) is discussed as an insufficiently defined taxon of problematic status. Macgeea crassiseptata n.sp. is also described from the Late Givetian of Morocco. The erection of the new pseudocolumellate genus Baculophyllum

- with type species *Pexiphyllum ultimum* Walther 1929 requires a comparison with *Protomacgeea* from Poland and Australia as well as a phylogenetic discussion of the solitary *Phillipsastreidae*. The new genus most probably belongs to a separate lineage of the Upper Devonian *Macgeea* group but could also be considered as a descendant of the Australian Lower Devonian columellate solitary *phillipsastreid* species group, that has not yet been recorded from the Middle Devonian. Because of large stratigraphic gaps between the occurrences of both genera, preference is given to the interpretation of a development of polychromorph taxa (homeomorphic taxa living at a different time) not belonging to a single lineage. This shows again the significance of stratigraphic age when comparing similar-looking taxa, which should be considered in any phylogenetic reconstruction. </ABSTRACT>

384 <TITLE>Diversity of late Ordovician rugose corals in Baltoscandia: role
of environmental changes and comparison with other areas.</TITLE>
385 <SOURCE>Proceedings of the Estonian Academy of Sciences, Geology 53, 4:
233-245.</SOURCE>
386 <ABSTRACT>Corals colonized the Palaeobaltic Sea in the middle Caradoc.
A century and a half of studies have produced many significant results
related to their taxonomy and other aspects. A summary of the genus
level taxonomic composition of the Baltoscandian rugose coral
assemblages and some aspects of their diversity dynamics are presented
by B. E. E. Neuman and D. Kaljo in Webby et al. (2004b). * Recent
advances in Baltic isotope studies gave rise to the idea of using
isotope data, together with biodiversity data, to investigate the role
of environmental changes in the evolution and diversification of
corals. The well-known diversity curves of Sepkoski (1995) show a
generalized pattern of diversity change. Regional curves are more
environmentally controlled and reveal details that can be correlated
with stable isotope data, sea level curves, etc. These links are
employed here for better understanding of the environmental background
of certain bioevents. Conclusions are also based partly on the
palaeoceanic and palaeoclimatic models suggested by Jeppsson (1990) and
revised by Munnecke et al. (2003) for the Silurian Period.
Morphological novelties are the essence of coral evolution in leading
to the appearance of new taxa. Usually, the time pattern of the latter
process correlates somewhat with environmental changes and this allows
biodiversity to be taken as a qualitative measure of possible
ecological influence. Some useful pointers to this influence can be
obtained via correlation of the coral diversity data with the late
Ordovician carbon isotope trends. [excerpts from an introduction]

Bodophyllum duncanæ (Spjeldnaes 1961) from the Oslo Region.</TITLE>
411 <SOURCE>Coral Research Bulletin 05: 197-201.</SOURCE>
412 <ABSTRACT>A great number of cleaned silicified specimens of Bodophyllum
duncanæ (Spjeldnae 1961) from Upper Ashgillian Beds from the locality
Gunnkleiv in the Skien-Langesund District of the Oslo Region revealed
that this species had a liberossessile way of life in shallow marine
environment. Some specimens remained fixosessile also during the neanic
stage and developed a thicker cylindrical septate prolongation of the
corallite. The intraspecific rate of variation of different
morphological structures as a result of environmental influence is
discussed.</ABSTRACT>

502 <SOURCE>Grondboor & Hamer 55, 2: 1-144.</SOURCE>
503 <ABSTRACT>Over many years more than 60.000 silicified Ordovician
erratic sponges from the palaeocontinent Baltica have been collected in
some areas in Northern Europe. Especially in the Netherlands some
hundred enthusiastic amateur geologists have stored about 20.000
specimens in their private collections or housed them in museums.
However, appropriate literature to identify them properly is not
readily available. Either the literature is too old to be loaned out by
museums or institutes, or it is inaccessible to the average amateur,
due to both the scientific level and the need to read foreign
languages. The purpose of this volume is first of all to provide a
guide, a manual for Dutch (and German) amateurs. This atlas also serves
other purposes: It is also meant to give an overview of the current
knowledge of this subject at a time that sponges are the subject of
extensive research. Besides, there is presently a concentration of
knowledge, experience and availability of the material. The third
purpose is to draw the attention of sponge specialists throughout the
world to the extensive and varied sponge assemblages from Baltica. It
is remarkable that in the 19th century German sponge specialists, such
as Roemer, Rauff and von Zittel, were leading the research and even
examined American sponges. After that generation only a few European
palaeontologists continued these investigations. Over the years
American specialists dominated sponge research. Perhaps as a result of
this development Baltic sponges were gradually left out of
palaeontological focus. Perhaps this atlas will stimulate renewed
interest in these varied, sometimes wonderfully preserved, erratic
sponge assemblages. [from original English summary: introduction]

553 <TITLE>Middle Ordovician reefs of Norway.</TITLE>
554 <SOURCE>Lethaia 14: 169-188.</SOURCE>
555 <ABSTRACT>The Middle Ordovician reefs of Norway were the first to develop in the western part of the Baltoscandian epicontinental sea and are the earliest coral-stromatoporoid reefs so far reported in Europe. Small patch reefs in the Steinvika Limestone, Langesund-Skien district, consist mainly of algae, echinoderms, corals and stromatoporoids. Bryozoans, molluscs, athropods and brachiopods are also present. The reefs developed on pelmatozoan-rich substrates and are organically zoned, consisting of a pioneer community of stemmed echinoderms and sheet algae, a high-diversity intermediate community dominated by

- fasciulate corals and a low diversity climax community of massive corals and stromatoporoids. These communities are interpreted as the seral stages of an autogenic ecological succession. Small patch reefs are also present in the laterally equivalent Mjosa Limestone, Toten and Nes-Hamar districts. These are organically very similar to those in the Steinvika Limestone and developed in an identical way. A large complex, consisting of several reefs, is also present in the Mjosa Limestone. Unlike the reefs elsewhere, which developed with shallow inshore areas, this complex developed at the outer edge of the inshore shelf. The outstanding features of the complex is the main reef forming the offshore limit which is totally dominated by stromatoporoids and lacks a sequential development. This is due to the influence of the harsher environment at the shelf edge. [original summary] </ABSTRACT>

567 <SOURCE>Senckenbergiana lethaea 54, 5/6: 475-489.</SOURCE>
568 <ABSTRACT>The present paper lists those type specimens of Rugosa described by wedekind (1927) from the silurian of Gotland and from the Ordovician-Silurian of the Oslo region which are deposited in the Forschungs-Institut Senckenberg, Frankfurt am Main. Lectotypes are chosen when wedekind has designated more than one specimen as " Typus der Art" ("type of the species"). The strata typica given by wedekind are - as far as possible - supplemented by modern names (standard stratigraphy of Gotland by Manten 1971). An additional list contains all names of species introduced by wedekind 1927 of which neither holotypes nor lectotypes are deposited in the Forschungs-Institut Senckenberg.</ABSTRACT>

594 <ABSTRACT>Eighty-eight species of Stromatoporoids have been described
from all the regional stages of Estonia from lower Ashgill to lower
Pridoli. The ranges of the 26 genera are plotted in a large table (31).
The distribution of these genera in the various stages is briefly
discussed. Labechiids are relatively rare in the Ordovician rocks at
the bottom of the sequence; they are joined in younger Ordovician rocks
by clathrodictyids. In the Llandovery clathrodictyids make up 80 % of
the fauna and labechiids are next in abundance. Many new families
appear in the Llandovery: atelodictyids, actinostromatids,
gerronostromatids and pseudolabechiids. In the wenlock beds occur the
first densastromatids and the first representatives of the orders
Stromatoporida, Stromatoporellida and Syringostromatida. The diversity
maximum in Estonia was reached in the Ludlow Stage. The richest
Stromatoporoids faunas are found in rocks deposited in high energy
shoal environments.</ABSTRACT>

607 <ABSTRACT>Twenty-eight stromatoporid communities are defined, spreading
in Upper Ordovician and Silurian deposits of Estonia, Sweden (Gotland),
and Norway (Oslo Region). The communities are linked to the Standard
Benthic Assemblages (BA) after Boucot (Evolution and Extinction Rate
Controls, 1975). Successive stromatoporoid faunas consist of
imperfectly delimited lateral communities of different stratigraphical
range and taxonomical diversity. The richest communities occur in the
reef (shoal) facies corresponding to BA2. These have the shortest
stratigraphical range and are laterally replaced by less diverse
long-range communities. [original abstract]</ABSTRACT>

Poland.</TITLE>
619 <SOURCE>Palaeontologia Polonica 18: 1-112.</SOURCE>
620 <ABSTRACT>The paper deals with the results of a detailed morphological
and taxonomical investigation on the Tabulata from Norway, Sweden
(Island of Gotland) and from the erratic boulders of Poland. The
stratigraphical correlation of the Silurian in the above mentioned
areas and in Estonia is given. These studies have also thrown some new
light upon the development of Tabulata during the Silurian in the
Scandinavian-Baltic region. A hundred and seven species assigned to

- twenty-six genera are described. Thirty-six of the species and four of the genera (*Solenihalysites* n.gen., *Sparsisolonia* n.gen., *Kiaerites* n.gen., *Fayosipora* n.gen.) are new ones. Moreover, a new family (*Angoporidae*) has been established

633 <ABSTRACT>Due to the favourable climatic and shallow-water conditions in the Estonian part of the Baltic Basin, tabulates played a significant role in the Late Ordovician and Silurian faunal assemblages. In Estonia, the earliest tabulates are known from the Late Caradoc. *Lyopora tulaensis* Sokolov, *Saffordophyllum grande* Sokolov, *Eoflecheria orvikui* Sokolov, occur in the Vasalemma reef facies of the Oandu Stage. At the beginning of the Late Ordovician, the conditions for tabulates were unfavourable, therefore the fossils are rare. Only one species, *Catenipora obliqua* (Fischer-Benzon) has been recorded from the Nabala Stage. Diversification of the Late Ordovician tabulate fauna began in the Vormsi Age with the appearance of the first Paleofavosites - *P. schmidti* Sokolov and *P. borealis* Tshernyshev. The most ancient heliolitids (*Wormsipora*, *Esthonia*, *Protaraea*) are also known from the Vormsi Stage. *Sarcinuliids* and *halysitids* (*Catenipora*) became common for the first time. During the Pirgu Age diversification continued. The tetradiids (*Cryptolichenaria multiplex* Klaamann) appeared for the first time in the Baltic area. The *halysitid* *Eocatenipora* was widely distributed and early heliolitids were well developed. The Late Ordovician favositids were blooming in the Porkuni Age. The first records of *Porkunites*, *Mesofavosites* and *Priscosolenia* are from the same age. The beginning of the Silurian was a time of rapid diversification of *Mesofavosites* and *Paleofavosites*. [first part of extensive summary]</ABSTRACT>

658 <SOURCE>Publications Service Géologique Luxembourg 29: 39-47.</SOURCE>
659 <ABSTRACT>Coral, stromatoporoid and algal reefs were developed in the marginal part of the gulf-like Baltic cratonic basin in Gotland, north and central Estonia, and east to central Lithuania. They are situated at different stratigraphic levels from the middle Caradoc up to the lower Pridoli. Their appearance coincided with the transition of the Baltic Basin from an epicontinental to pericontinental phase of development, and with shifting from a temperate to the tropical climatic zone. Most of these reefs had a flat or lenticular shape, as they grew in conditions of relative tectonic and eustatic stillstand. Extensive progradation of the reef belt took place during general regression of the basin at these times. The role of stromatoporoids increased in frame building towards the end of the Silurian. Shoal-barrier type reef tracts, developed at different stratigraphic levels, were situated in the middle part of a broad carbonate shelf (platform) on the SW margin of the Baltic craton. This contrasts with Recent barrier reefs, usually located at the shelf edge of eastern margins of continents.</ABSTRACT>

- 684 <SOURCE>Akademiya Nauk Estonskoy SSR; D. Kaljo & E. Klaamann (eds):
Ecostratigraphy of the East Baltic Silurian: 35-40.</SOURCE>
- 685 <ABSTRACT>In conclusion it can be said that during the whole Wenlock
and Ludlow reefs were characteristic of the northern part of the
Paleobaltic. They are especially abundant on Gotland, where at least 9
levels with reefs of different age have been preserved. Suggesting
general regression of the basin, they replaced regularly each other
towards the South and Southwest. The coincidence of the succession on
Gotland and in Estonia shows the presence of reef belts situated
roughly parallel to the shore line. This succession was partly
interrupted at the end of the Wenlock at the time of Silurian maximum
regression (in Rootsikula time) when reef formation took place only on
Gotland (evidenced by buildups in the uppermost Halla Beds, the Mulde
and Klinteberg Beds). [original summary]</ABSTRACT>

- 696 <TITLE>A Lingula-Heliolites association from the Silurian of Gotland,
Sweden.</TITLE>
- 697 <SOURCE>Journal of Paleontology 50, 5: 858-864.</SOURCE>
- 698 <ABSTRACT>In the Silurian Hemse Group (Ludlovian) of Gotland, Sweden,
Lingula occurs in burrows in Heliolites interstinctus Linnaeus and
rarely in Densastroma podolicum (Yavorskiy). Statistical analysis of
patterns of burrow occupancy and mode of burrow construction suggests
that Lingula did not make the burrows, but occupied them after they
were abandoned by the burrowing organism. Lingula preferred to occupy
burrows in living Heliolites colonies, and was usually able to keep the
burrows open in spite of continued coral growth. The relationship is
interpreted as commensal, benefiting Lingula by providing a solid
substrate and perhaps nematocyst protection from would-be predators.
The virtual restriction of the relationship to Heliolites is attributed
to the open structure of the Heliolites skeleton and its slow growth,
as compared with the other available colonial coral, Favosites.

761 <TITLE>Atractosella, a Silurian alcyonarian Octocoral.</TITLE>
762 <SOURCE>Journal of Paleontology 55, 2: 281-294.</SOURCE>
763 <ABSTRACT>Fusiform calcitic spicules occur abundantly in the Lower and Upper Visby beds and sparsely in the basal Hoegklint Beds on the Island of Gotland in the Baltic Sea. The stratigraphic interval spans the uppermost Llandoveryan to lowest Wenlockian. The spicules can be referred to the genus Atractosella Hinde 1888, previously interpreted as a sponge. The new species A. cataractata is described on the basis of the Gotland material. The spicules are built up of concentric layers, representing stages of growth. The surface is usually covered with granula or small thorns. The calcite shows good alignment of the c axes parallel to the the spicule axis, but the direction may deviate up to $\pm 8^\circ$ between opposing sides of the spicule. Occasional branched spicules are interpreted as fused adjacent normal spicules. Two natural spicule associations on a bedding surface show the organism to have had a rounded outline and a diameter of a few centimeters. In all the investigated characters, Atractosella is indistinguishable from a modern soft coral of the family Alcyoniidae. It is interpreted as the earliest known representative of the octocoral order Alcyonacea, extending the range of this group from the Lower Jurassic to the Lower Silurian. Mirmor andreae Lamont 1978, described originally as an ostracoderm, is reinterpreted as a species of Atractosella. A. cataractata is common in fine-grained sediments and may have lived attached to hard objects on soft bottoms. [original summary]</ABSTRACT>

852 <TITLE>Some aspects of life strategies of Early Palaeozoic rugose corals.</TITLE>
853 <SOURCE>Lethaia 21: 97-114.</SOURCE>
854 <ABSTRACT>Examination of some well-preserved specimens of Silurian rugose corals from Gotland reveals that the following categories of life strategies can be distinguished: ambitopic, liberosessile, fixosessile, rhizosessile and possibly limited vagile. Most solitary rugose corals appear to have been liberosessile and are characterized by initial attachment to a small sediment grain but subsequently becoming recumbent on a soft substrate. Detailed studies of *Phaulactis angelini*, *Holophragma calceoloides*, *Laccophyllum lindstroemi*,

- Rhegmaphyllum conulus and Rhabdocyclus ocksarvensis n.sp., and comparison with earlier described species, provide some new aspects on different life strategies for solitary corals.</ABSTRACT>

892 <SOURCE>Paleont. Contr. Univ. Oslo 278 [D. Worsley(ed.): Field Meeting Oslo Region 1982; IUGS, Subcomission on Silurian Stratigraphy]: 33-42.</SOURCE>
893 <ABSTRACT>Rugose corals are well represented in late Ordovician and Silurian rocks of the Oslo Region, but very few Silurian taxa have yet been described or correctly identified. Some rugose corals representative for the different silurian formations are here listed and illustrated. At present, the stratigraphic value of the silurian rugose corals from the Oslo Region is limited, but the comparatively rich faunas have an undoubted potential in this respect. 906 <ABSTRACT>Analysis of literature concerning the silurian colonial
corals with an inner wall and investigation of a collection of those
corals from the Silurian of Podolya, allow reinforcement of the opinion
that these corals with an inner wall belong to only two genera
(Acervularia and Diplophyllum). * Two species of Acervularia are
described from Podolia: A. ananas (Linne 1758) of wenlockian age, and
A. sokolensis n.sp. of Ludlowian age. * Measurements of the latter:
corallite diameters about 14mm, number of septa up to 48, tabularium
diameters up to 5mm, tabulae 6-12 within 5 mm. One row of dissepiment
between outer and inner wall, rarely two rows but inside the wall there
are one to three rows.</ABSTRACT>

917 <TITLE>Cladistic analysis of entelophyllid rugose corals from the
Silurian of northern Europe: some methodological aspects.</TITLE>
918 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the
8th International Symposium on Fossil Cnidaria and Porifera]: 050-061.
</SOURCE>
919 <ABSTRACT>The construction of a character taxon matrix is fundamental
to cladistic analysis, and some of the methodological issues involved
in the making of such a data matrix are discussed. Three aspects are
emphasized: (1) character construction, (2) coding procedure, and (3)
the use of non morphological data. Characters used in cladistic
analyses are constructed, on the basis of observed variation, in a
manner that fits a specific taxonomic problem. In rugose coral species,
morphological variables are commonly continuous and quantitative. There
is a subtle interaction between observation of variables and semantics
of character naming, with non trivial implications for parsimony
analysis. Character coding can be approached in several ways, and two
contrasting methods of coding are considered: (A) composite (multi
state) coding, and (B) reductive (absence/presence) coding. Skeletal
morphology may be insufficient for resolution of rugose coral
phylogeny, suggesting the use of additional sources of data. Methods of
incorporation of stratigraphic information in the data matrix pay
little attention to the nature of the sedimentary record, and a more
rigorous evaluation of relationships between stratigraphy and phylogeny
is recommended. Examples are drawn from a preliminary study applying
cladistics to entelophyllid rugose coral species from the Silurian of
northern Europe. Consensus cladograms from alternative search settings
are here included to illustrate effects of different approaches.
Specific choice of procedure affects homology assessment, character
distribution, and tree topology. If the data matrix is to be accessible
to other workers, and subject to testing, the construction of the data
matrix must be made explicit as far as possible. [original abstract]

931 <SOURCE>Geological Magazine 06: 519-523.</SOURCE>
932 <ABSTRACT>Silurian fossils have been identified from Oscar II Land, western Spitsbergen. They are the first Silurian fossils from Spitsbergen and threw new light on regional correlations and dating of Palaeozoic orogenic events in the region. The corals mentioned are the rugosan genera Ketophyllum, Dokophyllum, Tryplasma, Phaulactis and the tabulate coral Palaeofosites and Catenipora. [part of original summary]

983 <SOURCE>Palaeontology 27, 1: 113-130.</SOURCE>
984 <ABSTRACT>Stromatoporoids in argillaceous level-bottom limestones of the Upper Visby Beds in the Silurian of Gotland, Sweden, show a variety of features of growth forms, within a spectrum of coenosteal shapes from laminar through low to high domical. Many coenostea show interdigitations of sediment in their margins, attributable to intermittent sedimentation, while others show abrupt changes in growth direction, which are the result of movement, often leading to overturning. Stromatoporoids frequently survived these agents and continued to grow, often resulting in different morphotypes from those which would have been produced in the absence of sedimentation and movement; serious problems of shape identification and shape classification exist as a consequence. Variations in the effects of sedimentation and movement are recognizable in the specimens studied and the Stromatoporoids therefore record a variety of events occurring at the sea bed during their lives.</ABSTRACT>

1009 <SOURCE>Sedimentology 49, 3: 379-395.</SOURCE>
1010 <ABSTRACT>Stacked stromatoporoid-dominated biostromes of the Ludlow-age Hemse Group (Silurian) in eastern Gotland, Sweden, are 0.5-5 m thick and a few tens of metres to >1 km in lateral extent.They form one of the world's richest Palaeozoic stromatoporoid deposits. This study compiles published and new data to provide an overall facies model of these biostromes, which is assessed in relation to possible modern analogues. Some of the biostromes have predominately in-place fossils and are regarded as reefs, but lack rigid frameworks because of abundant, low-profile, non-framebuilding stromatoporoids: other biostromes consist of stromatoporoid-rich rudstones interpreted here as storm deposits. - 1062 <ABSTRACT>Sixteen species of various morphologies occur in the Kuppen bioherm. Some, such as Clathrodictyon mohanicum have a specific growth style (laminar to low domical) yet others (eg. Plectostroma intermedium) show a range of growth forms from low to high domical that suggests phenotypic plasticity but actually results only from some individuals growing longer than others. Taller forms were more commonly turned over by storms. Some species responded to environmental gradients by modifying growth form. Most stromatoporoids grew on stable substrates provided by dead stromatoporoids. Cathodoluminescence suggests they secreted calcite.</ABSTRACT>

1114 <ABSTRACT>These reefs are formed during phases of reduced clastic
supply. Hogklint reefs began as bioherms and were replaced by
biostromal phases as water shallowed. Low clastic supply reduced not
only the clay input but also lowered nutrient levels. Modern reefs
develop best in low nutrient conditions and show suppressed bioerosion
and increased symbiosis. Hogklint and Hemse reefs are interpreted as
having grown in nutrient-deficient conditions. Reef growth could
ultimately be controlled by eustatic changes or climate control. A
model of alternating wet and dry episodes interpreted as CO₂-driven is
proposed.</ABSTRACT>

1127 <ABSTRACT>Stromatoporoid-dominated biostromal reefs of Ludlow age in

- Gotland. Sweden, are well-known to display a densely packed suite of stromatoporoid growth forms from laminar to tall domical which are species or genus specific. Biostrome facies comprise clays and packstones / grainstones containing debris of stenohaline marine groups (crinoids, bryozoa, brachiopods), supplemented by debris of reef-building stromatoporoids and corals. Recent sampling reveals previously unresearched significant differences in stromatoporoid growth forms, of the same morphospecies, in stratigraphically-closely related biostromes, in broadly similar environments. 1140 <ABSTRACT>The morphological range of stromatoporoids is strongly related to depositional environment. In high energy environments, characterized by packstones and grainstones, low profile forms predominate, whereas in calmer settings, characterized by wackestones and packstones, high profile stromatoporoids dominate. Four rock units are recognized, representing two major facies: reeflike limestones and detrital grainstones. Reeflike limestones comprise a variety of lithologies including wackestones, packstones, boundstones, and framestones. All units are shallow marine but the occurrence of crystal silt may indicate a vadose situation on the top of the reeflike facies. In the reeflike units hard substrates for stromatoporoid growth were probably provided by microbial sedimentation. Sedimentation rates were generally low although episodic high sedimentation occurred as indicated by raggedness in stromatoporoid skeletons. The stromatoporoid fauna is considered a low diversity assemblage dominated by *Parallelostroma typicum*. Other species found are: *Pycnodictyon densum*, *Stromatopora venukovi*, *S. bekkeri*, *Petridiostroma convictum*, *Ecclimadictyon robustum*. Since measurements of skeletons were made in the field, and due to limited amount of sampling, species confined to certain shapes were not distinguished.</ABSTRACT>

1151 <TITLE>Cathodoluminescence of Silurian stromatoporoids from Gotland.</TITLE>
1152 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 307-318.</SOURCE>
1153 <ABSTRACT>Cathodoluminescence (CL) response of stromatoporoids from the Silurian of Gotland, Sweden, varies from none to brightly luminescent. The greater contrast shown with CL can help with identification of poorly preserved stromatoporoids. In normal light, stromatoporoids show

a range of alteration of skeletal structure from apparently well preserved to strongly altered. In cross-polarized light, skeletal elements are overprinted by large, bladed to irregular calcite crystals, even in apparently well-preserved specimens, and irrespective of microstructure, thereby demonstrating at least partial alteration in all samples examined. The most common stromatoporoid microstructure, termed compact, consists of irregularly arranged micritic calcite crystals, which show a trend towards aggrading neomorphism when altered; this is seen most clearly under CL. The CL response in relatively well-preserved stromatoporoids with a compact structure normally consists of a speckled mixture of micritic non-, dull and bright luminescent crystals, also micritic in normal light. This is probably close to its original texture, and earlier SEM studies by others concur with this. Recent work shows that modern shells can luminesce, and exhibit a range of CL response, even in different individuals of the same species, reflecting minor variations in the skeletal composition. Therefore, the variation of intensity of CL in the speckling within stromatoporoid microstructure may indicate original compositional variations, but in view of the partial recrystallization of even well-preserved skeletons, separating CL response of the original microstructure and that of diagenetic alteration, is not practicable. However, in the present material, CL response generally shows the same textural features as the normal light view, and so the main advantage of its use is that these are more clearly seen under CL. Stromatoporoids are normally more recrystallized than brachiopods and rugose and tabulate corals (interpreted originally Low Mg calcite), but better preserved than molluscs of originally aragonitic composition. This has led to previous suggestions of a High Mg calcite composition, but variation of state of preservation between species in the same facies suggests variation in original skeletal mineralogy; different stromatoporoid species probably secreted either aragonite or High Mg calcite skeletons, with the possibility of varying Mg concentrations.</ABSTRACT>

1165 <SOURCE>Sedimentary Geology 89: 325-335.</SOURCE>

1166 <ABSTRACT>Lower Wenlock bioherms grew during a relative sea-level fall, on substrates of limited lateral extent and sediment accumulated around and on the reefs as they grew. Middle Ludlow biostromes were determined by low levels of clastic supply, laterally extensive suitable substrate, relatively stable sea level and largely flat sea beds in shallow-water conditions. The biostromes contain high and low profile forms and show differences from upper Ludlow representatives of the same species which are low profile only. Controls on growth may include: substrate consistency, environmental energy, and closer adaptation by the same species between middle and upper Ludlow times. Biostromes on Gotland may form when sea level is stable and a dry climate ensures low clastic input.</ABSTRACT>

1178 <SOURCE>Journal of Paleontology 55, 6: 1284-1295.</SOURCE>
1179 <ABSTRACT>A biostrome at Kuppen, in the middle Ludlow Hemse Beds (Silurian) on Gotland, Sweden, is dominated by densely packed laminar, domical and bulbous stromatoporoids to the exclusion of almost all other organisms. Within the biostrome two contrasting growth forms developed, growing together in the same environment. Clathrodictyon mohicanum Nestor forms laminar to low domical shapes, while Stromatopora bekkeri Nestor and Plectostroma scaniense Mori developed higher domical and bulbous shapes. The interactions between environmental factors and the genotype brought about the development of characteristic shapes (phenotype) for each species. P. scaniense and C. mohicanum show these and other morphotypes elsewhere on Gotland, while S. bekkeri forms only higher domical shapes within the limits of its known occurrence on Gotland. P. scaniense has the greatest potential genotypic plasticity for shape variability and shows a sensitivity to the environment not shared by the other two species. Variations in environmental conditions and changes in selection pressures and functional requirements of stromatoporoids appear to be responsible for shape variations. Identifying genetic components of shape, and showing how they relate to associated faunas and environments should make interpretations of stromatoporoid morphology more meaningful. 1191 <SOURCE>Akademiya Nauk Estonskoy SSR; D. Kaljo & E. Klaamann (eds): Ecostratigraphy of the East Baltic Silurian: 43-50.</SOURCE>
1192 <ABSTRACT>The present paper distinguishes five successive stromatoporoid communities spread in the shallow water sections of the Baltic Silurian Basin, in the stratigraphical interval corresponding to the Wenlock series by now accepted correlations. In the ascending order they are: Stromatopora impexa, Vikingia tenuis, Ecclimadictyon astrolaxum, Labechia conferta and Parallelostroma tenellum Communities. However, there is a possibility that the last community already belongs to the lowermost Ludlow. Potentially these communities may serve as a basis for a zonal stromatoporoid standard of the Baltic and adjacent regions. In the same stratigraphical interval in deeper water, marginal areas of the distribution of stromatoporoids, two communities are distinguished: Densastroma pexisum and "Pycnodictyon" densum. 1203 <TITLE>Sedimentary history of Upper Silurian biostromes of Podolia (Ukraine) based on stromatoporoid morphometry.</TITLE>
1204 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 271, 3-4: 225-239.</SOURCE>
1205 <ABSTRACT>The sedimentary history of stromatoporoid biostromal accumulations reflecting various depositional conditions (autoparabiostromes and parabiostromes) is studied in two isochronous, Late Silurian carbonate sections of the Malynivtsy Formation from Podolia (western Ukraine, Kam'janec' Podil'skyj area). This study focuses on morphometrical analysis of massive stromatoporoids. Various stromatoporoid attributes, such as growth form, volume, surface character etc., are interpreted in terms of growth environments. Attributes of redeposited specimens are also analysed in terms of their susceptibility to exhumation and redeposition, and new criteria are presented in this matter. The exposed facies succession, which can be subdivided into three units: an oncolitic-fenestral complex and the stromatoporoid-coral complexes that underlie and cover it, represents the belt of shoals located at a considerable distance from shore, and its transition to a narrow zone of back-shoal tidal flats. The facies patterns proved to be strongly obscured by an intensive process of onshore redeposition of material during high energy episodes. These events caused exhumation and landward transport of stromatoporoids inhabiting soft-sediment bottoms of outer shelf areas, which were afterwards accumulated in parabiostromes in calm waters on lee side of a zone of shoals. The main process governing the distribution of redeposited stromatoporoids is fractional (weight) segregation. The high energetic events had less effect on stromatoporoid-coral autoparabiostromes that formed the zone of shoals, which were inhabited by stromatoporoids better adapted to permanent wave action, but nonetheless, they caused their partial reworking and depletion from those forms that did not resist redeposition, on the one hand, and supplementation by specimens derived from offshore areas, on the other. 1216 <TITLE>Stromatoporoid-coral intergrowths in a Silurian biostrome.</TITLE>
1217 <SOURCE>Lethaia 20, 4: 371-380.</SOURCE>
1218 <ABSTRACT>Four stromatoporoid species from a stromatoporoid biostrome in the middle Ludlow Hemse Beds, Gotland, Sweden, show intergrowths with syringoporid tabulate and rugose corals, and indicate close relationships between particular coral and stromatoporoid species. The stromatoporoid Clathrodictyon convictum always contains ?Syringopora and this tabulate is rarely found in the other stromatoporoids. C. convictum is also closely associated with Tryplasma flexuosum (rugosa) while Petrozium pelagicum (rugosa) occurs only in the stromatoporoids Plectostroma intermedium and Parallelostroma typicum. The microstructure of ?Syringopora within the stromatoporoids is composed of an inner lamellar layer and an outer radial layer of calcite crystals. Diagenetic alteration has affected the microstructure which differs from recently described Devonian forms having only a radial layer. This shows variability in the structure of the tabulates within stromatoporoids. Information is sparse on the range of such variation and assessment of the relative importance of taxonomic,

palaeoenvironmental and diagenetic effects is not possible in the present sample. No evidence is found to prove the precise nature of the relationships; they were not parasitic but may have been mutually symbiotic, or (most probably) commensal. The results suggest that the corals selected the most suitable stromatoporoid species for their requirements. Stromatoporoid morphology may have had an important influence on the association, where corals are more abundantly associated with those stromatoporoid species which adopted a high profile. Overall the associations appear to have allowed the corals to explore higher energy habitats otherwise unavailable to their delicate branching structure.</ABSTRACT>

1230 <SOURCE>Scripta Geologica 044: 1-43.</SOURCE>
1231 <ABSTRACT>Five facies are recognized in the Upper Burgsvik and Lower Hamra-Sundre Beds on account of a lithological and paleobiological analysis : I) siliciclastic. II) bioclastic, III) oolitic/pisolitic, IV) oncolitic/biostromal, and V) crinoidal facies. The facies represent five depositional environments : a beach, a fore-shore, a surf, a shallow marine current, and an off-shore environment. The diversity and colony shape of tabulates in facies IV is related to discrete physical and biological factors. The succession of facies reflects a transgressive sequence. Land was situated in the north-west.</ABSTRACT>

1242 <TITLE>Ueber die silurischen Tabulatenassoziationen Estlands und der Insel Gotland.</TITLE>
1243 <SOURCE>Academy of Sciences Estonian SSR, chem. geol 26 (3): 203-210.</SOURCE>
1244 <ABSTRACT>This paper compares the silurian Tabulate associations of the Baltio area with those of the island of Gotland (Sweden). These faunas are of great importance for zonal formations in the Baltic-Scandinavian area. During the silurian time the Tabulate corals lived in shallow and detritic facies (Kaljo 1970). In the silurian time a corresponding fauna with equivalent genera and species is mostly found in Estonia as well as on the island of Gotland. But some differences occur which are laid down in the following. During the middle and late Llandovery Gotland lacks a coral fauna. Thereafter, in the upper Llandovery two faunal associations exist: in Estonia the Mesofavosites obliquus - Favosites favosus group. At the same time the Favosites stoermeri group is found on Gotland and in Norway. During the wenlockian time Estonia shows a restricted poor fauna, whereas on Gotland the rich F. lichenarioides - Pachypora lamellicornis group is typical. From the Hogklint or Jaani stage onwards both areas again show similar

development. with the beginning of the Ludlow a lagoon facies, characterized by Parastriatopora commutabilis association, is found in Estonia, whereas the former conditions continue on Gotland. A greater unification is typical since the Hemse-Paadla stage. The F. subgothlandicus group follows the F. effusus association. But in the Baltic area the first one can be subdivided by Thecia swinderniana and the younger Laceripora cribrosa. The Paadla-Hemse fauna is widespread; species of this association are found in the Northern Ural, the Siberian platform, Central Asia and Podolia. Since the Upper Ludlow the Tabulate corals are retrograde. In Estonia three different groups are to be distinguished: the older F. forbesi - F. similis group, the F. pseudoforbesi muratsiensis - Paleofavosites moribundus group and the youngest F. pseudoprhaei ohesaarensis group. Because the upper two groups are liiokinp on Gotland, it is concluded that the Silurian is more complete in Estonia in the lower part as well as in the uppermost part.

1294 <TITLE>Significance of a Halysitid-Heliolitid mud-facies autobiostrume from the Middle Silurian of Gotland, Sweden.</TITLE>
1295 <SOURCE>Palaios 15, 6: 511-523.</SOURCE>
1296 <ABSTRACT>A low-diversity halysitid-heliolitid autobiostrume from the Late Wenlock Halla Formation at Blåhäll 1, Gotland, indicates a brief period of particular environmental conditions. The reef is 0.3-0.5 m thick, internally without bedding structures, and had a sheet-like distribution on a low-relief soft-bottom, in marginal platform, graptolitiforous strata (height-width ratio is 1:900 in outcrop). The dominating coral species building this mud-facies biostrume were the tabulates Stelliporella cf. parvostella and Halysites latitenatus. The rugose coral fauna is dominated by fixosessile and rhizosessile forms with well developed holdfasts, for example Dokophyllum elegantulum. Coral growth forms generally indicate high background sedimentation rates during the growth of the biostrume. Four successive stages of sea-floor development are discussed: (1) a pre-biostrume stage, (2) a pioneering community stage, (3) a climax-community stage, and (4) a post-biostrume stage. Stratigraphically, these stages show an increased carbonate-siliciclastic ratio, a decreased phosphorus content, somewhat lighter δ^{18} stable isotopes, and an increased rate of bioturbation. The climax-community stage coincides with a bloom(?) in paleocopid and metacopid ostracods. The biostrume differs from all other Wenlock-Ludlow reefs on Gotland in its geographic and stratigraphic isolation on the seaward slope of the carbonate platform. It was the first re-appearance of a reefal structure following the oceanic Mulde Event and associated eustasy. On a regional scale, this appearance coincide with an inferred high-stand systems tract and the onset of widespread reef growth in the basin indicating that, at least, basin-regional factors controlled reef growth.</ABSTRACT>

- 1309 <ABSTRACT>The morphology of two species, Halysites catenularius (Linnaeus, 1767) and Paleofavosites asper (Orbigny, 1850), is statistically analysed based on numerous specimens. The specimens of H. catenularius, collected from the biostrome at Ireviken 3, Gotland show no particular change in intracolony variation, but shape and size of lacunae are variable. However P. asper from the Slite Beds in Gotland shows very large variation of corallite size and corallum shape both within and among localities. Species with large morphological variation are widespread and difficult to deal with taxonomically. [original abstract]</ABSTRACT>

- 1322 <ABSTRACT>The tabulate species of the genera Paleofavosites, Favosites, Parastriatopora, Propora, Aulopora and Catenipora recorded in Jämtland, Sweden, Scandinavian Caledonides, are taxonomically revised. Biometrics is used for species definition. The intraspecific variability is considered, and the analyses of type material and other similar specimens from Estonia are included in the taxonomical section. The neotype of Catenipora distans is illustrated and remeasured together with two other specimens from the same locality. Paleofavosites primus is synonymised with P. hystrix and Favosites favosiformis is synonymised with F. favosus. Several species are tentatively synonymized, what mostly demonstrates the problem of typological species in Baltoscandia. The tabulates known from Jämtland are also found in Estonia. The close relation of the development of tabulate faunas in both areas is suggested. The stratigraphical position of the Ede Formation at Ede, and the Berge Formation at Verkön and Norderön is discussed, comparing the tabulate successions from Jämtland and Estonia. The tabulate record from the Berge Formation proves the Aeronian age of the unit. [original abstract]</ABSTRACT>

- 1335 <ABSTRACT>Different aspects of intraspecific variation in Wenlock tabulate corals are discussed. Intracorallum and intraspecific

variation is demonstrated in specimens within the collection from one locality. The diagnostic characters of *Halysites senior* Klaamann and *Catenipora oriens* Klaamann and those of *Paleofavosites secundus* (Klaamann) and *Favosites jaaniensis* Sokolov overlap and therefore these species are regarded as synonyms. *Propora raricellata* Sokolov is a possible synonym of *P. tubulata* (Lonsdale), because the character differentiating these species is variable. </ABSTRACT>

1347 <SOURCE>Estonian Journal of Earth Sciences 56, 3: 143-156.</SOURCE>
1348 <ABSTRACT>*Paleofavosites* cf. *collatatus* Klaamann occurs abundantly in marls and bioherms of the Muksha Member of the Bagovitsa Formation (Upper Silurian, Ludlow). The morphological variation of this species identified in different localities is analysed. The biometrical data show that there is no substantial variation among specimens from different localities except that corallum shapes are taller in marls than in bioherms and corallites are slightly smaller in specimens from bioherms. The irregular growth of coralla is common to this area.</ABSTRACT>

1374 <ABSTRACT>We give new data on the structure and the microstructure of the genus Kiaerites Stasinska 1967, based on the examination of the type specimen of the type species, K. norvegicus Stasinska 1967 and of two other colonies from the Llandoveryan of Norway. The morphological fundamental characters are the convex tabulae with locally tabular spines and the numerous oblique trabecular spines in the walls. The microstructure is characterized by sclerenchyme composed of lamellae in tectiform arrangement along a median lamina which for its part is composed of plaquettes - this arrangement was until now unknown in the Tabulata; the spines are fibrous. Fossils of Kiaerites seem to occur frequently in Llandoveryan and Wenlockian beds of Europe and North America. The genus is assigned to the family Favositidae Dana 1846.</ABSTRACT>

1411 <TITLE>On the Tabulata assemblages in the Silurian of the East Baltic.

- 1412 </TITLE>
<SOURCE>Eesti NSV Teaduste Akad. Toimetised 21, Keemia Geologia 1:
78-82.</SOURCE>
- 1413 <ABSTRACT>Five facies belts have been distinguished in the Silurian of
the East Baltic Area, which are tentatively referred to as follows
(from the shore towards the open sea): the lagoonal, the shoaly, the
detritic, the transitional and the off-sea facies. The lagoonal facies
is mainly represented in the Ludlovian and characterized by ramose and
cylindrical tabulate corals (Parastriatopora, Laceripora); favositids
occur extremely rarely and represent casual immigrants from the shoaly
facies. The majority of Tabulata species of the East Baltic Silurian is
restricted to the shoaly facies. Within this facies we may distinguish
a relatively shallower part (reef region) and a deeper one (off-reef
region); they differ from each other by a different species content. In
the process of evolution of Tabulata, the shoaly facies was of the
greatest significance, and in the prochoresis likewise. In the detritic
facies, the significance of fasciculate forms increases, with
eurifacial species playing the predominant role. In the transitional
facies, the Tabulata occur sporadically and their assemblage may be
regarded as a considerably impoverished assemblage of the detritic
facies. No Tabulata have been found in the off-sea facies so far.

1424 <TITLE>Environment and quantitative morphology of some Silurian
tabulates from Gotland.</TITLE>
1425 <SOURCE>Scripta Geologica 047: 1-75.</SOURCE>
1426 <ABSTRACT>An outline is given of reef development in Gotland, Sweden,
during the time when the Visby (Llandovery) and Hogklint (Wenlock) Beds
were deposited together with a sketch of the palaeology in the time
during which the Hemse and Hamra-Sundre (Ludlow) Beds were formed.
Variation is described in the tabulates Favosites hissingeri Edwards
& Haime, F. obliquus (Sokolov), F. gothlandicus Lamarck, F. forbesi
Edwards & Haime, Syringolites kunthianus (Lindstrom), and
Alveolites suborbicularis Lamarck. * In order to clarify ecophenotypic
variation of corallite size in tabulates, the corallite area and three
different corallite diameters were measured. Although the corallite
area is more related to the shape of the organism that lived in a
corallite, comparison of the several parameters revealed that measuring
of a corallite diameter can be applied in such species from which
ecophenotypic variation is known. However, the current limitation of
variability in corallite diameters within defined morphospecies is
often far too narrow, and does not allow for ecophenotypic variation.
As a consequence, the number of morphospecies established since Sokolov
(1950) is unrealistically large in the F. forbesi group as well as in
others. Variability in F. hissingeri is influenced to a high degree by
the environment. The characteristic (genetically controlled?) pattern
of larger corallites between smaller ones in F. forbesi is hardly
influenced by ecological factors. Variation in thickness of the wall,
in distance between the tabulae and in intensity of the development of
the septal structures is mainly determined by the environment.

1451 <SOURCE>Paleont. Contr. Univ. Oslo 278 [D. Worsley(ed.): Field Meeting Oslo Region 1982; IUGS, Subcommission on Silurian Stratigraphy]: 43-53.</SOURCE>
1452 <ABSTRACT>The distribution of Lower Silurian coral faunas in the Oslo Region reflects the shifting depositional environments represented in the succession. Tabulate corals are the dominant fossil group in some rocks, such as the patch reefs of the Rytteraker Formation or the marl banks in the middle of the Vik Formation. They are correspondingly rare in the clastic sequences of the Bruflat Formation. Halysitids occur through most of the sequences, but only represent an important faunal constituent in the shaly intervals. Systematic studies have only been carried out in the Vik Formation, and most illustrations presented here are from this unit. [original summary] </ABSTRACT>

1490 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 91, 1/4: 205-215.</SOURCE>
1491 <ABSTRACT>The type specimens of *Alveolites fougti* Milne-Edwards & Haime 1851, type species of the genus *Planalveolites* Lang & Smith 1939 from the Silurian of Gotland, have been traced (coll. de Verneuil, Université Claude Bernard, Sciences de la Terre, Lyon 1) and a lectotype is designated. Additional material from Lusklint, Upper Visby Beds, Lower Wenlock, permits an accurate description of the morphology and structure of the species and completes the sparse data available from Stumm (1968) and Lafuste (1984) (new data on the "epithec", on the bilateral symmetry of the septal ridges on the upper margin of the calice, on the tabulae seen in longitudinal transverse and tangential sections). Increase is lateral, but secondary thickening of the wall often makes it look like intramural. Standard and ultra thin sections from an unfigured fragment of the lectotype show the scutellate microlamellae described by Lafuste (1984). The specimens of *Planalveolites* from Lusklint show a great variability in size and sometimes in calice morphology, and the attribution of all the coralla to *P. fougti* is discussed. The species assigned to the genus are also discussed.</ABSTRACT>

1503 <SOURCE>GFF Geologiska Föreningens i Stockholm Förhandlingar 100: 53-63.</SOURCE>
1504 <ABSTRACT>The shell ultrastructure of six aulopoid coral species was investigated and shown to have originally been constructed of laminar calcite. The mineral succession begins with a subcuticular granular layer and continues with a secondary laminar layer which makes up the

- bulk of the skeleton. The laminar layer is constructed of lath-like crystals 2-4µm thick and 10-20 µm wide, and is penetrated by granular rods which originate from the primary granular layer and protrude into the calicular cavity as spinose septa. The lamina deflect around the granular rods in an inward convex pattern. The following species were studied: *Aulopora amiea* Klaamann 1962, *Aulopora neosopina* Klaamann 1966, *Syrinsopora schmidti* Chernyshev 1937 (all from Ludlow of Gotland), *Syrinsopora multifaria* Klaamann 1962, *Syrinsopora blanda* Klaamann 1962 (Ludlow of Estonia) and *Syrinsopora* sp. 1568 <SOURCE>Izv. AN Estonskoy SSR, Geol. 27, 2: 53-58.</SOURCE>
1569 <ABSTRACT>Auf Grund der taxonomischen Revision wurde die stratigraphische Verbreitung - Oberes Llandoveryum - Unteres Wenlockium - der bisher nur aus erraticischem Material bekannten Catenipora quadrata bestimmt. Aus dem Oberen Visby-Mergel von Gotland, wo die Art am haeufigsten vorkommt, hat man den Neotypus gewaehlt. Die durchgefuehrte Revision stellte die synonymischen Arten und die Veraenderlichkeit der Form und Groesse der Ketten und Koralliten fest. In korrigierter Form lassen sich die wichtigsten Merkmale von C. quadrata zu folgender Diagnose zusammenfassen: Catenipora mit kleinen Koralliten 0,75-0,9 x 1,0-1,2mm im Durchmesser. Da die Korallitenwand an den Seiten ziemlich flach ist, erscheinen die Koralliten etwas eckig, insbesondere an der Oberflaeche des Stockes und wo die Waende duenner sind. Die Boeden duenn und wellenfoermig, Intervall 0,15-0,5mm. Septaldornen zonal zahlreich entwickelt, lang und in der Mitte der Koralliten zu einer unterbrochenen Kolumnella vereinigt. [morphology and geological age of Halysites catenularius; in Russian
with English summary]</TITLE>
1581 <SOURCE>Izv. AN Est. SSR, Geol. 28: 140-144.</SOURCE>
1582 <ABSTRACT>The author presents a description of the Halysites genotype,
based on the research into the neotype and on the revision of
halysitids of the Gotland Silurian. The stratigraphic distribution is
limited to the Llandoveryan stage of the Lower Silurian whence also the
finds made in Gotland (Lower Visby marl) and those of species
considered synonymous with Halysites catenularius (see the synonymies)
in other regions. The diagnostical characters of the species are as
follows: meshes outstretched, of varying shape; consist of corallites
of 1.3-1.5mm in width and 1.6-1.8mm in length. Mesocorallites mostly
rectangular, 0.5-0.6 x 0.75mm, the joints of meshes irregularly
triangular or polygonal. Corallite wall 0.15-0.2mm thick, consists of
uniform, finegrained calcium carbonate. Septa moderately developed,
constantly 12 in number. Tabules horizontal, slightly concave or
convex, placed at an interval of 0.4-0.7mm; mesocorallites are twice as
densely diaphragmed. A comparison of the quantitative characters of
Halysites catenularius and synonymous species are presented in a Table.

1673 <ABSTRACT>In the Baltic Sea, reef structures are common in the Ordovician and Silurian sedimentary bedrock. Palaeozoic reef development culminated in the Silurian when several successive reef barriers developed. The present investigation has revealed new reef structures in the upper Silurian sedimentary bedrock. Two new biostromes, E1 and E2, have been found in the Ludlovian Eke Beds, east of Gotland. The biostromes trend in a more or less east-west direction and can be traced across the northern part of the Baltic Sea. In the Pridolian, two reef-like barriers, named B5 and B6, occur at the boundary to the Devonian. The lower barrier, B5, is found to the south of the younger B6 barrier. This indicates that a transgression occurred between the formation of the two barriers. A tentative reconstruction of the Pridolian bay suggests that the coast shifted from a more east-west direction in the Ludlovian to a more north-easterly to south-westerly direction in the Pridolian. Bioherms are commonly associated with the Eke biostromes and the upper Pridolian reef-like barriers. The bioherms occur on the seaward side of the larger reef structures, on the biohermal slope. Patch-reefs also occur on the biohermal slope but they are more common on the landward (lagoon) side of the barriers. [original abstract]</ABSTRACT>

1686 <ABSTRACT>Seismic reflection profiling east of Gotland has given information on a succession of four reefal units in the lower Ludlow stratal sequence ranging from the Klinteberg Formation to the Hemse Group in the Gotland sequence. In this paper they are named the Klinte Reef (Klinteberg Formation unit f), the Hammarudden Reef (Hemse Group 'younger' units a-c), the Östergarn Reef (Hemse Group unit d) and the Millklint Reef (Hemse Group unit e). The reef units form a mainly regressive succession with younger reefs resting on the seaward slopes of older reefs. The reef succession is exposed on Gotland and in the Baltic Sea east of Gotland, whereas towards the East Baltic coast it is overlain by Pridoli sedimentary bedrock. Each reef unit corresponds to a well-defined seismic unit with distinct facies zonality ranging from lagoon via reef barrier and biohermal slope to basin facies. The 'fore-reef' facies is in this paper termed biohermal slope to express its characteristic reefal features. Reconstruction of the post-depositional tilting of the sequence indicates lagoonal depths of up to 10m. The reef barriers developed at depths of up to 20m and the biohermal slopes at between 10 and 55m. The reef barrier and the biohermal slope are generally separated by a debris fan of waste products from the reef, 1-2km wide. The reef

barriers are generally 1-3km wide, which is about the same width as their lagoons. The biohermal slopes become successively wider towards the upper part of reef succession, ranging from 5-9km at the Klinte Reef to 15-18km at the Millklint Reef. Comparisons with the Gotland sequence show that the reef barriers are biostromal stromatoporoid reefs in a matrix of crinoid debris. The biostromes are of the Kuppen type. The bioherms are of the Axelro and Hoburgen types. The bioherms occur randomly on the seaward slope of the barriers. [original abstract]

- 1736 <TITLE>The Formation of Micritic Limestones and the Development of Limestone-Marl Alterations in the Silurian of Gotland, Sweden.</TITLE>
- 1737 <SOURCE>Facies 34, 1: 159-176.</SOURCE>
- 1738 <ABSTRACT>Micritic limestone-marl alternations make up the major part of the Silurian strata on Gotland (Sweden). Their position on the stable Baltic shield protected them from deep burial and tectonic stress and allowed the preservation of early stages of burial diagenesis, including lithification. In the micritic limestones certain characteristics have been preserved (e.g., pitted microspar crystals, sharp boundaries between microspar and components, lack of deformation phenomena) that offer insights into their formation. We suppose the formation of these micritic limestones and limestone-marl alternations to be based on a rhythmic diagenesis within an aragonite solution zone (ASZ) close below the sediment surface. The micritic limestones are the product of a poikilotopic cementation of carbonate muds which consisted of varying portions of aragonitic, calcitic and terrigenous matter. Their microspar crystals show the primary size and shape of the cements lithifying the original carbonate mud. Dissolution of aragonite in the marls provided the carbonate for the lithification of the limestones. By cementation, the limestone beds evaded further compaction. The marls, which already underwent a volume decrease by aragonite depletion, lacked cement and became more and more compacted due to increasing sedimentary overburden. Although field observations show that primary differences in material influence the development of limestone-marl alternations they are not required for their formation.</ABSTRACT>

- 1751 <ABSTRACT>The Silurian (Wenlockian-Ludlovian) carbonate sequence of Gotland includes numerous reef-like constructions formed on a warm, shallow and open marine shelf. They were often exposed above sea-level in their depositional time. The constituents of the reef-like limestones were quantitatively analysed. The most important reef-building organisms were stromatoporoids for all the investigated limestones. However, the limestones in the upper part of the Gotland sequence show stronger domination by stromatoporoids and higher stromatoporoid density on the rock surfaces than the limestones in the

Lower sequence show. The most important identifiable sediment producers were echinoderms, with the exception of one example from the Hogklint Formation in which calcareous algae dominated. The investigated reef-like limestones vary as to stages of maturity. Only one of the limestones (Holmhällar 1) can be strictly regarded as a reef limestone. The other investigated limestones exhibit no or poorly developed frameworks. Important conditions for the development of the Gotland reefs were the formation of a stable bottom associated with karstic processes, low sedimentation stress, and domination by stromatoporoids as a condition for faunal capacity in constructing frameworks. This last condition may have been dependent on the stages of global evolution of the Palaeozoic reef community.</ABSTRACT>

1840 <TITLE>Upper Devonian (Frasnian) corals (Anthozoa) of Belarus. Part 1: systematic composition, stratigraphic distribution, palaeoecology.
</TITLE>
1841 <SOURCE>Lithosphere 2, 29: 49-60.</SOURCE>
1842 <ABSTRACT>The present paper describes the taxonomic composition, stratigraphic distribution and palaeoecology of Upper Devonian (Frasnian) Rugose and Tabulate corals (Anthozoa) of Belarus. Corals are widely distributed in carbonate rocks of the Pripyat Trough, Zhlobin Saddle and Orsha Depression, being especially abundant in the Buinovichi beds (Semiluki Formation, Middle Frasnian) and Ptich beds (Voronezh Formation, Upper Frasnian). * The following species have been recognized from the Semiluki Formation: *Aulopora schelonica aseptata* Zaika, subsp.nov., *Thamnopora cervicornis* (Blainv.), *Th. polyforata* (Schloth.), *Th. reticulata* (Blainv.), *Th. tumefacta* Lec., *Gracilopora vermicularis* (McCoy), *Scoliopora conferta albaruthenica* Zaika, subsp.nov., *Crassialveolites obtortus* (Lec.), *Cr. domrachevi* (Sok.), *Alveolites suborbicularis lamellosa* Lec., *Planocoenites medius* (Lec.), *Disphyllum pashiense* (Soshk.), *D. kostetskae* (Soshk.), *Thamnophyllum monozonatum* (Soshk.), *Pterorrhiza multizonata* (Reed) and *Pt. berdensis* (Soshk.). Another association consisting of *Peneckiella jevlanensis* (Bulv.), *P. achanaiensis* Soshk., *P. szulczewskii* Rózk., *P. fascicularis* (Soshk.), *Aulopora soshkinae* Sok. and *Aulocystis tikhyi* Sok. is known from the Voronezh Formation. * It may be supposed that the majority of species mentioned above penetrated into Frasnian epicontinental basins of Belarus during Middle and Late Frasnian time through the seas of the Main and Central Devonian Fields, and, possibly, through the basin of the Doniets-Dnieper depression. Two local subspecies of *Aulopora schelonica aseptata* Zaika, subsp.nov. and *Scoliopora conferta albaruthenica* Zaika, subsp.nov. are indicative of some isolation of Frasnian faunas of the Pripyat Trough. * Different kinds of coral biofacies are typical of the Buinovichi and Ptich beds. Coral communities of Buinovichi time in the Pripyat Trough inhabited hard-bottom upfolds and formed tabulate-stromatoporoid buildups like biostromes and caliptras of several tens of centimetres thick. Ramose tabulate and rugose corals populated soft-bottom depressions. Coral-stromatoporoid buildups were much bigger in size in the Zhlobin Saddle and Orsha Depression, which may suggest the more dissected relief of the sea bottom as compared with that of the Pripyat Trough. Also, massive cerioid colonies of unidentified rugose corals contribute significantly to coral-stromatoporoid organogenic building in the Orsha Depression. * Communities of fasciculate rugose corals and auloporoid tabulates inhabited soft-bottom surfaces in the Pripyat Trough during Ptich time. [original English summary]</ABSTRACT>

Description of taxons.</TITLE>
1906 <SOURCE>Lithosphere 1, 30: 57-74.</SOURCE>

- 1907 <ABSTRACT>This paper is the second part of the research into the Upper Devonian (Frasnian) corals of Belarus. Twenty five species and subspecies of the Tabulate and Rugose corals have been described and illustrated from the Middle-Upper Frasnian of the Pripyat Trough, Zhlobin Saddle and Orsha Depression for the first time. Two new subspecies identified may suggest some isolation of the fauna of the Frasnian Pripyat Paleobasin. Some major zoogeographical and paleoecological implications were outlined in the first part of the paper. [original English summary; the list of species is almost the same as in Zaika et Kruchek (2008), with few exceptions: (1) *Thamnopora polyforata* (Schloth.) has been only figured, but without description; (2) one more subspecies *Alveolites suborbicularis suborbicularis* has been listed with mentioning its locality, but it is neither described nor figured; (3) one more species, namely *Ivdelephyllum?* sp. should be added to the second association from the Voronezh Formation] </ABSTRACT>

- 1919 <SOURCE>Palaeoworld 19, 3-4: 278-283.</SOURCE>
- 1920 <ABSTRACT>Based on the exploratory drilling data provided by LLC LUKOIL-Nizhnevolzhskneft, we studied the structure, composition, and conditions of formation of the middle-upper Frasnian sections of the Pamyatno-Sasovskoye oilfield, Central Russia, which are related to a complex organogenic build-up. We also conducted a lithofacies section modeling based on the data derived from classification of secondary dolomitic limestones (as per Dunham's classification), palaeontological components (e.g., algae, stromatoporoids, crinoids, gastropods, protozoans), structural constructions, and logging data. 2011 <ABSTRACT>Additional data are given here on the taxonomic diversity and distribution of the Carboniferous rugose and tabulate corals of the Donets Basin (Ukraine). Keyserlingophyllum obliquum (Keyserling, 1846) was recorded in the Tournaisian part of the section for the first time. Rotiphyllum omaliusi (Milne-Edwards et Haime, 1851) and Dorlodotia pseudovermiculare (McCoy, 1849) were found in Tournaisian-Visean boundary deposits. Zaphrentes parallelus (Carruthers, 1910), together with Sutherlandia and Cladochonus, was discovered approximately in the mid-Visean. The tabulate coral Volnovakhipora n.gen. from the Tournaisian and the rugose coral Arctophyllum lugankaensis n.sp. from the Gzhelian are established and described.</ABSTRACT>

2050 <ABSTRACT>The type specimen of Diphyphyllum concinnum Lonsdale 1845, which is also the type species of the important Carboniferous rugose coral genus Diphyphyllum, had been thought lost, but one has recently been found again, and is here redescribed. Comparison with recently erected neotypes suggests that they are only doubtfully conspecific. Remarks are given on the history of Murchison's Russian coral collections, which some authors had thought lost, and a list is given of those of his corals held in the British Museum (Natural History) collections.</ABSTRACT>

2076 <ABSTRACT>Ten species and subspecies of colonial Rugose corals (families Palaeosmiliidae and Lithostrotionidae) are described from the Lower Carboniferous of the Donetz basin. From the Visean stage, the zone Cv1d - Diphyphyllum latetabulatum Volk. The zone Cv1f - Palaeosmilina regia Phill., Diphyphyllum fasciulatum latetabulatum Zhizh. subsp.nov., Lithostrotion longiseptatum Vass. sp.nov., Lithostrotion kwangsiense tanaica Zhizh. subsp.nov., Nemistium grandis Zhizh. sp.nov., Orionastraea phillipsi (M&Coy), Solenodendron ramosa Vass. sp.nov. From the Serpukhovian stage, the zone Cs1b - Aulina (Aulina) grandis Vass. sp.nov.; the zone Cs1d - Diphyphyllum carinatum Bik. [original summary]</ABSTRACT>

- 2153 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 107-115.</SOURCE>
- 2154 <ABSTRACT>Actinocyathus floriformis and A. crassiconus migrated to the Moscow Basin at the beginning of the Aleksin and Mikhailov time (latest Visian) respectively. They gave rise to two groups differing in some morphological characteristics, in patterns of evolution and in ecological plasticity. In both groups the most important evolutionary changes took place at the very beginning of the Serpukhovian. The A. crassiconus group evolved in the open sea in the south of the basin and in the current zone in the north-west as well. It reached its acme at the beginning of the early Serpukhovian. The A. floriformis group evolved in the open sea in the south only, but in the early Serpukhovian it colonized a broad spectrum of habitats in the west and north-west also and reached its acme at the end of the early Serpukhovian. Intracolony variability was typical for most species of

Actinocyathus and became especially high every time species dominated in communities. Intraspecific variability could be represented either by a few adaptive modifications with transitions between them or by distinct adaptive norms. It cannot be recognized in species with high intracolony variability, those which are highly specialized or of low abundance.

2244 <SOURCE>Abhandlungen und Berichte für Naturkunde und Vorgeschichte 12, 3: 3-21.</SOURCE>
2245 <ABSTRACT>Pseudobradyphyllum Dobrolybova 1940 is a polycoeliacean genus and a junior synonym of Paracania Chi 1937. Revision based on topotypes and syntypes of the type species (*Zaphrentis nikitini* Stuckenbergl 1888 from the basal Gzhelian stage of the Moscow basin) demonstrates all essential features of *Ufimia* Stuckenbergl 1895 (Plerophyllidae), modified by an amplexoid trend. There are no affinities with *Bradyphyllum* Grabau 1928 (Hapsiphyllidae). Due to intraspecific variation, and if separated from their series of cross-sections cut from one specimen, some sections might be identified as different genera even of several families (*Ufimia*, *Pentamplexus*, *Amplexocaria*, *Allotropiophyllum*, *Rotiphyllum*, *Bradyphyllum*). 2257 <SOURCE>Acta Geologica Polonica 59, 1: 1-37.</SOURCE>
2258 <ABSTRACT>The present paper is the first in a series devoted to the Early Bashkirian Rugosa (Anthozoa) from the Donets Basin. The history of investigation and current status of Early Bashkirian stratigraphy is discussed in the context of the Donets Basin strata. Corals of that time interval are extremely rare worldwide and those from the Donets Basin have never been described in detail. Four of the five species described are new: Rotiphyllum asymmetricum sp.nov., R. latithecatum sp.nov., R. simulatum sp.nov., and R. voznesenkae sp.nov. Two species are left in open nomenclature. The synonymy, species content and critical review of species potentially belonging to the genus Rotiphyllum are reviewed. [original abstract]</ABSTRACT>

2269 <TITLE>Early Bashkirian Rugosa (Anthozoa) from the Donets Basin, Ukraine. Part 2. On the genera Axisvacuus gen. nov. and Falsiamplexus Fedorowski, 1987.</TITLE>
2270 <SOURCE>Acta Geologica Polonica 59, 3: 283-317.</SOURCE>
2271 <ABSTRACT>Five species belonging to two genera: Falsiamplexus Fedorowski, 1987 and Axisvacuus gen. nov. are described in detail and their species content and relationships are discussed. Both genera are perhaps related to Rotiphyllum and were probably derived from it, but relationship of Falsiamplexus to Bradyphyllum Grabau, 1928 cannot be excluded. The new genus Axisvacuus is represented by four species, of which three are new: A. verus (type species), A. extendus and A. semicirculatus. Stratigraphic ranges of species described are compared to the western European and Russian standards (Table 1). Some possible palaeogeographic implications of the occurrence of Axisvacuus postumus (Smith, 1931) and Falsiamplexus reductus Fedorowski, 1987 are briefly discussed.</ABSTRACT>

2282 <TITLE>Some aspects of evolution in the Lonsdaleia (Actinocyathus) crassiconus species-group.</TITLE>

- 2283 <SOURCE>Palaeoworld 19, 3-4: 316-324.</SOURCE>
- 2284 <ABSTRACT>The Actinocyathus crassiconus species-group represents a separate trend of evolution within the rugose subgenus Lonsdaleia (Actinocyathus) (d'Orbigny, 1849). It is distinguished by consistently developed minor septa and by regular axial structures. In the Moscow Basin, this species-group comprises seven species, A. crassiconus (McCoy, 1849), A. lativesiculosus (Dobrolyubova, 1958), A. sarytschevae (Dobrolyubova, 1958), A. subtilis (Dobrolyubova, 1958), A. gorskyi (Dobrolyubova, 1958), Actinocyathus sp. A, and Actinocyathus sp. B. It ranges from the Mikhailov horizon (Brigantian) to the Protva horizon (lower upper Serpukhovian), and is especially characteristic of the Tarusa horizon (lowermost Serpukhovian) in the north-western part of the basin. Evolution in the group took place at the beginning of Mikhailov time and in Tarusa time and showed three trends: (i) increase in corallite size and number of septa; (ii) increase in number of septa and tabularia diameter; and (iii) a wide range of variability in septal number without important changes in tabularia diameter. Lonsdaleia ornata Dobrolyubova, 1958, L. heckeri Dobrolyubova, 1958, and L. longiseptata crassicolumellata Dobrolyubova, 1958 are synonymised with Actinocyathus subtilis, and Lonsdaleia subcrassiconus subcrassiconus Dobrolyubova, 1958 is with Actinocyathus gorskyi.</ABSTRACT>

- 2310 <ABSTRACT>The Bashkirian rugose coral fauna of the Donets Basin from the Homoceras, Reticuloceras and Gastrioceras biozones is analysed in terms of modern ammonoid, foraminiferal and conodont biostratigraphy. Comparison to the Serpukhovian corals of the same area shows a drastic impoverishment in the Homoceras biozone, culminating in the Reticuloceras biozone. Those two biozones should be considered as the main period of turnover from the Lower to the Upper Carboniferous rugosan faunas. The step by step recovery and appearance of younger faunas began with, and was accelerated during, the Gastrioceras biozone. The fauna of the Donets Basin is distinctly different from

that of the adjacent Voronezh, or the Spanish and North African regions in both generic composition and growth form. Except for a single species of the colonial *Lytvophyllum*?, only solitary taxa of both dissepimental and non dissepimental types occur in the Donets Basin. Many of these taxa are new and show primitive characteristics of Upper Carboniferous taxa. The Donets Basin represents environments differing from those in the areas mentioned above and also was one of the main world centers for the appearance of new rugose coral faunas following the *Homoceras-Reticuloceras* biozone crisis. 2321 <TITLE>Lower Carboniferous (Dinantian and Serpukhovian) rugose coral zonation of the East European Platform and Urals, and correlation with Western Europe.</TITLE>

2322 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 298-310.</SOURCE>

2323 <ABSTRACT>A sequence of nine rugose coral zones (six assemblage zones and three interval zones) is proposed for the Dinantian and Lower Serpukhovian of the East European Platform and Urals. Two assemblage zones are recognized in the Tournaisian, the Siphonophyllia-Conilophyllum and Uralinia-Cyathoclisia-Sychnoelasma konincki zones, three in the Visean, the Haplolasma-Sychnoelasma urbanowitschi, Acrocyathus-Dorlodotia and Palastraea-Actinocyathus floriformis-Nemistium zones, and one in the lower Serpukhovian, the Turbinatocania-Actinocyathus borealis-Paralithostrotion zone. They correspond to the upper part of the Tn1b, to the Tn3, V1b-V2a, V2b-V3b β, V3c, and to the Pendleian-Arnsbergian respectively. Interval zones correspond to the Tn2, V1a and V3bγ. All litho-chronostratigraphic sigla are used in the sense of Conil et al. (1990). * Rugose corals are usually considered important but endemic index fossils, and are seldom used for long distance correlations. Intraspecific variability is often overlooked, with the consequence of the establishment of systematically invalid species. A regrouping of these "species" puts a good tool for correlation at our disposal. * The proposed zones can be correlated with the Lower Carboniferous coral zones established in Great Britain, Belgium and South China. Most of the genera, and even some species, upon which zonations of Western Europe rely on, are observed in the Lower Carboniferous of the Central Russia, Urals and Ukraine (Donets Basin). Comparison of rugose faunas of Europe, Urals and South China shows that communication existed between these areas in the Early Carboniferous, and was especially intensive during the late Tournaisian and latest Visean. 2362 <ABSTRACT>The assignment of the species Michelinia rectotabulata Vassilyuk 1960 to the genus Michelinia De Koninck 1842 has been confirmed by the detailed microstructural study of topotypes; the sclerenchyme is composed of undulating lamellae parallel to the granular median lamina, a peripheral fibrous zone is locally developed. The species, coming from the Serpukhovian of the Donetz Basin, counts among the last representants of the genus, which is not recognized with certainty after the Lower Carboniferous.</ABSTRACT>

2438 <TITLE>Biostratigraphy and biofacies of Upper Carboniferous - Lower Permian rugose coral assemblages from the Isfjorden area, central Spitsbergen.</TITLE>
2439 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 365-380.</SOURCE>
2440 <ABSTRACT>Rugose coral assemblages from the Upper Carboniferous-Lower Permian wordickammen Formation of central Spitsbergen are used in combination with microfaunal data and carbonate facies analysis for biostratigraphic correlations and biofacies interpretations. On the Nordfjordne Block in the west, an Upper Carboniferous (late Moscovian) fauna was recovered from the lower part of the Kapitol Member. This assemblage is characterised by abundant cerioid colonies of Petalaxis, fasciculate colonies of Tschussovskenia ?, Profischerina ? and Fomichevella, as well as numerous chaetetid demosponges. Many of the conical coralla are inverted and occur within well-sorted, shallow-water, skeletal grainstones. In the upper beds of the Kapitol Member solitary caniniids and bothrophyllids of Late Carboniferous (Kasimovian-Gzhelian) age are dominant, including Caninophyllum, Cornuphyllum, Gshelia, Amygdalophylloides, Carinthiaphyllum, Fomichevella spp., and tabulate colonies (Roemeripora and Syringopora). The overlying Tyrrellfjellet Member has only a few corals near the base, where there is widespread development of Palaeoaplysina bioherms, and rare Asselian representations of Heintzella, Tschussovskenia and cerioid Kleopatrina are recorded. In the Billefjorden Trough to the East, the Cadelfjellet Member (equivalent to the Kapitol Member) has phylloid algal bioherms near the base (Pyefjellet Beds) with large solitary rugose corals (Cornuphyllum and ?Caninia?) in packstones. These are succeeded by concentrations of ?Caninia? and Fomichevella in skeletal packstones of Late Carboniferous (Kasimovian-Gzhelian) age, within the otherwise sparsely fossiliferous micrites (Black Crag Beds). Skeletal wackestones and packstones near the top of the Tyrrellfjellet Member have abundant cerioid colonies (Kleopatrina (Kleopatrina), Stylostrea and ?Thysanophyllum?), together with solitary rugosans (Bothrophyllum, Gshelia, Timania, Pseudotimania and Siedleckia) of Early Permian (Sakmarian) age. Two main periods of cerioid development are recognised in the corals of the wordickammen Formation. The first occurred in the late Moscovian (=Myachkovian of the Moscow Basin) with a dominance of petalaxids, followed by a later event in the Sakmarian, (age confirmed with fusulinacean and conodont data). The Upper Carboniferous-Lower Permian rugose coral assemblages from central Spitsbergen have strong affinities with those of the western part of Russia (Urals, northern Timan, Moscow Basin) and the Sverdrup Basin, Arctic Canada and in the late Moscovian form part of the Uralo-Arctic Province. This province can be distinguished from the Mediterranean Province to the south and the isolated coral faunas from California in the west and Japan to the east. Later in the Early Permian the coral faunas from Russia, Spitsbergen, Canada and the western USA form the ?circum-Pangaea? faunal realm.</ABSTRACT>

2477 <TITLE>Carboniferous-Permian corals from Skansen and Festningen, Central Spitzbergen: their faunal characteristics.</TITLE>
2478 <SOURCE>In Nakamura K. (ed.): Investigations on the Upper Carboniferous-Upper Permian Succession of West Spitsbergen 1989-1991; Publ. Hokkaido Univ. Sapporo: 59-75.</SOURCE>
2479 <ABSTRACT>Successive marine Carboniferous-Permian strata containing fossil corals are widely distributed in Spitsbergen, providing some of the best reference areas in the Boreal province. Since Toula (1875) first described two species of rugose corals from the Nordenfjorden, several palaeontological works have been published (e.g., Holtedahl 1913; Heritsch 1993; Padget 1954; Fedorowski 1965, 1967, 1975; Tidten 1972; Birkenmajer & Fedorowski 1980; Nowinski 1982). Among them, Heritsch (1939) first clarified the overall faunal characteristics of the Carboniferous and Permian corals in Spitsbergen. A series of studies by Fedorowski (e.g. 1965, 1967, 1975) mainly focused on the Late Carboniferous to Early Permian from the Hornsund and Bellsund areas. Tidten (1972) described the Carboniferous and Permian Rugosa mainly from the Isfjorden. "Middle to Late" Permian Corals of the Boreal province have not been fully described as to their detailed lithostratigraphic and biostratigraphic data. This report provides a

- brief account of the Carboniferous to Permian coral fauna of the Nordenskiöldbreen Formation at Skansen and the Permian fauna of the Kapp Starostin Formation at Festningen in Central Spitsbergen. Their faunal characteristics are also briefly discussed. The Nordenskiöldbreen Formation is overlain by the Gipshuken Formation. The Kapp Starostin Formation represents the Uppermost Palaeozoic strata observed in Spitsbergen. The Formation overlies the Gipshuken Formation and is paraconformably overlain by the Lower Triassic Vardebukta Formation. For a lithologic and stratigraphic explanation of the Nordenskiöldbreen and the Kapp Starostin Formation, see Nakamura et al. (1987 1990) and in the preceding chapter of the volume mentioned and edited by Nakamura.</ABSTRACT>

2490 <TITLE>Morphogenetisch-ontogenetische Untersuchungen an Pterocorallia aus dem Permo-Karbon von Spitzbergen.</TITLE>
2491 <SOURCE>Palaeontographica A139, 1-3: 1-63.</SOURCE>
2492 <ABSTRACT>On the occasion of two stays in Spitzbergen during the summers of 1960 and 1961, a rich fauna of Corals from the Permo-Carboniferous deposits was collected. It was studied with the aim of revising and completing previous explorations. From the large amount of processed material, only those specimens were selected, in which modern morphogenetic analysis had led to new results. This analysis includes particularly: 1. the structure is the centre of the corallite of those genera which have a constantly or temporarily elongated counter septum, 2. the secondary thickening of the structural elements (previously called "stereoplasma"), particularly considering the reasons for their formation and their degeneration during the course of the ontogeny and 3. the fossula development. The results have been possible due to newly developed methods for thin sections, etching and preparations. Thus, the additional knowledge, presented in the systematics section, has led to a better identification of the characteristics and to a more sophisticated classification. The genus *Sassendalia* with the species *S. turgidiseptata* as well as the species *Pseudotimania latifossulata* are new. Furthermore, the following species are analysed: *Bothrophyllum conicum* Trautschold 1879 sensu Dobroljubova 1937, *B. conicum robustum* Dobroljubova 1940, *B. pseudoconicum* Dobroljubova 1937, *Gshelia rouillieri* Stuckenberg 1888 sensu Dobroljubova 1940, *Timania schmidtii* Stuck. 1895, *Pseudotimania mosquensis* (Dobrolj. 1937), *Caninophyllum calophylloides* (Holstedahl 1913), *Yuanophyllum* sp., *Campophyllum kiaeri* Holstedahl 1913, *Lithostrotion* (*Siphonodendron*) affine (Martin 1809).</ABSTRACT>

2517 <SOURCE>Palaeontologia polonica 43: 17-68.</SOURCE>
2518 <ABSTRACT>Field observations made in 1975 supplement existing data and make possible a new interpretation of depositional environments of the upper Treskelodden beds. It is demonstrated that the entire coral fauna in all "Coral Horizons"; represents re-deposited assemblages. Transportation in some cases was sufficient to abrade and round individual colonies; others were simply overturned from growth position. The upper Treskelodden beds were deposited in very shallow marine environments although some beds and parts of the studied area may have been temporarily exposed above sea level. Environmental changes observed are developed on a local scale only. Tectonic factors are interpreted herein as causing the faunal and sedimentological variations observed rather than the global climatological mechanisms suggested by earlier workers. This interpretation is supported by the small scale and character of the sedimentological variations observed.</ABSTRACT>

2583 <ABSTRACT>The rugose corals from the topmost part of the Kapp Starostin Formation on the Treskelen Peninsula, South Spitsbergen, are described. The collection consists of 22 specimens, representing the genera Calophyllum, Allotropiochisma and Euryphyllum. These solitary and non-dissepimented taxa, considered to be cold-water forms, are representatives of the Calophyllum Province of the Cordilleran-Arctic-Uralian Realm, and confirm a biogeographical connection between Alaska, Ural Mts., Central European Basin, Sverdrup Basin, and Arctic Canada in the Middle Permian. In southern Spitsbergen the Kapp Starostin Formation yields apparently the latest representatives of the Rugosa in the whole Hornsund region, dated to the Guadalupian and probably to the Wordian.</ABSTRACT>

- 2608 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 381-388.</SOURCE>
- 2609 <ABSTRACT>Marine Permian successions, containing various kinds of invertebrate fossils, are distributed widely in Spitsbergen. The Kungurian to Tatarian Kapp Starostin Formation is the uppermost Palaeozoic unit and is characterized by a cold-water fauna dominated by brachiopods, bryozoans and sponges. Non-dissepimented solitary Rugosa also occur, especially in shallow-water carbonates. The coral fauna is entirely different in composition and diversity from that of the underlying Nordenskioldbreen Formation, which was deposited in tropical and / or subtropical conditions. However, similar cold-water faunas are commonly found in contemporaneous formations in other present day Arctic regions such as Greenland and the Canadian Arctic, belonging to the same faunal province. Almost the same faunal succession appeared throughout this province during a climatic cooling characteristic of the Arctic region. The abundance of corals decreases upwards in the Kapp Starostin Formation, showing a strong facies dependence on a local scale. The cold-water, solitary Rugosa disappeared earlier than the other level-bottom organisms, and the warm-water adapted Rugosa in the Tethys. The fauna was primarily affected by a climatic cooling, but was also diminished by various factors of sea-level, tectonic, geochemical and biological origins on local and global scales.</ABSTRACT>

2633 <TITLE>Early Permian solitary rugose corals from Kruseryggen (Treskelodden Fm., Hornsund area, southern Spitsbergen).</TITLE>
2634 <SOURCE>Geologos 15, 1: 57-75.
<http://www.geologos.com.pl/geologos15.html></SOURCE>
2635 <ABSTRACT>A collection of solitary rugose corals collected from the Treskelodden Formation of the Kruseryggen Hill, Hornsund area, south Spitsbergen, consists of 30 specimens representing the Bothrophyllidae family with the genera Bothrophyllum, Caninophyllum, Hornsundia, and Timania (5 species), and an indeterminate family with the genus Svalbardphyllum (one species). These large, dissepimental forms, dating from the Early Sakmarian (Tastubian), indicate a warm-water environment. The lithology, the thickness of the succession, the reddish hue and the abrasion of the fossils indicate that the area of the inner Hornsund showed a relief that enabled considerable erosion of the elevated areas and redeposition of the fossils at remote locations. The changing morphology of this area during the Early Permian was probably influenced by synsedimentary block tectonics. [original abstract]</ABSTRACT>

2672 <TITLE>Kapp Starostin Formation in Spitsbergen: A sedimentary and faunal record of Late Permian palaeoenvironments in an Arctic region.</TITLE>
- 2673 <SOURCE>Mem. Canadian Soc. Petrol. Geol. 17: 647-655.</SOURCE>
2674 <ABSTRACT>The Kapp Starostin Formation is the uppermost Palaeozoic stratigraphic unit in Spitsbergen, ranging from Kungurian to the Tatarian. It contains a cold water adapted fauna dominated by brachiopods, bryozoans and sponges. Four depositional facies are recognised in central Spitsbergen: 1) a cold water carbonate facies on the shallow shelf; 2) a terrigenous sand facies on the deep shelf; 3) a siliceous mud facies on the deep shelf and slope; and 4) a black mud facies in the basin. The cold water carbonates with a limited fauna contain rare non-skeletal carbonate components and carbonate muds and were deposited on a shallow carbonate shelf. The siliceous mudstones, containing numerous sponge spicules, were deposited below normal wave base. At the same depth terrigenous sands with glauconite were distributed in places. The black mudstones are characterised by rare benthic fauna and less bioturbation, implying deposition in a stagnant condition. The sequence of the Kapp Starostin Formation shows four cyclic facies successions, with several transgressive-regressive couplets from shallow carbonate facies to terrigenous sand, deep siliceous or basinal mud facies and vice versa. The whole sequence comprises one transgressive-regressive cycle commonly observed in the Arctic region. The organisms of the Kapp Starostin Formation vary in abundance and taxonomic diversity, showing a strong facies dependence. The faunal diversity decreases with increase in water depth and terrigenous sediment content. The Permian fauna shows strong faunal similarities in composition within Arctic and peri-Gondwana regions and flourished temporarily in a colder climate in the northern hemisphere. The fauna, however, disappeared in a tectonic framework established in the mid-Permian. Relative sea level fluctuations coupled with local and regional tectonism induced a marked variety of adverse conditions for the cold water organisms.</ABSTRACT>

2751 <SOURCE>Journal of Paleontology 79, 1: 21-28.</SOURCE>
2752 <ABSTRACT>A new lyssacinosan hexactinellid, Rossella bromleyi n.sp., is described from the Upper Cretaceous of Arnager Pynt, Bornholm (Denmark). The sponge shows a cup-shaped form with a broad, moderately dense root tuft, which contains three- and four-rayed, orthotropical anchors characteristic for Rossella. The skeleton is composed of bundles of diactines, hexactines of two orders, and pentactines. Diactine bundles are mainly in the growth direction or diagonal to it. Hypodermalia are pentactines with the paratangential rays protruding beyond the outer surface of the sponge body.</ABSTRACT>

2777 <SOURCE>FC&P 9, 2: 11.</SOURCE>
2778 <ABSTRACT>Mid-Cretaceous Scleractinians from Denmark are very few and are known only from outcrops on the island of Bornholm (stratigraphy summarized by Christensen 1978). They have now been revised, and the results are given here. * Upper Albian : gen. & sp. indet. (oculinid ?); gen. & sp. indet. (discoid-patellate); gen. & sp. indet. (1 or 2 species, turbinate-subcylindrical). (The material was

- earlier recorded by Ravn, 1925 (p.21), who also found it to be badly preserved and hardly determinable remains). * Lower and/or Middle Cenomanian: *Micrabaoia* cf. *coronula* (Goldfuss 1826). (The material was recorded as *M. coronula* by Ravn 1916 (p. 14-15).). * From the Late Coniacian Arnager Limestone (also on Bornholm), that for a long time was referred to the Upper Turonian, *Parasmilia fittoni* Edwards & Haime (1850) is known (already recorded by Ravn 1918 (p.18). 2802 <TITLE>The Danian (Paleocene) Coral Limestone of Fakse, Denmark: A Model for Ancient Aphotic, Azooxanthellate coral Mound.</TITLE>
2803 <SOURCE>Facies 22: 103-138.</SOURCE>
2804 <ABSTRACT>The Danish-Polish Trough - a northwest to southeast striking basin - is bordered by the Fennoscandian Shield in the north and the Ringkobing-Fyn High in the south. During the Late Cretaceous and the Early Tertiary carbonate sedimentation prevailed. Locally small bryozoan mounds were formed during the Upper Maastrichtian. The bulk of bryozoan bioherms originated during Danian B to C. Coral communities and coral mounds are confined to the Danian C. About five coral limestone localities occur within the Danish-Polish Trough; Fakse is the most important one. Paleontological and sedimentological data of the coral limestones point to the interpretation of the coral reefs as cold- and deep-water coral bioherms. Important criteria are the (1) absence of algae, (2) low-diverse azooxanthellate coral community, (3) dominance of dendroid growth forms in the corals, (5) occurrence of pelagic organisms (globigerinid foraminifera, coccoliths) within the micrite of the mound facies and intermound facies, (6) breakdown of framebuilders predominantly by bioerosion instead of mechanical destruction, (7) mound- or bank-like structure of the buildups, (8) occurrence at a high paleolatitude. Three major facies types can be distinguished: (1) bryozoan limestones, (2) transitional facies, and (3) coral limestones which include five subfacies types defined by the predominating coral taxa. Most coral mounds are composed of facies types 2 and 3. Diagenesis is characterized by the formation of early marine-phreatic fibrous and bladed cements and by late diagenetic meteoric-phreatic dog-tooth cements and the replacement of calcite cements by quartz. The mounds have an asymmetrical shape caused by unidirectional currents from the south. The maximum length is 200 m, the height 30 m and the width 80 m. The distribution of colonial corals within the mounds indicates a zonation pattern. Framebuilders are

- represented only by azooxanthellate organisms: Colonial scleractinian corals, stylasterine hydrozoans and octocorals. Scleractinian corals have dendroid and arborescent growth forms, whereas hydrozoans and octocorals form fan-like colonies. Strong bioerosion of the framebuilding organisms was responsible for the breakdown of the skeletons; the bioclasts formed the substrate for other framebuilders. The soft bottom between the framebuilders was burrowed by bivalves and crustaceans. The comparison with coral mounds occurring in the eastern Atlantic at similar latitudes and in a position comparable with that of the Paleocene Danish-Polish Trough suggests a paleo-depth between 100 and 300 m. </ABSTRACT>

2816 <SOURCE>Archiv für Geshiebekunde 1, 6: 359-368.</SOURCE>
2817 <ABSTRACT>A geschiebe (= glacial erratic boulder) of Fakse limestone (Danian, Lower Paleocene) from near Hamburg yielded stylasterids (Cnidaria: Hydrozoa) which represent the first finding of fossil stylasterids from Northern Germany and geschiebes. The studied piece of deep water-coral limestone is of the type well known from the quarry of Fakse on the Danish island of Sealand and is presumed to originate from the Baltic area east of that island. The stylasterid fauna comprises 4 species of 4 genera (Congregopora, Errina, ? Stylaster, ? Pliobothrus). All these forms were already known from the quarry of Fakse. In this early stylasterid fauna (the group is known since the Cretaceous / Tertiary boundary) Congregopora is the only genus that did not survive to the present.</ABSTRACT>

Framebuilders are represented only by azooxanthellate organisms: colonial scleractinian corals, stylasterine hydrozoans and octocorals. Scleractinian corals have dendroid and arborescent growth forms, whereas hydrozoans and octocorals form fan-like colonies. Strong bioerosion of the framebuilding organisms was responsible for the breakdown of the skeletons; the bioclasts formed the substrate for other framebuilders. The soft bottom between the framebuilders was burrowed by bivalves and crustaceans. The comparison with coral mounds occurring in the eastern Atlantic at similar latitudes and in a position comparable with that of the Paleocene Danish-Polish Trough suggests a paleodepth between 100 and 300 m. </ABSTRACT>

2842 <SOURCE>Beiträge zur Paläontologie 20: 123-131.</SOURCE>

2843 <ABSTRACT>Penecontemporaneous lithification is shown to be a fundamental part of the construction of the Faxe coral mounds. Internal structures and textural features of the rocks of one of the larger coral mounds exposed in the Faxe Quarry are presented. A close correlation between biological processes and early lithification of interstitial muds, controls both the shape and internal structure of the mounds as well as the textures of the coral limestone. This accentuates a close resemblance between the Faxe coral limestone and recent lithoherms as well as "mudmounds" in general.</ABSTRACT>

2895 <ABSTRACT>The thesis deals with a palaeobiological analysis of an
extensive collection of favositid tabulates from the silurian of
Gotland, Sweden. Discussed are: systematic affinities of the Tabulata
(possible interpretation as sponges), morphology of the Tabulata,
environment and quantitative morphology of some Silurian tabulates from
Gotland. * The following genera and species are described: Favosites
hisingeri Edwards & Haime 1851, Favosites obliquus (Sokolov 1950),
Syringolites kunthianus (Lindstrom 1896), Favosites forbesi Edwards
& Haime 1851, and Alveolites suborbicularis Lamarck 1801. [ISBN

2921 <ABSTRACT>In this paper limy Favositidae from the boulder clay of Groningen and siliceous Favositidae from the preglacial sands of the northern Netherlands are studied. The number of species proves to be much greater than was expected; fourteen species of Palaeofavosites, thirteen of Favosites, four of Mesofavosites, two of Priscosolenia, and two of Multisolenia are described. * A redescription of Favosites staringi Martin 1878 is given. The values given in this description are derived from the measurements to the holotype unfortunately thin sections of which cannot be made and to the fragments from the collection of the author.</ABSTRACT>

2958 <TITLE>The Silurian Rugose Coral Genus Entelophyllum and Related Genera
in Northern Europe.</TITLE>
2959 <SOURCE>Palaeontology 33, 4: 769-821.</SOURCE>
2960 <ABSTRACT>Restudy of Entelophyllum from Gotland (including the type
species) and Great Britain indicates restriction of Entelophyllum to
phaceloid forms with peripheral, parricidal increase. Typical forms
also have smooth or carinate septa, well-developed biserial tabularia,
and dissepimentaria composed of globose interseptal dissepiments. On
Gotland the genus ranges from the late Telychian to the Ludfordian.
Stereoxylodes wang and Carinophyllum Strelnikov are considered junior
synonyms of Entelophyllum. Species from Gotland with nonparricidal
budding are referred to Donacophyllum Dybowski. Cerioid forms
internally similar to Entelophyllum are referred to Prohexagonaria
Merriam. Petrozium Smith is retained for some Early Silurian forms.
Newly described taxa are: Entelophyllum articulatum anglicum
subsp.nov., E. dendroides sp.nov., E. lauense sp.nov., E. hamraense
sp.nov., E. sp. A, Prohexagonaria favia sp.nov., P. gotlandica sp.nov.,
Donacophyllum neumani sp.nov., and D. wallstenense sp.nov.</ABSTRACT>

Carboniferous (uppermost Viséan) of Moscow Basin, and comments on
patterns of variability, evolution and range of the genus in Eastern
Europe and in the British Isles.</TITLE>
2972 <SOURCE>Coloquios de Paleontologia 53: 3-20.</SOURCE>
2973 <ABSTRACT>Studies of variability of Orionastraea from the Moscow
Syncline formerly (Dobrolyubova, 1958) attributes to four species
allow to prove the synonymy of three specific names. The genus is
confined to the upper part of the Aleksin horizon (uppermost Viséan)
and includes two species, O. kurakovensis Dobrolyubova, 1958 restricted
to the southern part of the Moscow Syncline and O. rareseptata
Dobrolyubova, 1958 restricted to its north-western part. The range and
synonymy of the genus are discussed. Patterns of variability based on
examination of Orionastraea specimens from the Coelenterata collections
of the Natural History Museum, London are outlined. Three stages of
evolution of the genus are discerned. Both Russian species appeared
during the first stage.</ABSTRACT>

3024 <SOURCE>Palaeontology 48, 2: 433-445.</SOURCE>
3025 <ABSTRACT>Octocorallian and hydroid fossils are described from the Lower Ordovician (Arenig Series) of Wales. They include gorgoniids that are the earliest known fossils of this group: Petilavenula varifurcata gen. et sp.nov. and P. surculosa gen. et sp.nov. Pennalina crossi gen. et sp.nov. is probably also a gorgoniid but may be a hydroid. A new hydroid, Pontifennia gracilis gen. et sp.nov., is also described.

</SOURCE>
3038 <ABSTRACT>Ordovician Rugosa are abundant in Britain (England, Scotland and Wales), but have not been comprehensively studied recently. They were examined for this study from the viewpoint of faunal composition and provincialism. The Craighead Limestone of the Girvan area, Scotland, contains a fauna of Caradoc age that is marked by the presence of Grewingkia and Streptelasma. However, Lambeophyllum, Paliphyllum, Coelostylis, and Leolasma are conspicuously absent in Scotland. When tabulate corals are also taken into account, the Scottish fauna implies a possible North American affinity and represents a warm water association. The English and Welsh faunas of Ashgill age have been examined at several places, as follows: (1) the Coniston Limestone in the Lake District, northern England; (2) the Conway Castle Grit of Llandudno, as well as the Dolhir Limestone Member of the Dolhir Formation, and the Glyn Limestone of the Glyn Formation, in the Glyn Ceiriog area, North Wales; and (3) the Robeston Wathen Limestone in Robeston Wathen and Whitland, South Wales. These English and Welsh Ashgill faunas contain Bodophyllum, Grewingkia, Helicelasma, Leolasma, Streptelasma, Rectigrewingkia, and Coelostylis. They show a close affinity to faunas from other parts of the East Avalonia Terrane and are also akin to those of Baltoscandia, which constituted the palaeocontinent of Baltica. These two allied faunas may have been strongly influenced by a relatively cold water environment. In contrast, the Laurentian coral fauna differs in composition from the fauna of Avalonia. These faunal differences apparently reflect palaeoclimatic and palaeoceanographic variations, rather than differences in age and terrane. Knowledge of the Late Ordovician rugose corals of Britain, together with palaeoenvironmental studies, is

important for further elucidating faunal migration patterns in terms of the palaeobiogeography of Laurentia, Avalonia and Baltica. [original abstract]

3062 <TITLE>A new scleractinian-like coral from the Ordovician of the Southern Uplands, Scotland.</TITLE>
3063 <SOURCE>Palaeontology 34: 179-194.</SOURCE>
3064 <ABSTRACT>New, discoidal fossils preserved as moulds from the middle Ordovician (Caradoc) of the Southern Uplands are shown to possess characteristic microarchitecture. They are solitary, zoantharian corals with cyclic, hexamerous septal insertion. Successive cycles are arranged in a system of nested triads similar to patterns associated with septal substitution in scleractinian corals. The corallum lacks tabulae or dissepiments but is epithecate with the point of origin of a basal disc as in Scleractinia rather than a cone as in Rugosa. The new coral is named Kilbuchophyllum discoidea gen. et sp.nov., and is placed in the family Kilbuchophyllidae and the new order Kilbuchophyllida. It is interpreted as an early example of skeletal acquisition by the group of anemones that ultimately gave rise to the Scleractinia in the Middle Triassic. The phylogeny of the Zoantharia is briefly discussed in the light of this new material.</ABSTRACT>

3077 <ABSTRACT>New material from the mid Ordovician of Tract 2 in the

- Northern Belt of the Southern Uplands, Scotland, between Biggar and Leadhills extends the range of the coral *Kilbuchophyllia discoidea*. The previous scleractiniamorph interpretation of this species is confirmed and details of septal insertion refined. The shape of the coral is shown to vary between flat and shallowly conical. A new, conical species of the genus, *K. clarksoni* sp.nov., is described, in which the free septal margin may become smooth and a substantial axial structure is developed. It is broadly codistributed with *K. discoidea*. </ABSTRACT>

3114 <TITLE>British Ordovician tabulate corals.</TITLE>
3115 <SOURCE>Monograph of the Palaeontographical Society 157 (620): 144 pp., 3 pls.</SOURCE>
3116 <ABSTRACT>Of the 13 families of tabulate corals represented in the Ordovician successions of South and North Wales, Lake District, Northwest Yorkshire, Cross Fell and Southwest Scotland, three (*Cryptolichenariidae*, *Lichenariidae*, *Paleoalveolitidae*) are exclusive to the Caradoc Series, being the oldest tabulate corals recorded from Britain, five (*Favositidae*, *Proheliolitidae*, *Proporidae*, *Sibriolitidae*, *Taeniolitidae*) are exclusive to the Ashgill Series, while the remaining five (*Billingsariidae*, *Coccoserididae*, *Halysitidae*, *Syringophyllidae*, *Tetradiidae*) are represented in both the Caradoc and Ashgill series. The total known fauna consists of 26 genera, of which *Elkanopora* and *Girvanopora* are new. Of the 63 species and subspecies, two are described under open nomenclature and 25 are new. The

- palaeogeographical distribution of these tabulate corals was affected by the separation of the Laurentia and Avalon palaeocontinents in Caradoc and Ashgill times, the Iapetus Ocean acting as a barrier that prevented the mixing of their coral faunas.</ABSTRACT>

- 3128 <SOURCE>Irish Journal of Earth Sciences 11: 191-196.</SOURCE>
- 3129 <ABSTRACT>The biostratigraphy and palaeobiogeography of the coral faunas of the Lower Silurian succession in the Charlestown inlier, County Mayo, are discussed. Coral faunas are restricted in the fine sandstone lithology of the Cloonnamna Formation, but more common and highly diversified in the Uggool Limestone Member at the base of the formation. The fine sandstones contain the Palaeocyclus porpita - Favosites multipora association, widespread in similar lithologies in the circum-Iapetus area where it is dated as of late Telychian (Lower Silurian) crenulata Biozone age. The Uggool Limestone Member contains 25 identifiable coral species together with 3 stromatoporoids, most known only from one to three specimens. The fauna indicates an early crenulata or possibly griestoniensis Biozone age and contains a mix of species of Laurentian and Avalonian affinities.</ABSTRACT>

- 3141 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 273-281. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
- 3142 <ABSTRACT>Growth-form variation in two British Silurian species of Propora is illustrated using the ternary diagram format of Young & Scrutton (1991). External form is related to an analysis of the internal distribution and angle of growth of corallites and coenenchyme in these corals. The two species are shown to possess quite distinct internal spatial arrangements of corallites which are considered to be genetically determined. Growth-form results from the interaction of these determinative patterns and environmental factors, principally sedimentation. Corallite growth vectors and resultant growth-form are important taxonomic factors in these corals.</ABSTRACT>

3153 <TITLE>A Silurian porpitoïd hydrozoan from Cumbria, England and a note on porpitoïd relationships.</TITLE>
3154 <SOURCE>Palaeontology 47, 5: 1109-1119.</SOURCE>
3155 <ABSTRACT>A porpitoïd hydrozoan, Pseudodiscophyllum windemerensis gen. et sp.nov., from Cumbria, represented by a well-preserved internal float (pneumatophore), is only the fourth porpitoïd reported from Silurian rocks world-wide and the first to be found in any geological formation in England. Its circular pneumatophore is more than 110mm in diameter. Because of the paucity of hard parts, these animals are not common as fossils but may have been important elements of the Palaeozoic oceanic plankton. Although the new species is superficially similar to the Ordovician Discophyllum, there are what appear to be fundamental differences. Similarities to species of Paropsonema, from the Devonian and Silurian, are also probably superficial. The wider relationships of these animals have long been misinterpreted in the palaeontological literature. They are not siphonophores. Correct understanding involves a complete re-interpretation of various homologies and of the evolutionary history of the group.</ABSTRACT>

3206 <SOURCE>Irish Journal of Earth Sciences 17: 115-121.</SOURCE>
3207 <ABSTRACT>Four stromatoporoid species: Pachystylostroma sp., Petridiostroma cf. simplex (Nestor, 1966), Gerronostroma juveniforme sp.nov. and Eostromatopora ringerikensis (Mori, 1978), are described from the Uggool Limestone Member of Cloonnamna Formation (Upper Llandoverly) in the Charlestown Inlier, Co. Mayo, Ireland. A new genus Eostromatopora is established with the type species Stromatopora impexa Nestor, 1966. The fauna described here is closely related to the Telychian stromatoporoid faunas from the Vik Formation of the Oslo area and from the Baillarge Formation of north-western Baffin Island, Canada. - 3245 <SOURCE>Acta Palaeontologica Polonica 25, 3-4: 477-491. </SOURCE>
- 3246 <ABSTRACT>Sporadic dimetrisism in some specimens of two English Wenlock favositid coral species, Favosites multipora and Palaeofavosites rugosa, is investigated by serial sectioning. The diametric appearance is found to be periodically developed within a colony where it occurs and to be caused by fluctuating rates of corallite increase. Peak increase corresponds in a regular pattern to other periodic features in these corals. Zones of close-spaced tabulae, thickened corallite walls and well-developed septal spines form bands of denser growth occurring with an annual periodicity and it is concluded that increase and, therefore, diametrisism is also seasonally controlled in these corals. Entraining factors and the cause of modifications in the relative timing of peak increase are discussed. Diametrisism in these corals is considered to be wholly of ecophenotypic origin and of no taxonomic significance. </ABSTRACT>

- 3258 <SOURCE>Scott. J. Geol. 23, 1: 49-64. </SOURCE>
- 3259 <ABSTRACT>Two new records are described and one previous record reviewed of isolated coral colonies from Llandovery turbidites in the south-west Southern Uplands. Criteria allowing the distinction between modes of origin of such specimens by floatation, bedload transportation and/or reworking are discussed. Two of the specimens, the tabulate corals Propora exigua and P. edwardsi, are interpreted as derived from contemporaneous shelf environments and transported by floatation and

- sinking to their points of interment. The third, a rugose coral *Ceraster* sp., was probably transported in the same way initially, but may have reached its final locus of deposition as part of a turbidite bedload. All three corals are of biostratigraphic or palaeobiogeographic interest. *Propora exigua* is characteristic of the Telychian whilst *P. edwardsi* sensu stricto has only been recorded previously from earlier Llandovery rocks near Girvan. The geographical range of the genus *Ceraster* was hitherto restricted to Asia. </ABSTRACT>

3270 <TITLE>Mass mortalities on an Irish Silurian seafloor.</TITLE>
3271 <SOURCE>Journal of the Geological Society 152: 917-922.</SOURCE>
3272 <ABSTRACT>Recurrent deep-water benthic communities, dominated by diverse tabulate corals, colonized soft substrates during the late Llandovery transgression in western Ireland. A number of autochthonous shelly assemblages dominated by brachiopods, corals and crinoids occur in the upper parts of the Kilbride Formation; the highest and most distal levels are dominated by in situ tabulate corals that are mantled by a thin layer of volcanic ash. Most of the coral colonies could cope with limited sedimentation: growth ceased after the volcanoclastic surge. This catastrophic mode of preservation permits an accurate analysis of an early stage of community development in deep-water benthos on a soft Llandovery seabed, periodically swept by volcanoclastic debris. The Kilbride faunas have implications for the palaeoenvironments and taphonomy of deep-water marine faunas associated with areas of active volcanism. [original abstract] </ABSTRACT>

- 3376 <ABSTRACT>Rugose coral assemblages from the late Tournaisian and early Visean of the Dublin Basin appear to be strongly influenced by water depth and lithofacies, associated with the evolution of a carbonate ramp. This ramp later evolved into a deep-water basin flanked by shallow-water platforms. Shallow-water shelf assemblages in the late Tournaisian are characterised by low-diversity non-dissepimented taxa. These pass up into high-diversity assemblages dominated by large, dissepimented solitary rugose taxa (*Caninophyllum patulum*, *Cyathodisia modavensis*, *Siphonophyllia* sp. A), which colonised deeper-water slope settings on a carbonate ramp. In the latest Tournaisian deep-water waulsortian mudbank limestones supported a sparse coral assemblage, but locally abundant caninioids with rare *Siphonophyllia cylindrica* are recorded. An influx of terrigenous sediment into the Basin during active tectonism, caused suppression of carbonate sediment and only a low-diversity assemblage survived. However, on the flanking shallow-water platforms an abundant high-diversity rugose fauna (*Sychnoelasma urbanowitschi*, *Axophyllum simplex*, *Koninckophyllum cyathophylloides*, *Palaeosmia murchisoni*, *Carruthersella compacta*) became established in the early Visean. Rugose coral biozones can be recognised in the Basin similar to those in western Europe and compliment foraminiferal and conodont biozonations.</ABSTRACT>

</TITLE>
3388 <SOURCE>Trans. Proc. Palaeont. Soc. Japan N.S. 81: 1-10.</SOURCE>
3389 <ABSTRACT>The purpose of this article is to mention the present status
of the Fleming's material of Lower Carboniferous Corals (Royal
Scottish Museum, Edinburgh) in order to establish and to interpret
Fleming's old species. Lectotypes of some species are chosen. The
following Fleming's species were examined: Lithostrotion
striatum, L. floriforme, L. marginatum, Caryophyllia fasciculata, C.
duplicata, C. juncea, Siphonodendron affine, Turbinolia fungites,
Porites cellulosa, Tubipora catenata, T. ramulosa, T. radiatus,
Favosites depressus</ABSTRACT>

3400 <TITLE>The Lower Carboniferous Coral environments of Derbyshire and
adjacent areas.</TITLE>
3401 <SOURCE>The Mercian Geologist 4, 2: 81-95.</SOURCE>
3402 <ABSTRACT>A comparison is made between recent and Lower Carboniferous
coral faunas from morphological and stratigraphical aspects. The
environment of recent corals is summarized and comparisons and
contrasts made of this environment with that of the Lower
Carboniferous, deduced from a study of Derbyshire rocks and fossils. It
is considered that the Lower Carboniferous corals lived in an
equatorial warm water marine environment developing mainly as patch
reefs, just below sea level, with an associated fauna. Outer barrier
reefs, knoll limestone, possibly controlled by abundant crinoid growth,
with or without algae and generally devoid of coral, separated the
coral patch reefs from the surrounding deeper water. Land areas would
be restricted to small, low islands lying to the south, the remnants of
an earlier more extensive St. Georges Land. The possibility that the
main Derbyshire limestone area subsided as a result of an ancient
volcanic platform, floundering, allowing the accumulation of over 2,500
feet of limestones, is investigated.</ABSTRACT>

3439 <TITLE>Development of algal-foraminiferal-coral reefs in the Lower Carboniferous of Furness, Northwest England.</TITLE>
3440 <SOURCE>Lethaia 17: 233-249.</SOURCE>
3441 <ABSTRACT>Most carbonate buildups of Dinantian age are mud-mounds lacking direct evidence of abundant framework organisms. This contribution describes apparently unique structures containing abundant frame-building organisms interpreted as true reefs. They occur in the Red Hill Oolite, part of the Carboniferous Limestone succession in the Furness area of northwest England. Reefs were initiated by the attachment of numerous Syringopora colonies to a firm substrate. Encrusting organisms, dominantly the supposed foraminifer Aphralysia, colonised sediment and corallite surfaces leading to the development of a rigid framework. Thrombolites also assisted in the establishment of bindstone textures. During the later stages of reef growth. Syringopora became less common and its place in the reef was taken by upright, branching growths of solenoporoid algae. Rapid sedimentation and subsidence resulted in reefs with near vertical sides, but little topographic expression on the sea-floor during growth. The occurrence of these reefs cannot be attributed to any single environmental factor but probably resulted from an unusual combination of favourable circumstances. (Original summary)</ABSTRACT>

3453 <SOURCE>Palaeontology 23, 4: 803-820.</SOURCE>
3454 <ABSTRACT>A Palaeozoic chaetetid, bearing intramural spicule pseudomorphs, Chaetetes (Boswellia) mortoni sp.nov., is described from the British Dinantian. Spicules are preserved as calcite, pyrite and silica pseudomorphs. Only silica pseudomorphs retain detail of their tylostyle form. Neomorphism locally obliterates the spicular fabric. A primary mineralogy is suggested consisting of an aragonitic calcareous skeleton, with entrapped opal 'A'; spicules. Comparison of morphology and microstructure with extant and fossil sclerosponges indicates a close relationship between this chaetetid and the Ceratoporellida, and support the sclerosponge nature of some Palaeozoic

chaetetids.</ABSTRACT>

3465 <TITLE>Hexaphyllia: a spiny heterocoral from Lower Carboniferous reef limestones in Derbyshire, England.</TITLE>
3466 <SOURCE>Palaeontology 40, 4: 1031-1059.</SOURCE>
3467 <ABSTRACT>Exceptionally well preserved and abundant corallites of Hexaphyllia are recorded from limestones of the Lower Carboniferous Castleton Reef Belt, north Derbyshire, UK. Details of corallite morphogenesis are presented and the growth attitude of corallites is determined. Tabulae curve down at their margins and fuse together to form the tabulotheca. Conversely, spines curve upward and point in the direction of corallite growth. Soft tissue reconstructions infer the presence of polyps sitting exposed upon and totally enclosing the distal tips of the corallites, with polyp lobes extending down their sides. Much of the corallite is therefore regarded as endoskeletal in origin. Rows of spines projecting from between the polyp lobes gave some degree of protection to the exposed polyps. Assemblages of corallites from different positions in the reef show notable differences in morphology. Variations in shape, wall thickness and tabulae spacing are attributed to contrasting growth rates at different positions within the reef. Examination of approximately 1300 corallites from two localities in the reef reveals the presence of a single species, Hexaphyllia marginata (Fleming), which shows considerable intraspecific variation. Systematic studies indicate that criteria used to distinguish Hexaphyllia: species in the past are invalid and that the majority of previously described taxa are junior synonyms of H. marginata. Heterocoral mode of life is discussed in the light of observations made on this species.</ABSTRACT>

- 3493 <ABSTRACT>Upper Viséan rocks in the Kingscourt, Armagh and Cookstown areas of NE Ireland are dated using foraminifera, calcareous algae and rugose corals, and new positions are proposed for the Asbian/Brigantian and early/late Brigantian boundaries. Of particular interest are assemblages of foraminifera and calcareous algae from the Poulmore Scarp section (Kingscourt), which is now recognized as the only section in Ireland to be composed of platform carbonates of latest Brigantian age. This late Brigantian section is correlated with the interval from the Three Yard Limestone to the Great Limestone in northern England.

- 3506 <ABSTRACT>Foraminiferans, calcareous algae and rugose corals from many sections in the Glencar Limestone, Dartry Limestone, Bricklieve Limestone and Meenymore formations in north-western Ireland have been analysed. Results from the fauna and microflora suggest that these formations constitute the early to late Asbian for the Glencar Limestone Formation and lower Bricklieve Limestone Formation (Cf6_₁-Cf6_₂ foraminiferal subzones), and the upper part of the late Asbian for the Dartry Limestone Formation and upper Bricklieve Limestone Formation (Cf6_₃ subzone). The succeeding Meenymore Formation in the studied area is assigned to the Brigantian (Cf6_₄ subzone). Goniatite biozonal schemes established previously for equivalent strata to the east in the Cuilcagh Mountains that are not in harmony with the dating proposed here are discussed.</ABSTRACT>

3608 <TITLE>The coral Fauna of the Holkerian/Asbian boundary stratotype section (Carboniferous) at Little Asby Scar (Cumbria, England) and implications for the boundary.</TITLE>
3609 <SOURCE>Stratigraphy 2005, 2: 167-190.</SOURCE>
3610 <ABSTRACT>Five coral assemblages from the Holkerian-Asbian succession at the stratotype section at Little Asby Scar, Cumbria (England) have been studied. The stratotype section is located near the fault zone, and contact of the Potts Beck Limestone (earlier Asbian) and the Knipe Scar Limestone (later Asbian) is tectonically controlled. The coral fauna of the Limestone bed which defines the base of the Asbian consists of a coral assemblage which does not contain any coral taxa appearing in the Asbian. The first Dibunophyllum, the traditional coral genus for the Asbian-Brigantian, is not known until the overlying Knipe Scar Limestone. However, other coral taxa from the Knipe Scar Limestone are typical of the later Asbian. No coral assemblage can be doubtless assigned to the earlier Asbian. The coral assemblages of the Little Asby Scar proved that the first appearance of Siphonodendron junceum is in the upper Asbian. The distribution of other important biostratigraphic groups, the foraminiferans and brachiopods, support a relocation of the originally defined Holkerian-Asbian boundary. However, the bases of the biozones of the two most abundant groups, corals and foraminiferans, do not coincide; Asbian foraminiferans appear earlier than Asbian corals. The attempt to correlate the Little Asby Scar succession to the Belgian Namur-Dinant basin and its standardized sedimentary sequences based on a simple presence-absence comparison of corals and foraminiferans does not result in a definite correlation. It is evident that the Holkerian-Asbian boundary as originally defined is lithostratigraphic, and that the absence of any biostratigraphic support prevents the use of that level in a chronostratigraphic context. Therefore, after a consensus on the criterion for the base of the Asbian, the stratotype should be relocated to a better exposed section.</ABSTRACT>

3647 <TITLE>The effects of clastic sedimentation on a fasciculate rugose coral from the Lower Carboniferous of Northern England.</TITLE>
3648 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 91, 1/4: 93-97.</SOURCE>
3649 <ABSTRACT>Fasciculate coralla of the rugose coral, Siphonodendron martini (Milne-Edwards & Haime), preserved in life position in soft argillaceous shales within the Arundian (Lower Carboniferous) Ash Fell Sandstone of Cumbria, northern England, exhibit several peculiar features. Corallite diameter is significantly reduced, with a corresponding decrease of the dissepimentarium and in septal member; colony growth form tends towards phaceloid with slender, parallel corallites devoid of lateral budding; and finally, some corallites exhibit rejuvenescence, a feature previously unknown in this genus. It is suggested that all of these features are a result of an increase in clastic sedimentation in this area. The introduction of large quantities of mud onto the coral thicket would also lead to an imbalance in food supply and a reduction in available light, the later inhibiting photosynthesis by endodermal symbiotic algae. This in turn would inhibit the secretion of calcium carbonate, leading to all of the morphological features observed. Growth rate data, already published from this area, lend support to this theory. The resulting stunted corallites are phenotypic homeomorphs of the descendant species,

- Siphonodendron intermedium Poty, *S. irregulare* (Phillips) and *S. pauciradiale* (M'Coy), which appear in the succeeding Hölkerian and Asbian stages. This may help to explain some of the long-held misconceptions surrounding the missing syntypes of *S. irregulare*.

- 3661 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 035-047.</SOURCE>
- 3662 <ABSTRACT>Detailed sampling from two working quarries at Mokeeran and Ardagh, near Kingscourt have yielded locally abundant Upper Visean coral faunas, with several rugose genera and species new to Ireland. Pale grey, thickly bedded, crinoid-rich platform limestones of late Asbian age at Mokeeran have produced 8 rugose coral genera and 16 species. Colonial corals predominate over solitary rugosans by a ratio of 4:1, with most of the solitary corals occurring within a darker, algal-rich limestone interval. Almost two-thirds of all colonial specimens collected are either Siphonodendron pauciradiale or Lithostrotion decipiens in approximately equal proportions. In the coeval massive buildup ('reef') facies at Ardagh, in contrast, corals are sparse with rare Axophyllum, Siphonophyllia, Siphonodendron and Lithostrotion within the >95 m thick buildup. Several solitary genera (Siphonophyllia) are found in both buildup and platform facies, but individual species are restricted to one facies only. In the top 3m of the buildup at Ardagh, however, abundant fasciculate colonial corals have been recovered including Corwenia rugosa and 'Koninckophyllum' cf. volgensis which establish a Brigantian age for the top of the buildup. Cerioid colonies though are rare and suggest unfavourable conditions for colonization. At Rathgillen Quarry, 10km to the south of Ardagh, bedded limestones above a similar buildup at Cregg have yielded the Brigantian coral Actinocyathus floriformis, which is its first reported occurrence in the Kingscourt outlier.</ABSTRACT>

3687 <SOURCE>The Mercian Geologist 5, 1: 1-18.</SOURCE>
3688 <ABSTRACT>Skeletal variation in a number of colonial Rugose corals from the Carboniferous Limestone of Derbyshire is described. The variation is attributed to the presence of corallites representing different stages of ontogenetic development, to genetic variation and the consequent appearance of phylogenetic trends, and to the effects of external environmental controls. Some types of extreme variation may be caused by pathological factors.</ABSTRACT>

3699 <TITLE>A new genus and species of colonial rugose coral from late Tournaisian (Waulsortian) mud-mounds in Ireland: Its ecological associations and depositional setting.</TITLE>
- 3700 <SOURCE>Palaeoworld 19, 3-4: 414-425.</SOURCE>
3701 <ABSTRACT>A new genus and species of fasciculate rugose coral, *Howthia suttonensis* Somerville and Rodriguez, has been recorded from Howth peninsula, County Dublin, Ireland, in Waulsortian mud-mound limestones of upper Tournaisian age. The new colonial genus is characterized by having an axophyllid axial structure, steeply inclined tabellae, and presence of interseptal and lonsdaleoid dissepiments. It evolved probably from a solitary *Axophyllum* by the development of peripheral offsets. This new taxon may have been an ecological pioneer adapting to a specialised niche near the top of a large Waulsortian mud-mound in shallower water than most Waulsortian settings and, as such, may have provided a novel evolutionary opportunity. *Howthia suttonensis* is associated with *Amplexocarinia* and an unusual form of *Fasciculophyllum*, both of which display budding and protocoloniality, as well as the fasciculate tabulate coral *Syringopora*. 3712 <TITLE>Rugose coral biostromes in the late Viséan (Mississippian) of NW Ireland: Bioevents on an extensive carbonate platform.</TITLE>
3713 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 292, 3-4: 488-506.</SOURCE>
3714 <ABSTRACT>The extensive upper Viséan (Asbian) platform carbonates in NW

Ireland (Bricklieve Limestone Fm, Glencar Limestone Fm and Dartry Limestone Fm) contain distinctive rugose coral biostromes, which are dominated by different species of the genus *Siphonodendron*. These are in stratigraphic sequence: pauciradiale biostrome (oldest), martini biostrome and several junceum biostromes (youngest). They represent bioevents caused by special short-lasting ecological conditions and can be used as approximately synchronous horizons to correlate within the region. The pauciradiale biostrome is the thickest, laterally most persistent and most variable in facies and biotic composition of all biostromes. It formed on a tectonically influenced platform with a landward-seaward zonation from northwest to southeast, mainly above storm wave-base and below fair-weather wave-base. The northwestern Streedagh facies is characterized by the presence of clusters of large sheet-like colonies of *S. pauciradiale*. The intermediate O'Donnell's Rock facies is unique for the predominance of the fasciculate genus *Solenodendron*. The southeastern Bricklieve facies represents the amalgamation of autochthonous and allochthonous coral debris and bioclastic debris with localized small patches of coral boundstone. Mass occurrences of fasciculate rugose corals re-appear in the martini biostrome. This biostrome developed in a shallower water setting, just above fair-weather wave-base on a levelled carbonate platform. The junceum biostromes are thinner, decimetre to some metres thick, and less persistent. They formed in deeper water mostly below storm wave-base, except for the composite 2nd junceum biostrome of the Bricklieve Mountains, which records a period of shallowing. According to facies and coral morphologies, which were compared with modern scleractinian growth forms, sea-level variation exerted one of the strong controls on the rise and decline of the biostromes. The pauciradiale biostrome formed during an extended shallowing-upward cycle in a depth interval leading to the climax of *Siphonodendron pauciradiale*. The cycle ended with the development of the martini biostrome in shallow water. Its demise is probably caused by drowning during the late Asbian sea-level rise. During that time slice the junceum biostromes flourished in deeper water on the platform. Coral growth ceased almost completely after formation of the junceum biostromes during the falling sea level of the latest Asbian. Siliciclastic input and resulting turbidity, as well as turbulence formed a complex cascade of ecological constraints. In addition to the local tectonic influences, they combined to result in the depth factor which controlled the distribution of predominating coral populations and the succession of the different biostromes in the Asbian of NW Ireland.

3751 <TITLE>Stratigraphy of Upper Viséan carbonate platform rocks in the Carlow area, southeast Ireland.</TITLE>
3752 <SOURCE>Geological Journal 40, 1: 35-64.</SOURCE>
3753 <ABSTRACT>The stratigraphy of the upper Viséan (Asbian to Brigantian) carbonate succession in southeast Ireland is revised on the basis of seven quarry and two borehole sections. Six lithological units have been distinguished, two units (units 1 and 2) in the upper Asbian Ballyadams Formation, and four units (units 4 to 6) in the Brigantian Clogrenan Formation (both formations are dated precisely using foraminiferans, calcareous algae and rugose corals). The boundary between the Ballyadams and Clogrenan formations is redefined 19 m below the horizon proposed by the Geological Survey of Ireland, and thus, lithological characteristics of both formations are redescribed. The upper part of the Ballyadams Formation is characterized by well-developed large-scale cyclicity, with common subaerial exposure surfaces. Fine- to medium-grained thin-bedded limestones with thin shales occur in the lower part of cycles, and passing up into medium-grained pale grey massive limestones in the upper part. The Clogrenan Formation is composed mainly of medium- to coarse grained thick limestone beds with variable presence of shales; but no large-scale cyclicity. There is a decrease in the number of subaerial exposure surfaces towards the top of the formation and common chert nodules; macrofauna occurs mostly concentrated in bands. The six units recognized in the Carlow area are comparable with other units described for the same time interval (Asbian-Brigantian) from south and southwest Ireland, demonstrating the existence of a stable platform for most parts of southern Ireland, controlled principally by glacioeustatics.</ABSTRACT>

3818 <ABSTRACT>The Asbian mud mounds in of the Sligo syncline in northwestern Ireland have been investigated by applying sedimentological and geochemical methods. The mud mounds were deposited in a deeper shelf setting, water depth was about 200m. They consist of

- micrite and peloidal micrite. Mound builders are siliceous sponges and associated microbes. Carbonate forming the mounds was produced and accumulated in situ via microbial decomposition of sponge soft tissue. Stable isotope fractionation was in equilibrium with ambient seawater. Diagenetic processes changed the sponge images to a point that they are hard to recognize. Stromatactoid cavities were left, if calcification of sponges was incomplete. Radial fibrous cements lining the cavities were precipitated almost syndementarily under marine phreatic conditions. During the transgressive part of the basin history the sponges grew continuously more important. This development finally resulted in the establishment of sponge-microbial mud mounds. </ABSTRACT>

3829 <TITLE>Lower Carboniferous (Dinantian) stratigraphy and structure in the Kingscourt Outlier, Ireland.</TITLE>
3830 <SOURCE>Geological Journal 30: 1-23.</SOURCE>
3831 <ABSTRACT>Logging of 55 recent boreholes, together with remapping, has resulted in a fundamental reassessment of the stratigraphy and sedimentology of the Dinantian Kingscourt Outlier. Despite the present isolated position of the outlier within the Longford-Down Massif, the Kingscourt rocks are an integral part of the Dublin Basin succession. The newly defined Ardagh Platform marks the most northerly limit to basinal sedimentation in the Dinantian Dublin Basin. The Courceyan is a typical but thinner, north Dublin Basin succession with two new formal units: the Rockfield Sandstone Member and the Kilbride Formation. The latter, a coarse-grained, well washed limestone of latest Courceyan to early Chadian (late Tournaisian) age is the shallow water equivalent of the Feltim Formation (Waulsortian facies), which is absent in the outlier. The Courceyan interval in the north of the outlier is markedly attenuated. In the succeeding Chadian-Brigantian interval basinal facies predominate in the south, but on the Ardagh Platform an almost complete coeval Viséan shallow water sequence is found. A new platform unit (Deer Park Formation) of latest Asbian to Brigantian age is defined in the Ardagh area. The Dee Member (Chadian) is newly defined for the lower part of the basinal Tober Colleen Formation and the Altmush Shale Member is formally defined for the upper part of the Loughshinny Formation. Two major structures dominate the Kingscourt Outlier: the NE SW trending Moynalty Syncline in the south and the N-S trending Kingscourt Fault. Both are Hercynian structures, but probably represent reactivated Caledonide basement-controlled structures. Dinantian syndepositional faulting is indicated in both the Courceyan ('Kingscourt Sag') and Chadian-Asbian. The latter period of faulting in the Ardagh area separates platform facies in the north from basinal facies to the south. In the late Asbian, platform facies with carbonate build-ups prograded south into the basin as far south as Nobber, but in the latest Asbian to Brigantian, basinal facies extended northwards over the collapsed platform margin. Foraminifers, corals and conodonts are mentioned with the stratigraphic units.</ABSTRACT>

3842 <TITLE>Bathymetry on a Carboniferous reef.</TITLE>
3843 <SOURCE>Lethaia 06, 4: 367-381.</SOURCE>
3844 <ABSTRACT>In the Lower Carboniferous deposits of Castleton, Derbyshire, well bedded shelf limestones, apparently of shallow water origin, pass northwards into a marginal tract of poorly bedded apron-reef limestones which dip at about 30° downwards and away from the shelf. Geopetal infillings of shell cavities in the apron-reef indicate only minor movement since deposition and the observed dip must be due to deposition on a sloping sea floor. At certain times this sea floor was colonised by stromatolitic algae and corals such as Lithostrotion at the apron-reef crest where there was minimum water depth, followed to progressively increasing depths by a fauna dominated by the coral Michelinia, a fauna of small brachiopods, bryozoa, molluscs, trilobites, and other organisms and a fauna dominated by Pseudamussium. At other times crinoidal debris was the dominant component of the apron-reef, when an alignment of crinoid stems parallel to the dip of the slope occurred at low levels, but a random orientation at the apron-reef crest. Other sediments on the apron-reef are apparently devoid of macrofossils. Volcanic activity occurred during the development of the apron-reef, and it is suggested that uplift of the shelf area preceded the subaerial flow of a lava tongue which reached and plunged down the apron-reef slope and into the sea.</ABSTRACT>

3855 <TITLE>Carbonate facies and biostromal distribution in a tectonically controlled platform in northwest Ireland during the late Viséan (Mississippian).</TITLE>
3856 <SOURCE>Proceedings of the Yorkshire Geological Society 57, 3-4: 165-192.</SOURCE>
3857 <ABSTRACT>The North-west Carboniferous Basin (NWCBS) contains a c. 3 km-thick succession of Mississippian (Courceyan to Arnsbergian) limestone, mudstone and sandstone, mostly of marine origin. The litho- and biostratigraphy of some sections in the basin are revised and new logged sections described in upper Viséan, limestone-dominated platform successions. In the O'Donnell's Rock area, a precise correlation of the Glencar Limestone Formation with the lower part of the Bricklieve Limestone Formation, and the Dartry Limestone Formation with the upper part of the Bricklieve Limestone Formation is confirmed. Consequently, in late Viséan (Asbian) times the NWCBS developed as an extensive (12,000 km²) carbonate platform, in which sediments of the facies typical of outer, middle and inner parts of the platform were deposited. occurring in the British Jurassic.</TITLE>
3895 <SOURCE>Proc. Geol. Assoc. 102, 4: 251-259.</SOURCE>
3896 <ABSTRACT>A list of scleractinian coral species is presented in
stratigraphical sequence through the British Jurassic together with
relevant localities. The information has been drawn largely from 19th
and 20th century literature with some additional museum records.

- 3959 <TITLE>British Jurassic Corals in the literature.</TITLE>
- 3960 <SOURCE>FC&P 04, 2: 34-36.</SOURCE>

- 3961 <ABSTRACT>In the 17th and 18th centuries, there were a number of isolated references to what we know as Jurassic corals, including, of course, the work of Linnaeus (1758-59). The 19th century saw a great deal of interest in British Jurassic corals and a number of collectors and authors turned their attention to this group. Early in the century, Parkinson (1808) described and figured several Jurassic corals in his "Organic Remains". Later came Milne-Edwards and Haime (1851) "A Monograph of the British Fossil Corals" and then Duncan (1872) "Supplement", followed by Tomes (1878, 1879, 1882, 1883, 1885, and 1886). During the century, other authors gave stratigraphical details and made general comments on famous localities and recorded various species. - 3972 <TITLE>The ploughed field habitat.</TITLE>
- 3973 <SOURCE>FC&P 13, 2: 24-27.</SOURCE>
- 3974 <ABSTRACT>There are two Jurassic localities which have become famous for the number of corals ploughed up on certain fields over many years. One is Fairford, Gloucestershire - Great Oolite, (Bathonian) and the other is Steeple Ashton, Wiltshire - Corallian, (Oxfordian). [] There are, of course, some disadvantages to ploughed field material. It is not in situ and unless you are able to dig a trench, the stratigraphy remains uncertain. The corals are subject to dispersal by farming activities and damage by machinery. Also there is the possibility of intrusions, that is, fossils from nearby exposures becoming mixed with the ploughed up material. However, since the basic material of palaeontology is often fragmentary and incomplete as many of you are well aware, I suggest that ploughed fields can be rewarding, despite their drawbacks. [first and last fragments of a transcript of a talk given to the Coelenterate Club at Nottingham University in March 1984; submitted to FC&P by C.T. Scrutton]</ABSTRACT>

3998 <TITLE>Facies and Palaeoecology of Upper Jurassic (Middle Oxfordian) Coral Reefs in England.</TITLE>
3999 <SOURCE>Facies 40, 1: 81-100.</SOURCE>
4000 <ABSTRACT>This study documents the facies and fauna of Late Jurassic (Middle Oxfordian) coral reefs in England. Sedimentological and palaeoecological analysis of these reefs distinguishes three generic reef types: (1) small reef patches and thickets associated with siliciclastic deposits; (2) small reef patches and thickets associated with siliciclastic-free bioclastic grainstones and packstones; and (3) biostromal unites associated with deep water facies. The depositional environments of these reef types are discussed. Two coral assemblages are identified: (1) the microsolenid assemblage; and (2) the Thamnasteria, Isastraea, Fungiastraea and Thecosmilia assemblage (Thamnasteria assemblage). The Thamnasteria assemblage developed in all shallow water environments in the study area, regardless of local environmental conditions. The fauna is very eurytopic, r-selected and can tolerate significant environmental fluctuations on short temporal scales (sub-seasonal). The main control on the development of the microsolenid assemblage was low light intensity, low background sedimentation rates and low hydrodynamic energy levels.</ABSTRACT>

4012 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 014, 4: 293-317.</SOURCE>
4013 <ABSTRACT>The Corallian Beds of southern England consist of 4 asymmetric, upward shallowing cycles. Each cycle is separated from the next by a non-sequence, usually an erosion surface, which marks a marine transgression. Transgression was the result of a sudden rise in sea level, the period of rise being perhaps less than 7000 years. There is evidence of the same non-sequences occurring elsewhere in Britain and abroad, suggesting that the transgressions were the result of world-wide, eustatic changes in sea level.</ABSTRACT>

4024 <TITLE>A probable thecate hydroid from the Upper Cretaceous of southern England preserved by bioimmuration.</TITLE>
4025 <SOURCE>Paläontologische Zeitschrift 62, 3-4: 167-174.</SOURCE>
4026 <ABSTRACT>An inferred thecate hydroid, moulded on the attachment scar of the bivalve Pycnodonte vesiculare, is described from the Santonian Chalk of Kent. The living hydroid was evidently overgrown by the P. vesiculare shell and is preserved as a bioimmuration. Eisenackiella

- thanetensis gen. et sp.nov. is characterized by a hydrorhiza whose stolons bear hydrothecae alternately to the left and right, and a hydrocaulus consisting of several unbranched stems with alternating hydrothecae. The widely spaced stolonal Hydrothecae have adnate proximal parts and erect distal parts. Assignment to an extant hydroid family is difficult: whereas the hydrorhiza resembles that of the family Lafoeidae, the hydrocaulus is reminiscent of the family Sertulariidae.</ABSTRACT>

4050 <TITLE>Temperate, meteoric diagenesis of Pliocene skeletal carbonates from eastern England.</TITLE>
4051 <SOURCE>J. geol. Soc. London 140: 377-385.</SOURCE>
4052 <ABSTRACT>The Crags of eastern England include marine skeletal carbonates which were deposited and lithified under temperate conditions. The Coralline Crag (Pliocene), in particular, exhibits a variety of carbonate cement types which indicate exposure to meteoric ground-waters during a regressive period. * The Coralline Crag has been divided into an upper division of dominantly well sorted skeletal calcarenites and calcirudites and a lower, poorly sorted silty calcarenite division. 'Dogtooth' spar cement and rudimentary syntaxial cement overgrowths on echinoderm fragments are characteristic of the sediments of the upper division, which has undergone extensive aragonite dissolution. This division is consequently relatively evenly cemented. In the underlying sediments aragonite dissolution has not occurred and the sediments have remained largely uncemented, with cement restricted to irregular patches where growth of intra- and inter-particle equant spar has effectively eliminated porosity. In contrast with the upper leached sediments, syntaxial echinoderm overgrowths show a greater development but only where interference from surrounding sediment and sparry cement was absent. The elongate shape of the Coralline Crag outcrop may be the result of preferential cementation of the upper, coarser, well sorted calcarenites originally deposited as an elongate sediment body, possibly as an offshore sandbank. 4102 <TITLE>New species and records from the Eocene of England and France
support early diversification of the coral genus Acropora.</TITLE>
4103 <SOURCE>Journal of Paleontology 82, 2: 313-328.</SOURCE>
4104 <ABSTRACT>Five new species of the highly successful reef-building coral
genus Acropora are described from Eocene locations in England and
France (Acropora britannica, A. alvarezzi, A. wilsonae, A. bartonensis,
and A. proteacea) and additional records are given for six fossil
species (A. deformis, A. anglica, A. solanderi, A. roemeri, A.
lavandulina, and A. ornata), based on re-examination of material in the
collections of the Natural History Museum, London. Specimens came from
the Lutetian (49.0 to 41.3 Ma) of France, Bartonian (41.4 to 37.0 Ma)

of England and France and Priabonian (36.0–34.2 Ma) of England. Included are the earliest record of a species with tabular or plate-like colonies similar to those in the modern *Hyacinthus* species group (*A. proteacea* n.sp.) and the earliest records of simple hispidose forms (*A. bartonensis* n.sp. and *A. roemeri*), similar to those in the modern *Hyacinthus florida* species group. The Priabonian material from southern England (*A. britannica* n.sp. and *A. anglica*) shows the earliest occurrence of two sturdy species groups, the *Hyacinthus humilis* II and *Hyacinthus robusta* groups respectively, which now occur together on reef fronts throughout the modern Indo-Pacific. The new descriptions and records contribute to evidence that the genus diversified rapidly after its appearance in the fossil record. This diversification may have contributed to the rapid speciation and dispersal, observed in this genus during the Neogene, culminating in its extraordinary dominance of modern Indo-Pacific reefs. </SOURCE>
4156 <ABSTRACT>Some Archaeocyathan cups have been found in two different
localities of the same Brusque Unit, along the Arnac-Brusque road
(Tarn). The first one is correlated with the small carbonaceous lenses
containing Epiphyton. Cyanophyceans and Archaeocyathans (Retecoscinus
boyeri Debrenne), situated in the Minervoies to the base of the mixed
carbonate/siliciclastic transitional horizon (alternances;
Upper Orbiel Formation) in the Southern flank of the Montagne Noire.
The second one (K2b Donnot and Guérangue 1978, contains highly
distorted cups (Graphoscyphia and Coscinocyathus) which are not
correlable with any formation of the Southern Flank. The generic
composition of the Archaeocyathan fauna suggests a Middle Lower
Cambrian age for the fossiliferous rocks of the Northern part of the
Montagne Noire.</ABSTRACT>

4219 <TITLE>Palaeogeographic and biostratigraphic distribution of Archaeocyatha in Spain.</TITLE>
4220 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 2]: 341-354.</SOURCE>
4221 <ABSTRACT>The biostratigraphy for the Lower Cambrian succession in Spain as proposed by Perejon (1986) is here modified on the basis of new observations. The finding of new outcrops of unquestionable Lower Cambrian age in the Spanish Pyrenees (Gerona) which bear a diverse and abundant archaeocyath assemblage (Abad 1987, 1989), the recently revised archaeocyath systematics, palaeogeography and biostratigraphy and new data on Spanish palaeontology suggest a revision of the biostratigraphic framework. This also allows new observations to be made upon archaeocyath systematics, biostratigraphy and palaeogeography. The Lower Ovetian Substage includes Capsulocyathus and another 22 genera in Zone I; Robertocyathus, Tumulocyathus, Sclerocyathus, Gordonifungia, Tumulifungia, Geocyathus, Spinosocyathus and another 25 genera appear in Zone II; Echinocyathus and 21 further genera appear in Zone III. The Upper Ovetian Substage includes three archaeocyath genera in Zone IV; five genera of wide stratigraphic range appear in Zone V; Dictyofavus and another seven genera are presented in Zone VI; and Anthomorpha, Porocoscinus, Prismocyathus and 19 further genera appear in Zone VII. The Lower Marianian Substage includes eight archaeocyath genera in Zone VIII; Mennericyathus, Densocyathus, Chouberticyathus and another 18 genera occur in Zone IX.</ABSTRACT>

4414 <TITLE>Archaeocyatha from the Wojcieszow Limestone. [in Polish, with English summary]</TITLE>
4415 <SOURCE>Przeglad Geologiczny 55, 12, 2: 1112-1116. <http://www.pgi.gov.pl/></SOURCE>
4416 <ABSTRACT>This is an introductory presentation of Archaeocyaths found near Myslow in the Kaczawskie Mountains [Sudetes]. Estimating the exact age of the Archaeocyaths-containing Wojcieszów Limestone, has been a matter of dispute. Previously regarded as Cambrian, they were recognised as Silurian in 2000 (Skowronek & Steffahn). After more than 120 years of controversies this finding finally proves Early Cambrian age of this unit. Introductory taxonomic studies have shown similarity between Myslow Archaeocyaths - represented, among others, by genera Dokidocyathella, Erismacoscinus, Afiacyathus, Leptosocyathus and Protopharetra - and those from the Doberlug syncline (Germany). This dating is of great importance for establishing the lithostratigraphic column of the Kaczawa Mountains and Cambrian palaeogeographic reconstructions.</ABSTRACT>

4427 <TITLE>Lower Cambrian reef mounds of Sierra Morena (SW Spain).</TITLE>
4428 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 185-192.</SOURCE>
4429 <ABSTRACT>The microbial-archaeocyathan reef mounds of Sierra Morena have different characteristics, related to the position in the carbonate platform, the spatial distribution of facies and the internal structure. The organic components are algal structures mainly, with cryptalgal and calcimicrobes boundstones; the archaeocyathans are accessory elements. The mixed platform in the Sierra de Cordoba presents reef mounds built by archaeocyathan framework in the Arroyo Pedroche section. A reef complex was developed in the Las Ermitas hill, where the bioherms are constituted by calcimicrobes and scattered archaeocyathans. The Alconera reef mounds are formed by cryptalgal structures, such as thrombolites, stromatolites and stromatolites, associated to scarce archaeocyathans. Other types of bioherms are constituted by calcimicrobes, stromatolites and archaeocyathans. These reef mounds are overlapping and Cambrian karstic structures have been recognized.</ABSTRACT>

4583 <TITLE>The Upper Ordovician coral fauna of Belgium and its palaeobiogeographical significance.</TITLE>
4584 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 259-270.</SOURCE>
4585 <ABSTRACT>Carbonate facies are not common in the Lower Paleozoic sections of Belgium. Limestones and calcareous shales are only present in the Upper Ordovician Fosses Formation in the Sambre-et-Meuse area, between the Brabant Massif and the Ardenne. In these levels, dated as Ashgillian, numerous green algae, as well as rugose and tabulate corals have been found. Their presence was probably related to a general warming event in the Ashgillian. However, it also indicates possible palaeotropical conditions for the area of sedimentation, implying that the Sambre-et-Meuse area was probably located in low latitudes during latest Ordovician time. This is further evidence for the rapid drifting of the East Avalonia terrane from Gondwana towards Baltica.</ABSTRACT>

4596 <TITLE>Novoe o tabulatakh i geliolitoideakh Ordovika zapadnogo sklona Urala. [new data on Ordovician Tabulata and Heliolitida of western slopes of Urals; in Russian]</TITLE>
4597 <SOURCE>Trudy Inst. geol. geokhim. AN SSSR, Ural. nauch. centr. 128 [G.N. Papulov & M.G. Breyvel (eds): Novye materialy po paleontologii Urala]: 31-48.</SOURCE>
4598 <ABSTRACT>This is a report on the stratigraphical range of Tabulata and Heliolitoidea from the late Middle and Upper Ordovician at the western slopes of central Urals, which is based on new identifications. Species previously described as from the Ordovician are in fact Silurian in age. The invalidation of the genus Praesyngopora Ivanov has been confirmed: it is a younger synonym of Uralopora Sokolov 1951. * Two species of the Tabulata are described: Uralopora flexibilis Sokolov 1931 and - as a new species - Lyopora crassiana, as well as three species of the Heliolitoidea: Cyrtophyllum bellum Ivanov 1930, and - again as a new species - Acdalopora ivanovi and Plasmoporella angusta.</ABSTRACT>

4609 <TITLE>Ordovician Reefs of the Ural Mountains, Russia: A Review.</TITLE>
4610 <SOURCE>Facies 35, 1: 1-7.</SOURCE>
4611 <ABSTRACT>The Upper Ordovician reefs of the Urals were formed at a subsiding shelf-margin during an early Late Ashgillian (Surya time interval) regressive phase. Reefs of this age were studied in detail

- from the western slope of the Northern, the Subpolar and the Polar Urals with respect to lithofacies, biotic composition and paleogeographical patterns. The thickness of the reefs varies between 100 and 500m. The backreef areas are characterized by lagoons with increased salinity and sabkha development. Microbial associations and a diverse algal flora (Cyanophyta, green and red algae and alga incertae sedis) are the main constituents of reefal boundstones. Tabulate and rugose corals, heliolitids, calcareous sponge-like fossils, bryozoans and problematic hydroids were also part of the reef communities. Each reef exhibits a characteristic framework-building association. Reef development was terminated by a rapid and abrupt sea-level rise at the end of the middle Upper Ashgillian connected with the global Late Ordovician glaciation.</ABSTRACT>

4622 <TITLE>A preliminary study of Ashgill carbonate beds from the lower part of the Fosses Formation (Condroz, Belgium).</TITLE>
4623 <SOURCE>Geological Magazine 130, 5: 673-679.</SOURCE>
4624 <ABSTRACT>The sedimentology and palaeontology of carbonate beds in the lower part of the Fosses Formation (Ashgill of the Condroz area, central Belgium) have been investigated. Two depositional interpretations are suggested: deposition either near a platform-ramp margin as bioclastic turbidites and interbedded shales or on a shelf as a transgressive sequence following a regressive event. Faunal affinities with the Baltic area and Wales are confirmed, and the location of Belgium in the tropics during the Ashgill is supported by the calcareous algae and the coral fauna. [note: tabulate and rugose corals are illustrated for the first time from the Belgian Ordovician; systematic works are still in progress on these groups, particularly the Halysitids, studied with B. Hubmann; new outcrops in the Upper Ordovician of the Condroz area are investigated by the same team]

4753 <SOURCE>Trudy Inst. geol. geokhim. AN SSSR, Ural. nauch. centr. 129 [V.P. Sapelnikov & B.I. Chuvashov (eds): Paleontologiya nizhnego Paleozoya Urala]: 20-38.</SOURCE>
4754 <ABSTRACT>Two new species of Tabulata are described: Issolites fallax n.gen. et n.sp. and Catenipora festina n.sp. as well as nine new species of Heliolitida (Propora uralica, Diploepora bona, Helioplasmolites parvus, H. interruptus, H. lacer, H. bonus, H. (?) ramosus, Heliolites absonus, H. insolens). All of them are from the Llandovery, Wenlock and Ludlow and regarded to be an endemic fauna. * The new genus Issolites from the Ludlow is assigned to the family Favositidae Dana, 1846. * Diagnosis: Corallum mainly lump-shape. Corallites distinctly differentiated in size: large, polygonal corallites are separated from each other by 1-2 rows of smaller 4-6 edged corallites. Corallite walls relatively thick. Pores round, transformed into canals in the thick walls. Base normal, usually horizontal. Thorns present. Type species and holotype: Issolites fallax Yanet 1977: p. 21, pl. 1 1-2; pl. 2: 1; from the Issovskian horizon, Ludlow, eastern slopes of the Urals. Comments: The dimorphism of the corallites being an essential difference against Favosites is emphasized. Issolites halisitoides (Northrop 1969) from the Wenlock(?) of Canada is presented being a questionable synonym of Issolites.</ABSTRACT>

(Spain and Portugal).</TITLE>
- 4766 <SOURCE>Journal of Paleontology 71, 4: 554-563.</SOURCE>
- 4767 <ABSTRACT>The first-described articulated Silurian sponges from Spain
and Portugal include a moderate assemblage of hexactinellids and a
single monaxonid demosponge. The sponges were collected from a thin
layer at the top of the Cyrtograptus lundgreni-Monograptus testis
graptolite biozone, in a possible volcanic ash of latest Homeric
(Wenlock) age. The sponges are from southeastern Portugal and
southwestern Spain in the Ossa-Morena Zone of the Hesperian Massif. The
hexactinellid collection includes several specimens of the new species,
Protospongia iberica, and fragments of Diagoniella species and Gabelia
(?) sp. Specimens of the latter two taxa are too small for species
identification. Demosponges are represented by a single described
specimen of a probably new genus and species preserved as a "wreath
" of monaxon spicules. Dermal and gastral layers are of very fine
spicules developed over the moderately coarse, aligned, principal body
spicules.</ABSTRACT>

4804 <TITLE>Spongophyllidae (Rugosa) of Bohemian Silurian and Devonian.
</TITLE>
4805 <SOURCE>Sbornik narod. Mus. Praha 39, 2: 115-126.</SOURCE>
4806 <ABSTRACT>The family Spongophyllidae from the Silurian and Devonian of Bohemian Massif is reviewed. Two genera with three species, one of them new, are described: Carlinastraea kettneri (Prantl 1951), Carlinastraea martinae sp.nov., and Kozlowiaphyllum inficetum (Pocta 1902). Their relations to European and some North American and Asian faunas are discussed. [original abstract]</ABSTRACT>

4819 <ABSTRACT>All stromatoporoid species described by Pocta (1894) from the Silurian and Devonian of Bohemia have been revised. Very extensive new collections of stromatoporoids are coming from quarries near the Bohemian village Koneprusy (ca. 30 km southwesterly of Prague). These stromatoporoids have been collected in the Koneprusy Limestone of Pragian age and the Acanthopyge Limestone of Eifelian to Lower Givetian age. The Koneprusy Limestone contains a large reef complex. Most of the Koneprusy Limestone succession including all stromatoporoids and the reef complex belong to the kindlei conodont zone (middle Pragian). The stromatoporoids and the other reef-building organisms show a clear dependence on the facies (resp. position within the reef complex). The stromatoporoid fauna of the Koneprusy Limestone contains 15 species, but only 7 of them have been described by Pocta (1894). The new species Stromatoporella anamariae n.sp. is described. The Pragian of the Barrandian was no refuge for the stromatoporoids of the Eastern Americas Realm. Biogeographically, all stromatoporoid faunas of Bohemia belong to the Old World Realm. Nevertheless, the stromatoporoid fauna of the Acanthopyge Limestone is much more cosmopolitan than the fauna of the Koneprusy Limestone. The stromatoporoid fauna of the Acanthopyge Limestone is composed of 19 species, all of which are known from other occurrences in Europe, Asia, or Australia - except of Actinostroma vastum Pocta, 1894 and Stromatoporella pertabulata preisleriensis n. ssp. The stromatoporoids of the Koneprusy Limestone frequently contain commensalic worm-like organisms and only rarely the new auloporoid tabulate coral Syringopora praehanshanensis n.sp. In the Acanthopyge Limestone the new species Syringopora hladili n.sp. and three other Syringopora species occur. Possible reasons for the scarcity of stromatoporoids and reefs in the Lower Devonian may be the water temperature, the lack of branching and encrusting stromatoporoids, and the scarcity of commensalic Syringopora corals.

4832 <ABSTRACT>Two species - one of them with 2 subspecies - come from Silurian strata, the other 9 valid species (and 2 synonyms) come from Lower Devonian strata. For every species, the recent name, the synonyms, the type material, the exact type locality, and a diagnosis is given. Lectotypes are designated for 6 species. The new species Schistodictyon koneprusiense - from the Middle Pragian of Koneprusy (central Bohemia) is described.</ABSTRACT>

4871 <ABSTRACT>At the road-side near Lothmecke a coral reef is exposed on top of a fossil-bearing siltstone. The fauna of the siltstone and the coral reef - as well as its composition - are described. From this conclusions are drawn regarding the environment at the time of sedimentation. The chronological dating is discussed. The reef belongs to the Ihmerter beds, part of the lower Honseler strata (of the lower Givetian). The "normal" silty bottom fauna of the Ihmerter beds

- is compared with the reef fauna. References are also given. </ABSTRACT>

- 4897 <ABSTRACT>New recoveries of Trilobita, Anthozoa and Conodonta from the linguiformis Zone close to the Frasnian/Famennian boundary and immediately preceding the Upper Kellwasser Event level at Schleiz (Thuringia) are investigated. The trilobites species are Harpes neogracilis Richter & Richter, 1924, Palpebralia cf. brecciae (Richter, 1913) and Acuticryphops acuticeps (Kayser, 1889), the latter is represented by several morphs with different numbers of eye-lenses; the trend to eye-reduction is discussed. The Rugosa fauna that was nearly unknown from the psychrospheric facies worldwide, comprise six taxa of the Cyathaxoniina. The rich conodont faunas permit tracing the exact boundary between the top of the Late Palmatolepis rhenana Zone and the Palmatolepis linguiformis Zone.</ABSTRACT>

- 4909 <SOURCE>Acta Palaeontologica Polonica 50, 2: 315-328. <http://www.app.pan.pl/article/item/app50-315.html> </SOURCE>
- 4910 <ABSTRACT>Most of 378 upper Eifelian crinoid columnals collected from the lower part of Skały Beds in the Holy Cross Mountains display traces of borings produced by endobionts, but only approximately 20% of them show traces of epibionts. These infested crinoids are represented by 5 stem-based species: Tantalocrinus scutellus Le Menn, 1985,

Schyschcatocrinus creber Dubatolova, 1975, Gilbertsocrinus vetulus Moore and Jeffords, 1968, Pentagonostipes petaloides Moore and Jeffords, 1968, and Cycloocetocrinus sp. They were fouled by 19 species of suspension-feeding epibionts, including saccamminid foraminiferans, rugose and tabulate corals, cyrtinitid and productid brachiopods, ctenostome bryozoans, cyclostome bryozoans, cystoporate bryozoans and rhabdomesid? bryozoans, crinoids, and organisms of uncertain affinities. The majority of these epibionts were opportunistic commensals colonizing living crinoids, and only some utilized dead crinoids as hard substrate for attachment. At least some of these epibionts seem to have settled selectively on particular crinoid host species.

4923 <ABSTRACT>Fossiliferous localities in the Middle Devonian strata of the Attendorn-Olpe Area (western Sauerland) and their fossil contents are listed. Selected fossils are figured. This increases the knowledge of the Middle Devonian fauna of the south-western Sauerland significantly. Especially remarkable are the following fossils: the asterozoan Eospondylus sp. from the upper part of the Selscheid Beds (Upper Eifelian), the tabulate coral Aulopora (Aulopora) ex gr. liber Scrutton 1990 from the Upper Newberria-Beds (Lower Givetian), the rugose coral Cyathopaedium paucitabulatum (Schlüter 1880) from the Upper Newberria-Beds (Lower Givetian), the stromatoporoid Talestroma pachytextum (Lecompte 1952) from the Massenkalk limestone (Upper Givetian?), the tabulate coral Thamnopora bilamellosa Ermakova 1960 from the Massenkalk limestone (Upper Givetian?), and the rugose coral Smithiphyllum belanskii Pedder 1965 from the Massenkalk limestone (Upper Givetian?). Thamnopora schouppiei Brühl 1999 is a junior synonym of Coenites vermicularis (McCoy 1850). The whole material has been collected by Mr. Ludwig Korte. It is stored in the Kreisheimatmuseum Attendorn.</ABSTRACT>

4961 <SOURCE>Trab. Geol. Univ. Oviedo 16: 25-35 [in Spanish, with English summary].</SOURCE>
4962 <ABSTRACT>The Devonian formations of the Asturoleones region in the Cantabrian mountains, entirely marine, are characterized from a paleontological point of view by their rich faunal content, specially in benthonic organisms. An important part of these faunas consists of corals (Rugose and Tabulates) and Stromatoporoids. In detrital formations Furada-San Pedro, Naranco-Huergas and Pineres-Nocedo, Fueyo, Ermita) corals are scarce due to unfavourable environmental conditions and the associations, if present, are almost exclusively referred to "Cyathaxonia-Fauna", whose stratigraphical value is relative and only local. However, calcareous formations (Raneces-La Vid, in part, Moniello-Santa Lucia and Candas-Portilla) show reef episodes with a great abundance of coral fauna, where the numerous associations have a notable stratigraphical value as also, in many cases, paleobiogeographical, not only on a merely local but also on a worldwide scale.</ABSTRACT>

4999 <TITLE>Fauna from the limestones at the Frasnian / Famennian boundary at Mokra (Devonian, Moravia, Czechoslovakia).</TITLE>
5000 <SOURCE>Sbor. geol. Ved, Paleont. 30: 61-84.</SOURCE>
5001 <ABSTRACT>The reef-building fauna of the Mokra section, extincted in the upper part of the conodont *Palmatolepis crepida* Zone. Into the lower Famennian, penetrated namely less diversified euryfacies species. The decrease in the diversity is being associated with the Kellwasser eustatic and climatic events proved today, from a general viewpoint, from the mid-levels of the *Palmatolepis gigas* Zone up to its top (Walliser 1985, 1986) and supposed up to the mid-levels of the *Palmatolepis triangularis* Zone (the so-called Crickites Event - Kalvoda 1986). In the Section, the Frasnian / Famennian boundary is restricted to the gap between the intervals I and II. Under the gap, occur *Scoliopora kaisini* (Lecompte) and the foraminifers *Nanicella* sp.- species so far found in Moravia exclusively up to the upper limit of the conodont *Palmatolepis gigas* Zone, while above the gap lower Famennian *Labechia cumularis* Yavorskiy and *Syringopora volkensis* Tschernyshev appear already. The gap very likely involves the current critical interval of the Frasnian / Famennian boundary corresponding to the lower third of the *Palmatolepis triangularis* Zone. By contrast, the prominent lithologic change between the Macocha and Lisen Formations (above int. IV) and extinction of sessile benthos (by 3 to 5 cm lower in the section) do not lack a biostratigraphic record - both the underlying and overlying levels provide autochthonous conodonts of the upper part of the *Palmatolepis crepida* Zone.</ABSTRACT>

5012 <TITLE>Corals and other reef building organisms of the higher Eifelian and lower Givetian (Devonian) from the northwestern Sauerland (Rhenish Schiefergebirge).</TITLE>
5013 <SOURCE>Muenster University, Unpublished thesis: 452 pp., 51 figs., 49 pls [in German with English summary].</SOURCE>
5014 <ABSTRACT>The Ihmert Formation is subdivided into Bergfeld-Member (lower Upper Eifelian). Gruenewiese-Member (uppermost Eifelian). and Dannenhoefer-Member (lowermost Givetian). The material has been collected mostly in the coral limestones of the Gruenewiese-Member and the Bredenbruch-Member (lower Lower Givetian) of the Unterhonsel-Formation. From the Middle Eifelian to middle Lower

- Givetian of the northwestern Sauerland (Eastern Rhenish Schiefergebirge) 30 different tabulate corals and 21 different rugose corals are described, as well as 21 species of stromatoporoids, 16 of calcareous algae, and 2 of chaetetids. Only the tabulate coral *Squameoalveolites strigosus cusanorum* n.ssp., the rugose coral *Smithiphyllum kloeckneri* n.sp., and an unnamed calcareous red alga are new. 5 tabulate corals, 3 rugose corals, 3 stromatoporoids, and 1 calcareous alga are described for the first time from Central and Western Europe, but this fauna is in good accordance with the reef-builder fauna of the Eifel Hills and Ardennes. Many species show an important expansion of their known stratigraphical range. The most Devonian reef-builders allow only rough stratigraphical classifications. [first fragment of extensive summary] </ABSTRACT>

 5038 <TITLE>Die ehemalige Givet-Fossilfundstelle Buechenberg im Unterharz.</TITLE>
 5039 <SOURCE>Hall. Jb. Geowiss. 15: 21-42. [in German, with English summary]</SOURCE>
 5040 <ABSTRACT>Buechenberg fossils (Rugosa, Trilobita), described by Roemer (1843 - 1855) come from locally developed Greifenstein facies within the off-reef realm of the Stringocephalus Limestone. Outcrops on the north flank of Buechenberg anticline (north of Elbingerode) had arisen and vanished in connection with iron ore mining, and most fossils always had been collected from loose debris material only. Conodonts indicate the varcus zone (probably middle varcus at all) in accordance with old ammonoid records (Koch 1896, Maenioceras terebratum zone) from nearby pelagic cephalopod limestones. The trilobite fauna corresponds to the facially identical Acanthopyge-Phaetonellus community of Bohemian Lower Eifelian. Concomittantly occurs a tentaculitic association of postotomari-bianulifera zones. Anthozoa bearing beds are differentiated into Amplexus-limestone and Bainbridgia-limestone. (Original summary) * The chapter Anthozoa contains figures of Amplexus? hercynicus Roemer 1855, Laccophyllum sp., Cyathaxonia? hercynica Roemer 1855, and Bainbridgia alternans (Roemer 1850).</ABSTRACT>

5051 <TITLE>Ein Korallen-Horizont im Unteren Banderschiefer (hoechstes Mittel-Devon) von Hohenlimburg-Elsey im Nordsauerland (Rheinisches Schiefergebirge).</TITLE>
5052 <SOURCE>Berliner geowissenschaftliche Abhandlungen E18: 209-241.</SOURCE>
5053 <ABSTRACT>Basinal shales of the Lower Banderschiefer Formation (Upper Givetian, Pharciceras Stufe) yielded for the first time in Hohenlimburg-Elsey (City of Hagen, northern Rhenish Massiv) an allochthonous shallow-water fauna dominated by corals. Among a total of twenty-four taxa the solitary Rugosa Acanthophyllum concavum simplex and Macgeea multizonata as well as the branching tabulates Alveolites (Alveolitella) polenowi and Scoliopora denticulata are abundant. Other Rugosa, Tabulata, stromatoporoids, brachiopods, crinoid ossicles and nautiloids occur as minor faunal elements. M. multizonata, A. (Alv.) polenowi and "Chaetetetes" barrandei are recorded for the first time from Germany. The unusual local lack of coarse crinoidal reef debris suggests as source a subtidal coral garden which grew marginally on top of the drowned Steltenberg Reef from where individual specimens were washed downslope during storm events. The fauna combines Upper Givetian and Lower Frasnian species and contributes to the understanding of coral biostratigraphy at the Middle / Upper Devonian transition.</ABSTRACT>

5065 <SOURCE>Facies 26: 103-116.</SOURCE>
5066 <ABSTRACT>The prevailing sandy / silty lower part of the Middle Devonian in the northwestern Sauerland includes two coral limestone horizons, which contain a rich fauna of corals, stromatoporoids, and calcareous algae. The Ihmert-Formation is subdivided into three parts. The older coral limestone horizon is the Gruenewiese-Member of the Ihmert-Formation (uppermost Eifelian), the younger is in the Bredenbruch-Member of the Unterhonsel-Formation (lower Lower Givetian). Conclusions about the environmental constraints are drawn from the sedimentology and the fossil content of the coral limestones. Predominant biostromes are built between storm wave base and normal wave base. Only the few bioherms grew above the normal wave base. These coral limestones were deposited in a tropical or subtropical normal marine environment in the shallow euphotic zone. Among the reef-builders epocism is very frequent, and until now this phenomenon has not been investigated in detail. Fragile rugose and tabulate corals lived as commensals with stromatoporoids. Some other aspects of paleoecology are concisely presented.</ABSTRACT>

5077 <TITLE>Paleoecology and paleobiogeography of corals and other reef-builders from the Middle Devonian of the Sauerland (Germany).</TITLE>
5078 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 2]: 147-159.</SOURCE>
5079 <ABSTRACT>In the NW Sauerland the coral limestone horizons of the uppermost Eifelian and the Lower Givetian show a very rich content of fossils: 28 tabulate coral species, 21 rugose coral species, 21 stromatoporoid species, 2 chaetetid species, and 16 calcareous algae species were identified by the author. They generally lived in a warm, normal marine environment in the shallow euphotic zone. An analysis of the lagoonal Massenkalk sediments (upper Lower Givetian to Frasnian) shows intertidal to subtidal cyclic sedimentation. Herein several reef-builder associations can be recognized. Their composition and distribution depend on water depth as well as on the restriction of their environment. The Upper Eifelian and Lower Givetian reef-builder fauna of the Sauerland corresponds to the fauna of the Eifel Hills and the Ardennes, but a few of the Sauerland species are up to now only known from occurrences east of it. The Rhenohercynian Basin was a marginal sea, into which faunas from the Asiatic part of the Old World Realm immigrated. A marine connection to the Eastern Americas Realm was opened in the Upper Givetian.</ABSTRACT>

- 5156 <SOURCE>FC&P 18, 2: 6-10.</SOURCE>
- 5157 <ABSTRACT>For more than 200 years the Middle Devonian limestone synclines of the Eifel have been famous for their great variety of fossils. These limestone synclines swim like a ship's formation in a beam line in the "water" of the enormous sandstone-series and shales of the Rhenish Lower Devonian. The two "flankships" the Sötenich syncline in the north and the Prüm syncline in the south, are the largest of all synclines, and - at the same time - the "cornerstones" in the investigation of Middle Devonian of the Eifel. Their thick deposits are interspersed with biostromes and bioherms, which even reach up as far as the Upper Devonian in the Prüm syncline. [introductory part of a note]</ABSTRACT>

- 5168 <TITLE>Toward an exact age of Middle Devonian Celechovice corals - Past problems in biostratigraphy and present solutions complemented by new magnetosusceptibility measurements.</TITLE>
- 5169 <SOURCE>Coral Research Bulletin 7: 065-071. [Dieter Weyer's 65th birthday commemorative volume; S. Schröder, H. Löser & K. Oekentorp (eds)]</SOURCE>
- 5170 <ABSTRACT>First discovery of the rich coral faunas of the Celechovice (Moravia) section was in the 1830s. This Celechovice section belonged to the classical outcrops which were visited by prominent geologists who first described the Devonian system. However, a mistaken identification of the brachiopod, "Stringocephalus burtini", in a position below the coral horizon with Calceola sandalina presented a long-term biostratigraphic problem. Because of this identification, many paleontological papers pushed the age of this coral horizon to the Late Givetian. An opposite trend (i.e., to keep the age of the coral horizon close to the Eifelian/Givetian boundary) began with regional correlation of trilobites (Schizoproetus) in 1960s. This continued with revisions of thick-shelled brachiopods ("Stringocephalus" = Kaplex obesissimus Ficner & Havlíček 1975) in the 1970s, and it culminated in 1990s, with numerous studies on trilobites, corals, conodonts, dacryoconarids and crinoids. In spite of these modern biostratigraphic data, the exact age of the coral horizon remained unclear. It fluctuated within a wide range between the Eifelian/Givetian and Lower/Middle Givetian boundaries. Magnetosusceptibility stratigraphy allows the projection of the E/G GSSP (Jbel Mech Irdane, Morocco) 5m below the base of the Celechovice Upper Dark-colored Interval (abbrev. CUDI; beds 117-146), approximately 10m below the most productive, world-famous Celechovice "Fossil Korallen-Lagerstätte". According to the correlation of the magnetics with the standard conodont zones, the age of the richest Celechovice coral fauna is between the earliest Givetian hemiansatus and Early varcus zones. 5220 <TITLE>Zur Fauna und Stratigraphie der cultrijugatus-Schichten (Wende Unter- / Mittel-Devon) im West-Sauerland (Rheinisches Schiefergebirge).</TITLE>
5221 <SOURCE>Coral Research Bulletin 05: 103-119.</SOURCE>
5222 <ABSTRACT>within the southwestern part of the Ebbe Anticline (Western

Sauerland, Rhenish Massif) the cultrijugatus Beds represent the upper Upper Emsian and Lower Eifelian. Based on lithological differences of the vertical sequence it is possible to subdivide these beds into the Lower, Middle and Upper cultrijugatus Beds in the area of Kierspe and Meinerzhagen. The Lower / Middle Devonian boundary is in the Middle cultrijugatus Beds. The previous [Meinerzhagener Korallenkalk](#); named Upper cultrijugatus Beds include reefoid structures (biostromes) and contain a rich fauna of reef-builders. The stromatoporoids *Schistodictyon amygdaloides subvesiculosum* (Lecompte 1951) and *Clathrocoilon (Clathrocoilon) curiosa* (Bargatzky 1881), the chaetetid *Pachythea stellimicans* Schlueter 1885, the tabulate corals *Thamnopora angusta* Lecompte 1939, *Alveolites (Alveolites) edwardsi edwardsi* Lecompte 1939, *Alveolites (Alveolites) intermedius* Smith 1933, *Squameoalveolites fornicatus* (Schlueter 1889), *Coenites vermicularis* (McCoy 1850), and *Platyaxum (Roseoporella) gradatum* (Lecompte 1939) as well as the rugose corals *Cyathophyllum (Peripaedium) planum* (Ludwig 1866), *Acanthophyllum heterophyllum* (Milne-Edwards [1851](#)), and *Mesophyllum (Mesophyllum) cylindricum* (Schlueter 1882) are described from the Upper cultrijugatus Beds south of Kierspe, respectively west of Meinerzhagen. *Schistodictyon amygdaloides subvesiculosum*, *Alveolites (Alveolites) intermedius*, and *Coenites vermicularis* are found in the Eastern Rhenish Massif for the first time. The coral limestones originated in a period of reduced sediment supply within a tropical or subtropical, shallow marine environment. The stratigraphical ranges of the investigated reef-builders demonstrate, that the reef-builder fauna was not affected perceptibly by the jugleri Event (= Chotec Event) of the Lower Eifelian. Instead of this, the reef-builder fauna shows a remarkable continuity within the whole Eifelian.

5234 <SOURCE>Geol. Palaeont. Westf. 24: 5-93. [in German, with English summary]</SOURCE>

5235 <ABSTRACT>The prevailing sandy-silty lower part of the Middle Devonian in the northwestern Sauerland includes two coral limestone horizons, which contain a rich stromatoporoid fauna besides many corals (Tabulata and Rugosa) and calcareous algae. Bryozoans are unimportant reef-builders. The entire fossil content is listed up and concisely discussed. At first the lithostratigraphical subdivision, the biostratigraphical classification, and the facies of the sequence are discussed. The Ihmert-Formation is subdivided into Bergfeld-Member (lower Upper Eifelian), Gruenewiese-Member (uppermost Eifelian), and Dannenhoefer-Member (lowermost Givetian). 21 stromatoporoid species are described from the coral limestone horizon of the Gruenewiese-Member and the Bredenbruch-Member (lower Lower Givetian) of the Unterhonsel-Formation. The classification of stromatoporoids by Stearn (1980) is applied with minor modifications. *Dendrostroma fibrosum* Galloway 1960, *Trupetostroma dushanense* Yang [1963](#) and *Stachyodes (Stachyodes) dendroidea kuznetskensis* (Yavorsky 1957) have been found in Europe for the first time. 8 other stromatoporoids are described from the Rhenish Massif for the first time as well. Lectotypes are designated for *Actinostroma dehornae densicolumnatum*

Lecompte 1951, *Stromatoporella solitaria* Nicholson 1892 and *Stachyodes* (*Stachyodes*) *dendroidea kuznetskensis* (Yavorsky 1957). *Synthetostroma* Lecompte 1951 is considered as a subgenus of *Clathrocoilona* Yavorsky 1931. *Clathrocoilona spissa* (Lecompte 1951) is so similar to *Clathrocoilona solidula* (Hall & Whitfield 1873) from the Upper Devonian of the U.S.A., that it is valued as a subspecies of *solidula*. Probably the stromatoporoid skeleton consisted originally of high-magnesian calcite, now less diagenetically altered than aragonite, but more than calcite. Remarks to the biogeography of Devonian stromatoporoids are given in this paper. Conclusions about the environmental constraints are drawn from the sedimentology and the fossil content of the coral limestones. The predominant biostromes are built between the storm wave base and the normal wave base. Only the few bioherms grew above the normal wave base. These coral limestones are deposited in a tropical or subtropical normal marine environment in the shallow euphotic zone. Among the reef-builders epocism is very frequent, and till now this phenomenon has not been investigated in such an extensive Devonian material. Some other aspects of palaeoecology are concisely presented.

5272 <TITLE>Ostracodes swallowed by Palaeozoic corals? </TITLE>
5273 <SOURCE>Lethaia 26: 313-317.</SOURCE>
5274 <ABSTRACT>Middle Devonian heliolitids and favositids from Central Bohemia, belonging to *Heliolites intermedius*; *LeMaitre* and *Favosites goldfussi* Orbigny, incorporated ostracode shells within their living corallite structures. The ostracode shells were sealed in by skeletal tissue that was septal in origin (*Heliolites*) or they were roofed over by tabulae (*Favosites*). The foreign shell was near the axis of the polyp when trapped within the coral skeleton. Only ostracodes, not other rounded shells or sedimentary particles, were trapped in this way. Approximately one in 30 favositid corallites and one in 70 heliolitid corallites display this peculiar condition, where the ostracode shells seem to have been swallowed by the polyps. A probable scenario involves the injury of the mouth area and the trapping of the ostracodes. A high probability that the basal part of the polyp experienced a controlled penetration is the most striking part of the process.</ABSTRACT>

5300 <ABSTRACT>A limestone pebble with a fragment of a colony of *Heliolites* sp. was found in late Devonian (Famennian) conglomerates. This pebble represents older, possibly Silurian rocks. Limestones older than the late Devonian are most known in surface exposures in the region of Chwaliszów [Sudetes]. The finding of the pebble with *Heliolites* sp. has a great importance for palaeogeographic reconstructions.</ABSTRACT>

5311 <TITLE>Heliolitidae (Cnidaria, Tabulata) del Devonico de la Cordillera Cantabrica (NW de Espana). [in Spanish, with English abstract]</TITLE>
5312 <SOURCE>Trabajos de Geologia 21: 97-110; Oviedo.</SOURCE>
5313 <ABSTRACT>This paper constitutes the first work on the order Heliolitida (Cnidaria, Tabulata) from the Devonian of the Cantabrian Mountains. In this area, the presence of heliolitids is restricted to two moments, upper Emsian-lower Eifelian and Upper Givetian, when reefal conditions were established. In spite of the preliminary condition of this study, the systematic conclusions allow to compare the cantabrian heliolitids with those from different regions with Devonian reefal sediments and to deduce several biological behaviours of these corals. 5325 <SOURCE>Courier Forschungsinstitut Senckenberg 251: 123-133.</SOURCE>
5326 <ABSTRACT>The heterocoral Oligophylloides pachytheucus is described from the Refrath 1 Borehole. The borehole is 53m deep and consists of dark grey, in part marly mudstones with few thin intercalations of calcareous siltstones. The sediments are dated as Middle expansa Zone (late Famennian) by conodonts. The heterocorals are well preserved and multiple branched. The shape of the heterocorals suggests a procumbent living condition.</ABSTRACT>

5338 <SOURCE>Palaeontology 44, 6: 1189-1226.</SOURCE>
5339 <ABSTRACT>Studies on the taxonomy and morphology of the Famennian heterocoral Oligophylloides have placed great emphasis on the character of the soft tissue, coloniality and distal development of the skeleton with regard to the construction of the wall. Here, the existence of soft tissue covering the entire skeleton of the colony is proposed. Thirty-eight branching specimens have been found in addition to the predominant single fragments of corallites; these should be regarded as colonial with a well-developed branching form. It is here proposed that the external wall grew not only at the distal end, and that its thickening did not result from the overlapping of tabulae, but was built independently of tabulae by the soft tissue covering the whole skeleton of the colony. The following new characteristics of Oligophylloides are described: a change in the position of septa, so-called 'septal shifting'; a rearrangement of the septal apparatus; the occurrence of aulos-like structures; a groove

- ornamentation on the external wall; and the granular microstructure of the axial part of septa. A detailed study of Late Devonian Oligophylloides corals shows that *O. tenuicinctus* Rozkowska and *O. pachytheucus pentagonus* Rozkowska are synonymous with *O. pachytheucus* Rozkowska. </TITLE>
5403 <SOURCE>Acta Palaeontologica Polonica 25, 3-4: 513-517.</SOURCE>
5404 <ABSTRACT>Coral growth in Heterocorallia is described and illustrated for the first time. It has been studied in Oligophylloides pachytheucus Rozkowska 1969 from the Upper Famennian of the Świętokrzyskie (Holy Cross) Mountains, Poland. One single offset at a time was formed laterally with respect to the parent polyp. It did not inherit any septa from the parent corallite forming its own, independent set of septa. The young polyp was for a long time connected with the parent by soft tissue being separated from its skeleton by a tabulotheca. The theca and possibly all the other skeletal elements of the species studied grew centrifugally. Evidence is presented that O. pachytheucus had a distal part of its corallite in the shape of a slender distal cone with a set of septa protruding on top of the cone. [original abstract]</ABSTRACT>

- 5442 <SOURCE>Paläontologische Zeitschrift 57: 39-68.</SOURCE>
- 5443 <ABSTRACT>Additional specimens of a "by-the-wind sailor" (vevellid hydrozoan) from the Hunsruck Slate indicate that Palaeonectris Rauff is a subjective synonym of Plectodiscus Ruedemann. Silurovelella Fisher is also judged to be a synonym of Plectodiscus. The nature of the matrix and the degree of decay and flexing of the pneumatophore disc affect preservation of these fossils. The internal chitinous gas-filled float structure of Plectodiscus discoideus is often preserved as a concentrically laminated, oval disc. After death of the organism, it was separated from the soft tissues and before burial in the sediment, it may have been transported by the wind and surface currents. Some new details are added to the anatomy of P. discoideus (Rauff), and a new reconstruction is presented. [original summary]</ABSTRACT>

- 5455 <SOURCE>Senckenbergiana lethaea 66, 3/5: 269-297.</SOURCE>
- 5456 <ABSTRACT>The present paper is introduced by a survey of the stratigraphic distribution of about 90% of the actually known species of the Conulata as well as of the range of their genera.- In the Rhenish Devonian of W.Germany, these invertebrate fossils are extremely rare. All of the 18 species recorded till now belong to the family Conulariidae. With the exception of the four conulariid species of the Lower Devonian Hunsruck Shale, these taxa are revised respectively described as new.- The Lower Devonian Conularia subparallela G. Sandberger 1847 and the Middle Devonian species Conularia gerolsteinensis Archiac & verneuil 1842 and Conularia denckmanni n.sp. belong to the subfamily Conulariinae. The Middle Devonian Paraconularia deflexicosta (G. Sandberger 1847) is placed among the Paraconulariinae. The Lower Devonian species Climacoconus imodevonicus n.sp. is attributed to the Ctenoconulariinae, with reservation also the

- genus *Holoconularia* n.g. with the type species *Holoconularia hummeli* (Kegel 1926), *Holoconularia fimbriata* (Walther 1903), and *Holoconularia kiderleni* n.sp. from the Lower Devonian and with *Holoconularia eifliensis* (Steininger 1853), *Holoconularia richteri* n.sp., *Holoconularia geesensis* n.sp., and *Holoconularia? rospensis* n.sp. from the Middle Devonian; *Holoconularia ornata* (Archiac & Verneuil 1842) is the only Upper Devonian species.

5469 <ABSTRACT>The *Conularia* species from the Lower Devonian Hunsrueckschiefer are reviewed based on new material. In addition to the four species already known from the Hunsrueck region, five further species are described as new, one also from the Hunsrueck (*Conularia hunsrueckiana*) and four from the Hunsrueckschiefer of the Eifel region (*C. mayenensis*, *C. bausbergensis*, *C. bartelsi* and *Sinusconularia blasii*). The new genus *Sinusconularia* (Suborder *Circonulariina* Bischoff 1978) is described. The species from the typical Hunsrueck region, i.e. from the slate pits at Bundenbach and Gemuenden, are assigned to the Lower Emsian substage. However, according to Meyer (1986), for the species from the Eifel region, i.e. from the slate pits at Mayen and Kehrig, a Siegenian age is adopted. The evaluation of X-ray photographs is discussed with regard to the Chordata theory held by Steul (1984).</ABSTRACT>

5624 <SOURCE>Muenstersche Forschungen zur Geologie und Palaeontologie</SOURCE>
5625 <ABSTRACT>Systematic research of rugose coral from the Givetian of the Sotenich syncline (Rheinisches Schiefergebirge, Northern Eifel) lead to the identification of the following solitary species: Cyathophyllum sp., Characterophyllum longiseptatum n.sp., Characterophyllum sp., Aristophyllum sp., Grypophyllum dencknanni., Grypophyllum wedekindi, Acanthophyllum heterophyllum, Acanthophyllum. vermiculare, Acanthophyllum concavum, Acanthophyllum cf. ultimum, Stringophyllum acanthicum, Stringophyllum buchelense, Mesophyllum (Mesophyllum) vesiculosum, Mesophyllum (Cystiphyllodes) macrocystis macrocystis. Mesophyllum (Cystiphyllodes) secundum secundum, Masophyllum (Cystiphyllodes) secundum pseudoseptatum and Mesophyllum (Cystiphyllodes) secundum conistructum. The largest in number is the family of the Cystiphyllidae followed by the Ptenophyllidae. Distribution of Rugosa within the Givetian is rather uniform. Only few species, as far as envisaged, are

- restricted to particular beds making further investigations necessary concerning their stratigraphic position.

- 5651 <ABSTRACT>From cephalopod limestones dated as upper Cheiloceras-Stufe (lower marginifera zone) and quarried near Rodersdorf north-northeast of Schleiz (northwestern border of Berga anticline), the new species Neaxon cheilos is described, with discussions on stratigraphic distribution of the genus Neaxon Kullmann 1965, and on taxonomy of the subfamily Neaxoninae Hill 1981. The third order septa regularly distributed between all major and minor septa in high calicular regions of Neaxon regulus (R. Richter 1948) and Ufimia tricyclica (Schindewolf 1942) seem similar to hyposepta, but differ in their primary absence just as the most distal calicular margin. The new morphological term meiosepta is proposed for these structures appearing in a short distance below the upper calicular rim, functioning as active septa in a small zone of the highest calice, and disappearing by secondary incorporation into the thickening archaeothecal wall not far from the distal margin.</ABSTRACT>

5689 <SOURCE>Palaeontographica Americana 54: 459-464 [Oliver w.A. Jr et al. (eds): Recent advances in the paleobiology and geology of the Cnidaria: Proceedings of the 4th International Symposium on Fossil Cnidaria].</SOURCE>
5690 <ABSTRACT>Most rugose corals from the Devonian of the Cantabrian Mountains (NW Spain) can be dated in terms of conodont zones. * At present the base of the Polygnathus costatus partitus Zone is accepted as being the Lower-Middle Devonian boundary. In the Asturo-Leonese region of the Cantabrian Mountains the equivalent to that boundary could be the base of the Icriodus retrodepressus Zone. The rugose corals of the Moniello and Santa Lucia Formations will be analyzed in relation to this stratigraphic position. Recently, the Middle-Upper Devonian boundary has been interpreted as being the base of the Lower Polygnathus asymmetricus Zone, equivalent to the transition Ancyrodella binodosa-Ancyrodella rotundiloba. The association of rugose corals from the Candas and Portilla Formations are listed with respect to this transition which is well established in the Cantabrian Mountains. 5728 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Sciences de la Terre 74: 19-34.</SOURCE>
5729 <ABSTRACT>Temnophyllum delmeri n.sp., and T. ramosum n.sp. are described in detail and come from the Upper Givetian of Belgium. On the south side of the Dinant Synclinorium, T. delmeri is associated with Sunophyllum beichuanense He, 1978 and Wapitiphyllum laxum (Gürich, 1896), at the top of the Mont d'Hairs Formation. It is also present in the Flohimont Member, the lower subdivision of the Fromelennes Formation. At the base of the overlaying Moulin Boreux Member, there is a level of limestones rich in stringocephalids, diverse groups of tabulate corals and in rugose corals represented by W. laxum, Temnophyllum ramosum, T. delmeri and locally Sunophyllum beichuanense. Nearly all these fossils disappear higher in the Moulin Boreux member. The same situation has been observed in the Philippeville Massif, on the north side of the Dinant Synclinorium and in the Vesdre Massif. As the base of the Flohimont Member lies at the top of the Lower Polygnathus varcus Zone and as the major part of this lithographic unit belongs to the P. ansatus Zone corresponding to the Middle P. varcus Zone, it is quite possible that the Taghanice event occurs in Belgium just above the level of limestones with the last stringocephalids.</ABSTRACT>

5741 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Monatshefte 2005, 1: 46-64.</SOURCE>
5742 <ABSTRACT>The examination of the rugose corals assigned to Hadrophyllum

- orbigny (Middle Devonian of Asturias, NW Spain), shortly described and incompletely figured by Altevogt (1967), allows to confirm its generic assignment but a new species must be erected: *H. asturicum*. A critical review of the species referred to *Hadrophyllum* shows that the genus is only represented by two species, namely *H. orbigny* and *H. asturicum*. *H. asturicum* is the only representative of the genus in North Gondwana. Palaeobiogeographic relationships between eastern North America provinces of Laurussia and North Gondwana are attested by its occurrence.

5767 <SOURCE>Bulletin of Geosciences 81, 3: 151-162.
<http://www.geology.cz/bulletin/contents/art2006.03.151></SOURCE>
5768 <ABSTRACT>This paper describes a colonial rugose coral from the upper Emsian or lower Eifelian of Aviados (Provincia León, northern Spain). This colony, which has been figured as *Phillipsastrea torreana* (Milne-Edwards & Haime 1851) by Almela & Revilla (1950), belongs in fact to *Radiastraea arachne* Stumm 1937. It is the first reported occurrence of the genus *Radiastraea* from Europe, and an example of close palaeobiogeographical relationships between the Cantabrian Mountains and North America during the Emsian. *Cantabriastraea* Schroeder & Soto 2003 is probably only a marginal case of *Radiastraea* Stumm 1937. The lectotype of *Phillipsastrea torreana* var. *minuta* Almela & Revilla 1950 from the upper Emsian to lower Eifelian or upper Givetian of Aviados (Provincia León, northern Spain) is designated and described in detail. It is a subspecies of *Phillipsastrea torreana* (Milne-Edwards & Haime 1851) with 10-12 major septa and a tabularium diameter of 1.9-2.1 mm.</ABSTRACT>

- Givetium und tiefen Frasnium des Rheinischen Schiefergebirges (Devon; Sauerland / Bergisches Land).</TITLE>
5780 <SOURCE>Zitteliana B25: 39-116.</SOURCE>
5781 <ABSTRACT>Recent investigations in the eastern part of the Rheinisches Schiefergebirge indicate the existence of stratigraphically significant rugose coral assemblages which can in part also be used for interregional stratigraphic correlations (Belgium, France, Poland), as they display always a typical faunal succession. Accordingly, six coral associations at the genus level are established, which can be used for biostratigraphic correlation of coral bearing sequences. The composition of these faunas allow assignment of ages to reef complexes where conodonts or shelly faunas are virtually absent. Although some "index species" are useful to refine these correlations, it is not possible to establish true "coral-biozones" based on current data. [first part of an extensive abstract; taxonomic description covers 35 species, including 2 new species and one new subspecies: Hunanophrentis abnormis n.sp., Wapitiphyllum scaphense n.sp. and Phillipsastrea hennahi perforata n. ssp.]</ABSTRACT>

5806 <SOURCE>Acta Geologica Polonica 55, 2: 163-185.</SOURCE>
5807 <ABSTRACT>Massive phillipsastreid tetracorals similar to Phillipsastrea hennahii, defined as a Ph. hennahii species group, are characterized by reduced intercorallite walls (thamnasterioid or subthamnasterioid habit), by variable but generally good development of horseshoe dissepiments at the tabularium/dissepimentarium boundary, and by strongly deflected peripheral platforms at corallite margins. Seven species of the Ph. hennahii species group, mostly from the Givetian of southern Euramerica, Iberia and northern Gondwana, are reviewed. Two species, the Middle Givetian Phillipsastrea sobolewi (Rózkowska 1956) and the Late Givetian Phillipsastrea jachowiczi, a new species

- described herein, both from the Holy Cross Mountains (Poland) are described and illustrated. Also described from that area is *Phillipsastrea falsa* Coen-Aubert 1987 from the Upper Frasnian. </ABSTRACT>

'Haures Formation in Belgium.</TITLE>
- 5819 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de Belgique, Sciences de la Terre 73: 11-27.</SOURCE>
- 5820 <ABSTRACT>Disphyllum mcleani n.sp., Temnophyllum wellinense n.sp. and Pseudozaphrentis zamkowsae (Wrzolek, 1993) are described in detail and come from the Givetian Terres d'Haures Formation, on the south side of the Dinant Synclinorium. This subdivision belongs to the top of the Polygnathus heminasatus Zone and to the Lower P. varcus Zone. Temnophyllum wellinense is present at the base of the lithostratigraphic unit together with Argustastrea quadridgemina (Goldfuss, 1826) refigured herein. Disphyllum mcleani and Pseudozaphrentis zamkowsae have only been observed very sparsely, respectively in the middle and upper parts of the Terres d'Haures Formation. At its top occur already a few species characteristic of the lower part of the overlaying Mont d'Haurs Formation. The area located between Beauraing and Resteigne to the east of Givet is compared to that more eastern of Hotton where the Terres d'Haures Formation is thicker and richer in coral beds.</ABSTRACT>

- 5833 <ABSTRACT>A new and temporary accessible Upper Devonian outcrop in the Ferques area (Boulonnais, North of France), has allowed one to observe and sample the c term of the Pâtures Member of the Beaulieu Formation. The following species were collected and are briefly figured or described: Metripophyllum bouchardi Milne-Edwards & Haime, 1850, Catactotoechus ? variabilis Rohart, 1988, Disphyllum gradutum Tsien, 1970, Themnophyllum cf. majus Walther, 1928, Sinodisphyllum kielciense (Rozkowska, 1980), Macgeea gallica gallica Lang & Smith, 1935, Macgeea sp., Thamnophyllum kozlowski (Rozkowska, 1953). The age is Upper Devonian, Frasnian, lower part of the Palmatolepis punctata Zone.</ABSTRACT>

5844 <TITLE>Lower Devonian (Emsian) rugose corals from the Cantabrian Mountains, northern Spain.</TITLE>
5845 <SOURCE>Acta Palaeontologica Polonica 48, 4: 547-558.</SOURCE>
5846 <ABSTRACT>Two species of Lower Devonian rugose corals are described from the Cantabrian Mountains of Spain: Cantabriastraea cantabrica gen. et sp.nov. and Tabulophyllum bonarense sp.nov. The development of root- or buffer-like attachment structures ('rhizoid processes') in T. bonarense indicates adaptation to the soft substrate and supports corallite stabilisation. Because of their strongly everted calices and a corresponding arrangement of trabeculae, the colonies of the genus Cantabriastraea are assigned tentatively to the Paradisphyllinae, constituting the first record of the subfamily in Western Europe. Some specimens give information on colony-formation of this taxon, which is induced by strong lateral budding (nonparricidal increase) of a remarkable large and long-lasting protocorallite. 5871 <SOURCE>Senckenbergiana lethaea 79, 1: 119-129. [in memoriam Dr. Wolfgang Struve]</SOURCE>
5872 <ABSTRACT>The Middle Devonian rugose coral species Battersbyia varia (Schlüter 1889) is revised. Specimens recently regarded as conspecific belong to an undescribed species of Xystriphyllum, which is closely related to Xystriphyllum implicatum (Tsien 1969). This species should most probably be split into two subspecies (or morphotypes?) because of very different development of lonsdaleoid dissepiments and completeness of septa.</ABSTRACT>

5896 <TITLE>Tryplasma (Anthozoa, Rugosa) im Mittel-Devon der Eifel (Rheinisches Schiefergebirge, Deutschland).</TITLE>
5897 <SOURCE>Senckenbergiana lethaea 81, 1: 71-89.</SOURCE>
5898 <ABSTRACT>The genus Tryplasma Lonsdale 1845 with the species Tryplasma rohrensis n.sp. (family Tryplasmataceae Etheridge 1907) has been recorded from the middle and western European Middle Devonian for the first time. Tryplasma is widely distributed in the lowermost part of the coral-rich Niederehe Subformation (Eifelian, Ahrdorf Formation) of the Eifel Mountains. From investigation of the trabecular microstructure of the new species Tryplasma rohrensis in view of its taxonomic value and related terminology, the hitherto preferred idea of **Tryplasma rohrensis**; sensu Hill (1936) cannot be fully accepted and is instead contrasted with the concept of **Tryplasma rohrensis**; of some earlier authors. Microscopic analysis revealed identical acanthine characteristics in a species of the tabulate genus Syringocystis Deng 1966, thus suggesting a basic revision and reinterpretation of its systematic position. Syringocystis can clearly be compared with Tryplasma and so possibly classified as a rugose coral. The horizon with Tryplasma constitutes a sharp stratigraphical marker. Its horizontal distribution supports the isochronic correlation of the Niederehe reefal facies in the individual Eifel Synclines and, in addition, confirms the traditional dating of the stratigraphic boundary layers of the Ahrdorf and Junkerberg formations. There is no age relationship between the Antoniusbusch Reef near Rohr and the Boudersath Reef (Hollerberg) in the eastern Blankenheim Syncline, which belongs to the Nohn Formation. Regional analysis of Tryplasma occurrences indicates many biostratigraphical parallels between the Eifel region and the Russian Devonian provinces in Europe and Asia as well as Middle Devonian areas in China and Australia and points to certain paleogeographic connections.</ABSTRACT>

5910 <SOURCE>Geologica et Palaeontologica 35: 63-79.</SOURCE>
5911 <ABSTRACT>Some taxa of insufficiently known rugose corals are described from the Upper Givetian of Friesenrath and the Frasnian-Famennian boundary-beds near Werth in the Aachen Syncline: Tabulophyllum aff. cylindricum Walther 1928, Temnophyllum blacourti (Rohart 1988), Spinophyllum cf. spongiosum (Schlüter 1889), Macgeea recta (Walther 1928), Hexagonaria? sp. W, Frechastraea pentagona minima (Rózkowska 1953) and Frechastraea cf. carinata Scrutton 1968. Rugose corals are generally rare within this stratigraphical interval and thus are important records for the Aachen Syncline. In addition, clear faunistic relationships in regard to faunas known from France (Ferques) and Belgium are recognizable.</ABSTRACT>

5922 <TITLE>Korallenfauna und Fazies givetischer Kalksteinabfolgen (Cürten-/Dreimühlen-Formation) der Dollendorfer Mulde (Devon, Rheinisches Schiefergebirge / Eifel).</TITLE>
5923 <SOURCE>Senckenbergiana lethaea 81, 1: 111-133.</SOURCE>
5924 <ABSTRACT>The descriptive terms "Leperditien-Kalke" and "Klotzige Bank-Kalke" were introduced by Kräusel (1953) during the reinvestigation of the Dollendorfer Mulde and describe two lower Givetian limestone intervals, each of about 15 to 20 m thickness. As none of those limestones yield biostratigraphically relevant macrofaunas, the age of both deposits can be estimated only approximately, considering the position of both between the well correlated Cürten and Rodert Formations. Examination of the sections revealed four facies types, characteristic for a shallow marine, peritidal setting. The limestones are composed mainly of calcisphere ostracode wackestones or peloidal calcisphere-ostracod-packstones. Together with amphiporoid-floatstones they indicate lagoonal and restricted environmental conditions. Intercalated amphiporoid rudstones suggest temporarily more agitated water conditions. Remarkable thrombolitic bindstones occur with a partly stromatolitic fabric yielding coralloids and Algae of the genus Issinella Reitlinger 1954 and Jansella Mamet & Roux 1975. Deposition of several stromatolitic coral rudstone layers indicates a greater water depth with more open marine influence. Eleven taxa of rugose corals can be recognized. Most of those are related to small trochoid zaphrentids or charactophyllids, which were able to survive in the restricted conditions of a lagoonal environment. Common species are Glossophyllum sp. cf. schoupeii, Grypophyllum sp. and Sinodisphyllum sp.. Pseudozaphrentis intermissa n.sp. Schröder is described as a new species.</ABSTRACT>

5935 <TITLE>Famennian colonial Rugosa from southern Poland: recovery and extinction.</TITLE>
5936 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 285-290.</SOURCE>
5937 <ABSTRACT>After the Frasnian-Famennian extinction the colonial Rugosa disappeared almost entirely from the fossil record. New data indicate that during the Late Famennian radiation colonial Rugosa evolved rapidly within isolated areas and became an important component of coral assemblages of the southern Poland. The assemblages consist of surviving taxa (Smithiphyllum aff. imperfectum and 4 Famennian species of Scruttonia), homeomorphic taxa (2 species of Pseudoendophyllum) and one new Famennian genus (Heterostroton). The pattern of extinction and recovery of colonial Rugosa seems to have followed the following rule: survivors from the F-F crisis went extinct after the Famennian radiation (the D-C extinction), and the homeomorphic species, as well as new taxa, survived subsequent D-C extinction.</ABSTRACT>

5949 <SOURCE>Acta Geologica Polonica 51, 2: 109-120.</SOURCE>
5950 <ABSTRACT>The astogeny of three species of the amural rugosan genus Scruttonia coming from the Famennian so-called main limestone cropping out in Dzikowiec (the Middle Sudetes) is described. The colonies studied reveal cyclomorphic variation usually regarded as seasonal in nature. The character and shape of the colony as well as the character of the internal skeletal elements has been investigated to determine the colony-sediment interactions. The character of those interactions and the taphonomy of the colonies helped to make a determination of the colony growth rate and the sedimentation rate of the beds where colonial corals occur.</ABSTRACT>

5988 <SOURCE>Acta Geologica Polonica 31, 3-4: 169-174.</SOURCE>
5989 <ABSTRACT>The rugose coral Cyathophyllum diffusum sp.n. from the Upper Frasnian marly limestones of the Holy Cross Mts., Central Poland, is described. The new species has got dispersed trabeculae in the peripheral parts of the septa. Distally convex blisters, i.e. the intraseptal dissepiments, connect the dispersed trabeculae of a septum. Another type of intraseptal dissepiments is demonstrated in the species lowaphyllum mutabile Tsien 1977, from the Frasnian limestones of the same region; in this species the intraseptal dissepiments disrupt the continuity of the trabeculae and are the particular type of lonsdaleoid dissepiments</ABSTRACT>

6014 <SOURCE>N. Jb. Geol. Palaeont. Mh. 1982, 1: 648-666.</SOURCE>
6015 <ABSTRACT>Eine Bestandsaufnahme der im Mittel- und Oberdevonprofil der Bergisch Gladbach-Paffrather Mulde vorkommenden cerioiden, rugosen Blockkorallen erforderte eine Revision einiger in die Gattung Hexagonaria Guerich 1896 bzw. Disphyllum de Fromentel 1861 gestellten Arten. Viele dieser Arten lassen sich weder auf Hexagonaria Guerich noch auf Disphyllum de Fromentel beziehen. Deshalb war die Einfuehrung einer neuen Gattung (Pseudohexagonaria n.g.) erforderlich. Eine streng an der Typus-Art H. hexagona (Goldfuss 1826) orientierte Definition ergab, dass Hexagonaria Guerich im europaischen Devon auf die Frasn-Stufe (Oberdevon) beschraenkt ist. Im Arbeitsgebiet kommt nur die Typus-Art H. hexagona (Goldfuss) vor, und zwar in den Refrather Schichten. [A revision of some species attributed to Hexagonaria Guerich 1896 respectively Disphyllum de Fromentel 1861 shows that many of them must be referred to a new genus (Pseudohexagonaria n.g.). With a definition strictly related to the type-species (H. hexagona (Goldfuss 1826), Hexagonaria Guerich is restricted in Europe to the Frasnian (= Adorf-Stufe; U. Devonian). Only the type-species H. hexagona (Goldfuss) occurs in the Devonian sequence investigated].</ABSTRACT>

6065 <TITLE>Devonskie rugozy severa Urala.</TITLE>
6066 <SOURCE>Nauka, Leningrad: 120 pp., 58 pls.</SOURCE>
6067 <ABSTRACT>The work concerns the Rugosa - group of fossil [corals] important for stratigraphy of the Devonian of western slopes of Polar Urals and of Pay-Khoy. Described are 94 rugosan species of 57 genera, classified into 29 families; 2 families, 9 genera and 23 species are new and are based on the author's material. Analyzed are stratigraphic and geographic distribution of corals, and their ecology. Zonation pattern is established with assemblages characteristic of: * Ovinparm horizon of the Lochkovian; * Pragian and Zlichovian; * Koyven and Bia horizons of the Eifelian; * Afoniya and Cheslav horizons of the Givetian; * Lower, Middle and Upper substages of the Frasnian. 6078 <TITLE>Rugueux givétiens et frasnien de Ferques, Boulonnais - France.</TITLE>
6079 <SOURCE>Biostatigraphie du Paléozoïque 7 [BRICE D. et al. (eds)]: 231-296.</SOURCE>
6080 <ABSTRACT> partir des récoltes banc par banc, 39 espèces parmi les plus communes sont décrites et figurées dont 9 nouvelles et 4 laissées en nomenclature ouverte. L'étude historique montre que 2 seulement avaient déjà été citées dans le Boulonnais et que la plupart des 47 noms anciens attribués aux rugueux boulonnais jusqu'ici (tableau 1) doivent être abandonnés. La repartition stratigraphique est résumée dans le tableau 2. La série stratigraphique qui a livré des rugueux s'étend de la Zone à ensensis supérieure (Givétien) à la Zone supérieure à asymmetricus (Frasnien). Les Disphyllidés dominent tant en nombre d'espèces qu'en nombre d'individus. La plupart des formes possèdent une extension stratigraphique limitée comparable à celle qu'elles ont dans des régions voisines. Au Givétien, quelques espèces sont communes avec le Massif Schisteux Rhénan; au Frasnien, c'est avec l'Ardenne et la Pologne que l

on remarque les plus grandes affinités. Mais la valeur de ces observations est limitée par la connaissance incomplète que l'on a des faunes coralliennes européennes spécialement au Givétien et en Allemagne. La succession des faunes de rugueux, mise en évidence par Galle (1985), en Moravie, se retrouve en gros dans le Boulonnais au niveau générique mais les espèces typiques sont différentes. La partie systématique décrit les 39 espèces suivantes placées dans 22 genres en portant, chaque fois que cela est possible, une attention particulière à la variation et à la structure fine : *Lythophyllum secundum secundum* (Goldfuss 1826), *L. secundum conistructum* (Quenstedt 1879), *L. secundum pseudoseptatum* (Schulz 1883), *Mesophyllum cristatum* (Schlueter 1882), *Metrioplexus richteri* Glinski 1963, *M. sp. cf. carinatus* Rozkowska 1969, *Catactotoechus variabilis* n.sp., *Tabulophyllum smithi* Tsien 1976, *T. sylvaticum* n.sp., *T. vorticis* n.sp., *Acanthophyllum concavum* (Walther 1928), *Ellesmerelasma* ? sp. cf. *diluvianum* (Wedekind 1925), *Stringophyllum isactis* (Frech 1886), *Gaofengophyllum cf. longiseptatum* (Bulvanker 1958), *Columnaria* ? sp. cf. *junkerbergiana* Glinski 1955, *Disphyllum rugosum* (Wedekind 1922), *D. pashiense* (Soshkina 1939), *D. lazutkini* (Ivaniya 1953), *D. gradatum* Tsien 1970, *D. grabau* Tsien 1970, *Pseudohexagonaria amanshauseri* (Glinski 1955), *P. glinskii* (Tsien 1977), *Disphyllia wangi* (Tsien 1977), *D. hamoriensis* (Tsien 1977), *D. periclada* (Kraemer 1982), *D. magnei* n.sp., *Aristophyllum lemaitreae* n.sp., *Hexagonaria marmini* (Milne-Edwards et Haime 1851), *H. mirabilis* Moenke 1954, *Hexagonaria mae* Tsien 1977, *H. mireillae* n.sp., *Cystohexagonaria defecta* n.sp., *Temnophyllum longiseptatum* (Luetze 1984), *Truncicarinulum blacourti* n.sp., *Thamnophyllum caespitosum* (Goldfuss 1826), *T. kozłowski* (Rozkowska 1953), *Peneckiella fascicularis* (Soshkina 1939), *Cyathophyllum briceae* n.sp. et *Spinophyllum arduum* (Luetze 1985). 2 genres inconnus en Europe jusqu'ici sont cités: *Ellesmerelasma* ? et *Gaofengophyllum*. *Cystohexagonaria* nov. gen. est établi.

6091 <TITLE>Rozkowskaella, a new name for Devonian tetracoral *Trigonella* Rozkowska, 1980.</TITLE>
6092 <SOURCE>Acta Palaeontologica Polonica 31, 3-4: 277. [imprint 1985]
</SOURCE>
6093 <ABSTRACT>Rozkowska (1980) established the genus *Trigonella* for a Frasnian tetracoral from the Swietokrzyskie Mts. (= Holy Cross Mts., Poland), choosing as the type species *T. sandaliformis* Rozkowska 1980. The name was subsequently used by Hill (1981: F740). Professor Jerzy Fedorowski has drawn my attention to the fact that the name *Trigonella* has been preoccupied for a modern bivalve by da Costa 1778 (fide Moore 1969: N595). Therefore, I propose the new name *Rozkowskaella*, in honour of late Maria Rozkowska, an eminent Polish student of *Rugosa*. The type species and its type specimen remain the same, as it was indicated by Rozkowska (1980: 24, fig. 4, pl. 2: 6 a-c) [full text].</ABSTRACT>

6171 <ABSTRACT>The present paper deals with the description of four species of Glossophyllum Wedekind 1924 from the Middle Devonian of the Rhenish Massif (Eifel District). One of these, the Lower Givetian Glossophyllum soetenicum (Schlueter 1885), is revised and a lectotype is chosen. The Middle Givetian Glossophyllum ceratites (Goldfuss 1826) is also documented and Glossophyllum sp. A and Glossophyllum sp. B are described for the first time from the Middle Givetian Kerpen Formation of the Soetenich syncline (N Eifel).</ABSTRACT>

6247 <TITLE>Nouvelles especes du genre Phillipsastrea d'Orbigny, 1849 (Rugosa) dans le Givetien superieur de la Rade de Brest (Massif Armoricaïn, France).</TITLE>
6248 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Sciences de la Terre 77: 63-75.</SOURCE>
6249 <ABSTRACT>Two new species of rugose corals, namely Phillipsastrea kergarvanensis n.sp. and P. morzadeci n.sp., are described in detail and have been collected at Kergarvan in Plougastel-Daoulas lying in the Rade de Brest, at the western border of the Median Synclinorium, Armorican Massif, France. They come from the lower to the middle part of the Kergarvan Formation which belongs to the Upper Givetian, in the Schmidtognathus hermanni-Polygnathus cristatus conodont Zone. This discovery completes the palaeobiogeographic distribution of the genus Phillipsastrea d'Orbigny, 1849 that occurs in the Upper Givetian as an ubiquitous taxon, though well established at the North Gondwana and South Laurussia margins.</ABSTRACT>

6260 <TITLE>Spinophyllum wedekind, 1922 (Anthozoa, Rugosa) in the Lower Givetian (Devonian) of Bohemian Massif.</TITLE>
6261 <SOURCE>Bulletin of Geosciences 82, 2: 133-144.</SOURCE>
6262 <ABSTRACT>The rugose coral genus Spinophyllum wedekind, 1922 occurs in Moravia (S. conicum Kettnerová, 1932 and S. ondra sp.nov.). Its most peculiar character is coarse septal trabeculae displaying double bend of charactophyllids. In this, it resembles Charisphyllum Oliver & Sorauf, 1988, synonymized with Spinophyllum. Spinophyllum sp. cf. conicum Kettnerová, 1932 known from Koněprusy Acanthopyge Limestone of Prague Basin has its slender septal trabeculae arranged in half-fan or asymmetrical fan and do not belong to Spinophyllum. The fine structures of rugose corals are repeating at the same taxa in various preservational environments. It seems to prove that these fine

structures are at least based on the structures which originated through the life of corals. The mentioned fine structures were considered important diagnostic feature in the present paper. </ABSTRACT>

6325 <TITLE>Representants des genres Sociophyllum Birenheide 1962 et Beugniesastraea n.gen. a la base du Calcaire de Givet de Pondrome et de Resteigne (bord sud du Bassin de Dinant, Belgique).</TITLE>
6326 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Sciences de la Terre 68: 5-31.</SOURCE>
6327 <ABSTRACT>Spongophyllum kunthi Schlueter 1880, type species of the genus Beugniesastraea n.gen. has been sampled at the base of the Givet Limestone from Resteigne, with B. parvistella (Schlueter 1882). In this locality and at Pondrome, Sociophyllum elongatum (Schlueter 1881), S. torosum (Schlueter 1881) and S. birenheidei n.sp. occur in the same level. Four of these taxa characterize the Looch Formation, at the base of the Givetian from the Eifel Hills in Germany. The Couvinian species Beugniesastraea varia (Schlueter 1889) is also described.</ABSTRACT>

6338 <TITLE>Middle / Upper Devonian boundary coral stratigraphy in the Rhenish Mountains of W Germany.</TITLE>
6339 <SOURCE>Canadian Society of Petroleum Geologists, Memoir 14 [McMillian N. J., Embry A. F. & Glass D. J. (eds): Devonian of the World], III: 141-145.</SOURCE>
6340 <ABSTRACT>Since investigations of Frech (1885, 1886), Paeckelmann (1913) and Walther (1928), only sporadic work has been done on the coral faunas of the Middle / Upper Devonian boundary beds of the Rhenish Mountains. Recent studies based on new material mainly collected by the author yielded the following results: whereas rugose corals of the upper Givetian time-equivalent Kerpen, Buechel and Schwelm Formations are relatively abundant and well known also at comparable stratigraphic levels all over the world, they become rare in uppermost Givetian and lowermost Frasnian beds. Such units are represented in W. Germany by the Wallersheim Formation (Eifel hills), the Grenzschiefer; (Walheim, near Aachen), the Plattenkalk; (Upper Bergisch Land), and the Flinz; and Dorp Limestones (Lower Bergisch Land, Sauerland). These transitional units with thickness of more than one hundred metres at some localities contain rugose corals which proved to be Middle / Upper Devonian mixed faunas; moreover there is some difference between the coral faunas of the lower and upper parts of the transitional successions. In the lower parts corals of the Middle Devonian genera Acanthophyllum, Grypophyllum and Battersbyia (or Fasciphyllum) are still present, whereas stringophyllids are entirely lacking. Temnophyllum and allied forms as well as different caespitosans; also occur, but seem to be of little stratigraphic value for a boundary discrimination. In the Lower Plattenkalk; we also meet the last (?) representatives of Disphyllia and the first specimens of probably Wapitiphyllum. At other

outcrops which apparently represent the middle part of the transitional succession, a more or less mixed fauna is present; the previously mentioned genera are still recorded, but now more Upper Devonian elements appear for the first time, with rare specimens of *Tabulophyllum sensu stricto* (broad tabularium, no fossula) and of *Pexiphyllum*. Finally, in outcrops of the upper parts of the transitional beds the first representatives of the massive coral species *Hexagonaria hexagona* (= *sedgwicki* of Paeckelmann), *Phillipsastrea hennahi* and *Frechastraea sanctacrucensis* occur, accompanied by small as well as large specimens of *Pexiphyllum*. These upper parts often contain brachiopods and sometimes also trilobites of Upper Devonian character. But we also found in them the very last representatives (one specimen respectively) of the Middle Devonian genera *Acanthophyllum* (probably n.sp.) and *Cystiphyllodes*.</ABSTRACT>

- summary] </SOURCE>
- 6379 <ABSTRACT>From different localities of the Middle Givetian (Middle Devonian) of the Rheinische Schiefergebirge the following species of rugose corals are described: Spinophyllum spongiosum (Schlueter 1889), Mictophyllum schlueteri n.sp., Temnophyllum cf. ornatum Walther 1928, Disphyllum sp., Grypophyllum denckmanni Wedekind 1922, Grypophyllum postprimum n.sp. (with two subspecies), Acanthophyllum sp. of the group vermiculare / concavum, Mesophyllum (Mesophyllum) vesiculosum cf. vesiculosum (Goldfuss 1826) and Mesophyllum (Cystiphyllodes) secundum secundum (Goldfuss 1826). A lectotype is designated for Spinophyllum spongiosum, and the morphological variability of this species is demonstrated by means of thin section figures. The occurrence of the genus Mictophyllum Lang & Smith 1939 in W. Germany is recorded for the first time.</ABSTRACT>

- 6405 <ABSTRACT>Since the investigations of Frech (1885, 1886), Paeckelmann (1913) and C. Walther (1928, 1929), only sporadic work has been done on the coral faunas of the Middle/Upper Devonian boundary beds of the Rheinische Schiefergebirge. Recent studies, mainly based on new material, have yielded the following results. Whereas rugose corals of the Middle Givetian, roughly time-equivalent Kerpen, Buechel and Schwelm Formations are relatively abundant and well-known, also from comparable stratigraphic levels nearly all over the world, they become rare in uppermost Givetian and lowermost Frasnian beds. Such units are represented in W. Germany by the Wallersheim Formation (Eifel hills, Pruem Syncline), the Grenzschiefer beds (Walheim, near Aachen), the Plattenkalk and Hornstein levels (Bergisches Land), as well as the Flinz and Dorp Limestones (N. Bergisches Land and

Sauerland). These transitional units, which are more than one hundred metres thick at some localities, contain rugose corals which proved to be Middle/Upper Devonian mixed faunas; moreover, there is some difference between the coral faunas of the lower, middle, and upper parts of the transitional successions. In the lower parts, corals of the Middle Devonian genera *Acanthophyllum*, *Grypophyllum*, and *Battersbyia* (or *Fasciophyllum*) are still present, whereas *Stringophyllum* is entirely lacking. *Temnophyllum* and allied forms, as well as different *Disphyllum* (*Disphyllum*) colonies of the caespitosum species group (with a tendency to *Temnophyllum*-like septal structures) also occur, but they seem to be of little stratigraphic value for a boundary discrimination. In the Lower Plattenkalk of the Paffrath Syncline the last (?) representatives of *Disphyllia* and the first (?) specimens of the genus *Wapitiphyllum* occur. At other outcrops which apparently represent the middle part of the transitional succession there is a more or less mixed fauna: the genera cited above are still recorded, but some characteristic Upper Devonian faunal elements appear for the first time with rare specimens of *Tabulophyllum* s. str. (with broad tabularium and without fossula), and of *Pexiphyllum*. Finally, in outcrops of the upper parts of the transitional beds, the first representatives of the massive coral species *Hexagonaria hexagona* and the (sub)genera *Phillipsastrea*, *Frechastraea* (*Scruttonia*) and *Haplothecia* (*Kuangxiastraea*) occur, accompanied by both small and large specimens of *Pexiphyllum*, and at the level of the "Grenzschiefer" beds of Walheim even a representative of the Chinese subgenus *Disphyllum* (*Pseudodisphyllum*) is recorded. These upper parts often contain brachiopods and sometimes also trilobites of distinctly Upper Devonian character, however, the very last representatives (one specimen respectively) of the Middle Devonian genera *Acanthophyllum* (probably a new species) and *Cystiphyllodes* also occur. </ABSTRACT>

- 6431 <ABSTRACT>Twenty taxa of cornute and conical rugose corals are described from Middle Devonian deposits of the Eifel district, mainly from the Givetian of the Soetenich syncline (north Eifel, Rhenish Massif). The corals belong to the families Cyathaxoniidae, Cystiphyllidae, Hapsiphyllidae, Ptenophyllidae and Cyathophyllidae, and the following species are new: Cyathophyllum (Cyathophyllum) trochiforme, Soetenia struvei, Mictophyllum duesterbergense, Glossophyllum varioseptatum, Glossophyllum schoupepei, Glossophyllum dachsbergense and Schlueteriphyllum parvum. A lectotype is designated for Adradosia incurva (Schlueter 1884). The stratigraphic distribution of the described species is discussed and the evolution of the family Cyathophyllidae is reviewed.</ABSTRACT>

6495 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Sciences de la Terre 61: 5-19.</SOURCE>
6496 <ABSTRACT>The discovery of horseshoe dissepiments at the base of some coralla of Trigonella sandaliformis Rozkowska 1980, type species of Rozkowskaella wrzolek 1987 from the Upper Frasnian of Poland, leads to consider this taxon as subgenus of Macgeea Webster 1889. Moreover, Debnikiella Rozkowska 1980, whose type species is D. formosa Rozkowska 1980 also from the Upper Frasnian of Poland, can probably be placed in synonymy with Rozkowskaella. For comparison, a few topotypes of Pachyphyllium solitarium Hall & Whitfield 1873, type species of the genus Macgeea are described.</ABSTRACT>

de la Belgique.</TITLE>
- 6521 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de
Belgique, Sciences de la Terre 65: 35-49.</SOURCE>
- 6522 <ABSTRACT>Four species of *Peneckiella* Soshkina, 1939 are recorded in the
middle part of the Frasnian. In the Philippeville Massif, *P. isylica*
(Bulvanker, 1958) and *P. fascicularis* (Soshkina, 1939) have been
collected in the lower part of the Philippeville Formation. The latter
species also occurs on the south side of the Dinant synclinorium: at
the base of the Bieumont Member in the Focant borehole and in the Lion
Member of North Quarry at Frasnies-les-Couvin. *P. duponti* n.sp. is
abundant in the intercalations of red marble located at the base of
this exposure whereas *P. szulczewskii* Rozkowska, 1979 has been found at
the base of the Boussu-en-Fagne Member. Several of these species are
associated with *Hexagonaria mirabilis* Moenke, 1954, *Scruttonia balconi*
Coen-Aubert, 1980 and *S. focantiensis* (Tseen, 1978) senior of *S.*
boloniensis minor Coen-Aubert, 1980.</ABSTRACT>

Mulde.</TITLE>
- 6534 <SOURCE>Senckenbergiana letaea 75, 1/2: 33-75.</SOURCE>
- 6535 <ABSTRACT>A rugose coral fauna from the Upper Eifelian (Freilingen
Formation) of the Dollendorf Syncline (Eifel Hills/Rheinisches
Schiefergebirge) has been investigated. All corals originated from an
abandoned outcrop located in the Ahr Valley, NE Dollendorf Syncline.
The determination of the coral species resulted in a relatively high
number of different species which usually characterize Eifelian strata
of the Eifel but were only rarely known from the Freilingen Formation.
A remarkable discovery was a new species of *Heliophyllum*, herein
described as *Heliophyllum* (*Heliophyllum*) *holleri* n.sp., a close
relative of which is *Heliophyllum* (*Moravophyllum*) sp. Because of this
relationship the genus *Heliophyllum* has been subdivided now into the two
subgenera *Heliophyllum* (*Heliophyllum*) and *Heliophyllum* (*Moravophyllum*).

6548 <ABSTRACT>The study of rugose corals allows to date a few coral levels from the Frasnian of the Focant borehole which has reached the depth of 3208m, on the south side of the Dinant Synclinorium. These fossils occur mainly in the Grands Breux Formation, in the middle part of the stage. *Scruttonia focantiensis* (Tsien, 1978), *Hexagonaria mirabilis* Moenke 1954, *Macgeea brevissepta* (Picket, 1967) and *Peneckiella fascicularis* (Soshkina, 1939) are the principal species of the Bieumont Member whereas *P. szulczewskii* Rozkowska, 1979 has been found in a faulted zone of the Boussu-en-Fagne Member. Interesting facies variations appear also in the Bieumont Member which has been intersected several times.</ABSTRACT>

6560 <SOURCE>Geologica et Palaeontologica 30: 15-31.</SOURCE>
6561 <ABSTRACT>The Siphonophrentidae Merriam 1974 are recorded with a new species of the genus *Enallophrentis* from the Devonian of the Eifel / Rhenish Mountains. Siphonophrentids are group of formerly endemic genera of the Eastern Americas Realm [EAR], and their distribution in the Eifel can be proved for the first time. *Enallophrentis rhenana* n.sp. was collected in the Freilingen Formation (Middle Devonian, Upper Eifelian) of the Dollendorf Syncline (Eifel) and is regarded as an example for faunal migration from the EAR into the Eifel which can be recognized especially in the Upper Eifelian. As the stratigraphic distribution of this new species is confined to the Freilingen Formation, it is useful for biostratigraphic correlation at least in the Northern Eifel.</ABSTRACT>

- 6574 <ABSTRACT>The stromatoporoid reef limestone that outcrops in the Fondry des Chiens at Nismes, reaches a thickness of 70 metres and is assigned to the base of the Givetian, by conodonts. It contains rare colonies of Neomphyma dalcqae n.sp. and Fasciphyllum katranicum (Gorianov 1968). F. conglomeratum (Schlueter 1881), type species of Fasciphyllum Schlueter 1885 has been collected from the Upper Eifelian and Lower Givetian of wellin. The relations between the genera Fasciphyllum and Battersbyia Milne-Edwards & Haime 1851 are also investigated.</ABSTRACT>

- 6586 <SOURCE>Palaeontographica A221, 4-6: 95-123.</SOURCE>
- 6587 <ABSTRACT>From four outcrops of the Portilla Fm. and one outcrop of the Candás Fm. in the W Cantabrian Mountains 17 species and subspecies of solitary and phaceloid rugose corals are described. They belong to 15 different genera. The stratigraphical classification of four of the localities in question as Upper Givetian is confirmed by means of the identified coral faunas, and this age is also probable for the fifth locality. The rugose coral genera Brevisseptosia n.gen. and Sinaxis n.gen. are erected in this paper, moreover the following 13 new species and subspecies are described and figured: Schindewolfia plena n.sp., Neaxon variabilis n.sp., Catactotoechus bonarensis n.sp., Metrionaxon transitorius n.sp., Famennelasma antiquum n.sp., Brevisseptosia pulchra n.gen. et n.sp., Sinaxis bulbosa n.gen. et n.sp., Cyathophyllum (C.) postarduum n.sp., Thamnophyllum caespitosum leonense n.ssp., Acanthophyllum confusum n.sp., Stringophyllum buechelense cantabricum n.ssp., Stringophyllum crassimargjnatum n.sp. and Soliptera fontainei n.sp. The number of genera and species of the normally as ahermatypic classified small solitary corals without dissepimentarium is unusually great with respect to the reef facies of the Portilla Formation. A part of them even occurs together with compact flat colonies of back reef corals of the subfamily Phillipsastreinae. Moreover at other localities such small corallites also occur together with aggregates of cylindrical corals of the "reef meadows" or even together with large solitary corals. So we have to assume that the "Portilla environment" of the investigated localities was characterized by a very narrow-spaced irregular morphological pattern of its sea bottom.</ABSTRACT>

6625 <SOURCE>Courier Forschungsinstitut Senckenberg 164: 103-108. [P. Oekentorp-Kuster (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 1]</SOURCE>
6626 <ABSTRACT>The traditional Eifelian / Givetian boundary is defined by the first occurrence of the brachiopod genus Stringocephalus (boundary sensu Beyrich 1837; Struve 1961). In the Eifel Hills this boundary is located between the Upper Eifelian Ahabach and the Lower Givetian Loogh Formation. In the light of actual discussions of new definitions by means of conodonts, the distribution of rugose corals has been investigated within this stratigraphic range. In the northern Eifel Hills the Upper Eifelian is not characterised by a typical association of rugose corals. Many of the well known genera and species show a long stratigraphic range and some of them are still common in the Lower Givetian. Only a few taxa become extinct at the top of the Ahabach Formation. In the Lower Givetian the composition of the coral association changed, caused by the appearance of new taxa. The association is now dominated by small cornute corals (e.g., Schlueteriphyllum looghiense, Sch. parvum, Soetenia struvei, Aristophyllum terechovi) as well as Glossophyllum soetenicum. From the point of coral development the traditional Eifelian/Givetian boundary represents a crisis in the northern Eifel Hills. The boundary is not based on the extinction of many species, but is reflected by the appearance of the Schlueteriphyllum - Glossophyllum - Association in the Lower Givetian.</ABSTRACT>

- 6639 <ABSTRACT>Described and illustrated are over 40 colonies of *Phillipsastrea lacunosa* from the Upper Frasnian smithi Zone of the Holy Cross Mountains, Poland. The corals are phaceloid to pseudocerioid, with thick internal septothecae surrounding tabularia; the latter are without septa. 3 subspecies are distinguished within the material studied: *Ph. lacunosa lacunosa* (Guerich), predominantly phaceloid, with gently concave tabulae; *Ph. lacunosa smithi* (Rozkowska), typically pseudocerioid, with larger corallites; *Ph. lacunosa mariae* subsp. n., morphologically intermediate between the former subspecies, with tabulae commonly flat. Distinction of subspecies rather than species is justified by presence of forms intermediate between these three morphotypes.</ABSTRACT>

- 6664 <SOURCE>Acta Palaeontologica Polonica 37, 2-4: 217-254.</SOURCE>
- 6665 <ABSTRACT>Rugose corals of the Givetian to Lower Frasnian Kowala limestone Formation in the environs of Checiny, SW Holy Cross Mts and in its age equivalents in the Silesian-Cracow region of Southern Poland represent five distinct assemblages of restricted time-and-space distribution. Within the Stringocephalus Beds the high diversity *Pseudohexagonaria(?) laxa* assemblage indicates open-shelf conditions whereas low diversity *Temnophyllum occidentale* assemblage represents restricted conditions. The transgressive Jazwica Mbr. locally contains diversified and cosmopolitan *Acanthophyllum* sp. n. fauna. Following temporally coral assemblages, i.e. *Disphyllum* (lower Sitkówka and Checiny Beds) and *Macgeea-Thamnophyllum* (Kadzielnia Mbr, upper Sitkówka Beds) are mostly biostromes of branching corals of low taxonomical diversity typical for relatively restricted setting, rather unfavorable

- for rugosans. Exceptional are two Hexagonaria horizons with common massive colonies. *Diffusolasma* gen. nov., *Sociophyllum severiacum* sp. nov., *Temnophyllum zamkowae* sp. nov. and *Hexagonaria hexagona kowalae* subsp. nov. are proposed as the new taxa. </ABSTRACT>

 6729 <SOURCE>Geologica et Palaeontologica 31: 1-36.</SOURCE>
 6730 <ABSTRACT>As a further contribution to the knowledge on the Upper Eifelian coral fauna of the Dollendorf syncline the rugose corals of the Eilenbergian (Freilingen Formation) are investigated. The fauna comprises 20 different species; three of them are new: Spinophyllum incompositum n.sp., Chostophyllum dollendorfense n.sp. and Grypophyllum duplex n.sp. The insufficiently known and often misinterpreted species Kunthia crateriformis is revised. In spite of the fact that corals are generally very rare in the brachiopod-dominated facies of the Eilenberg Member, the fauna shows a remarkable high diversity and is characterized mainly by small trochoid coral species. Next to some well known genera of the Middle Devonian of the Eifel some species restricted to Upper Eifelian strata and also species known as ahermatypical have been found. Additionally, two genera typical for the eastern North American faunal realm were recorded. The distributional patterns of some species are discussed, especially in regard to the so called Gliniski-Linie, which marks a border for faunal exchange between the North- and South-Eifel in the Dollendorf syncline.</ABSTRACT>

6743 <ABSTRACT>Acanthophyllum tortum (Tsien 1969), Thamnophyllum germanicum Scrutton 1968, T. occlusum (Tsien 1969) and T. tsieni n.sp. are described in detail and have been mainly collected at Pondrome, Wellin and Resteigne. The type specimens from several of these species as well as the holotype of Acanthophyllum vermiculare (Goldfuss 1826) are refigured herein. Thamnophyllum germanicum has been found at the top of the Jemelle Formation. T. tsieni and T. occlusum also occur at the top of this lithostratigraphic unit, but are particularly abundant in the Hanonet Formation; moreover, T. occlusum is still present at the base of the Trois-Fontaines Formation. Acanthophyllum tortum is characteristic of the Hanonet Formation, but has also been observed in the X Formation and at the base of the Trois-Fontaines Formation. Finally, the new geological surveys near Wellin confirm the lateral changeover from the base of the Trois-Fontaines Formation to the Hanonet Formation.</ABSTRACT>

6768 <SOURCE>Coral Research Bulletin 05: 211-220.</SOURCE>

- 6769 <ABSTRACT>The rugose corals from the Boudersath-reef and the Holler-Berg in the Frohngau-Engelgau part of the Blankenheim Syncline have been investigated. The poor rugose coral-fauna is characterized by a relatively low number of species: Acanthophyllum heterophyllum, Stringophyllum cf. acanthicum, Sociophyllum elongatum, Mesophyllum (Mesophyllum) pseudoorthoceras, Mesophyllum (M.) cf. cylindricum. Therefore a comparison with other localities of *Sociophyllum elongatum* in the Niederehe-reefs of the Ahrdorfian is impossible. With the occurrence of *Sociophyllum elongatum* the stratigraphic range of this species in the Eifel Hills will be considerably extended.</ABSTRACT>

- 6780 <TITLE>Strunian corals - examples from Poland (in Polish with English summary).</TITLE>
- 6781 <SOURCE>Geologos 1: 69-78.</SOURCE>
- 6782 <ABSTRACT>The Strunian, due to its facial character, has no significant chronostratigraphical or geochronological value. This term, however, is widely used by coral researchers because it denotes its own, characteristic coral fauna. During the crisis at the Frasnian / Fammenian boundary, a variable and rich coral fauna became strongly depleted. It was not until after the crisis, that in the zones rhomboidea and marginifera, first evolutionary impulse occurred, and after a transgression in the expansa chron, a strong development of two *Sociophyllum*-groups of corals took place: (1) corals of basin facies (fauna of the *Cyathaxonia* type), (2) corals of shallow shelf facies, the so called *Strunian corals*; (fauna of the *Canino-Clisiophyllum* type). Corals of colonial type described lately as *Calyxcorallia* Fedorowski, 1991, in particular, should also be recognized as *Strunian* corals. In Poland, three areas exist of coral occurrence in the Late Fammenian, i.e.: the Swietokrzyskie Gory Mts, the Sudetes and the Krakow region. Preliminary investigation of coral faunas of these areas allows distinguishing of two regions: 1. Swietokrzyskie Gory Mts region, where coral fauna typical of basin facies occurs; however, in the southern part of this region (Kowala locality) Strunian fauna of the *Canino-Clisiophyllum* type is also present. The fauna can be traced along the belt of outcrops from the Ardennes, through the Thuringen to the Swietokrzyskie Gory Mts. 2. The region of the Sudetes and the Krakow region, where an exceptional fauna of colonial corals occurs, which is typical of shallow shelf zone; its counterparts are known from China only.</ABSTRACT>

6807 <SOURCE>Bulletin de l''Institut royal des sciences naturelles de Belgique, 69: 27-46.</SOURCE>
6808 <ABSTRACT>The Mont d''Haur Formation, which belongs to the Lower Polygnathus varcus Zone, reaches a thickness of about 180 metres between Beauraing and Han-sur-Lesse, on the south side of the Dinant Synclinorium. Argutastrea tenuiseptata Coen-Aubert & Luetze, 1990, Sociophyllum isactis (Frech, 1886) and S. wedekindi n.sp. are characteristic of its lower part whereas Sunophyllum beichuanense He, 1978, Argutastrea wangi (Tsien 1978) and Wapitiphyllum laxum (Guerich 1896) occur in its upper part. Moreover, the latter species is still present at the base of the overlying Fromelennes Formation. Sociophyllum isactis, S. wedekindi and Sunophyllum beichuanense are described in detail. A neotype is proposed for Wapitiphyllum laxum, the neotype of Sociophyllum isactis is revised and refigured.</ABSTRACT>

6819 <TITLE>Lower Devonian (Emsian) Rugosa of the Izarne Formation, Montagne Noire, France.</TITLE>
6820 <SOURCE>Journal of Paleontology 72, 6: 967-991.</SOURCE>
6821 <ABSTRACT>An account of the systematics, biostratigraphy, ecological setting and the biogeographic implications of rugose corals from olistoliths of the Cabrieres area is given. Corals of the lower member of the Izarne Formation are dated by conodonts as Gronbergi Zone age, and include Lythophyllum sp. indet., Calceola sandalina (Linne), Tryplasma sp. A, Breviphrentis roharti Pedder new species, B. exigua Pedder new species, and Aqishaphyllum sp. A. Corals from the middle member of the formation include Frechocystis pertinax Pedder new genus and species, Calceola sp. undet, Rhizophyllum sp. aff. R. ukalundense Flinck and Jell, Tryplasma enorme Pedder new species, Tryplasma sp. A, Breviphrentis sp. A, Platysmatophyllum halleri Pedder new genus and species, Pseudochonophyllum sentum Pedder new species, and Izarneophyllum barroisi (Frech) new genus. No age significant conodont has been recovered from the middle member. However, scutellid trilobites, which, together with other trilobites, evidently used the underside of Izarne corals for shelter during molting, provide correlation with conodont sequences in the nappe domain to the north and southwest of Cabrieres. From this line of evidence, the middle Izarne coral fauna is deduced to be Nothoperbonus Zone in age. The association of a variety of benthic trilobites, all with large eyes, provides evidence of a photic zone environment for the middle Izarne corals. Rugose corals from the Izarne Formation belong to the Old World Realm and have nothing in common with similar age Rugosa of the Eastern

- Americas Realm. This implies that the dissolution of the boundary between these realms, which occurred in the Middle Devonian, did not begin before latest Emsian time.

- 6833 <SOURCE>Courier Forschungsinstitut Senckenberg 208: 135 pp.</SOURCE>
- 6834 <ABSTRACT>The distribution of several fossil groups from the Middle Devonian of the Eifel region suggest that it may be subdivided into three faunal regions; (North-, west-and South-Eifel). These regions are widely accepted in the literature, and the boundary between the N and S Eifel regions, which has become known as the Glinzische Linie, traverses the Dollendorfer Mulde in an E-W direction. Due to its central position in the Eifeler Kalkmuldenzone, the Dollendorfer Mulde is important in the recognition of Devonian faunas within the Eifel. Several taxa of brachiopods and corals are known as characteristic faunal elements of the northern Eifel and their southward distribution seems to end exactly at the Glinzische Linie. However, the geology of the Dollendorfer Mulde is not adequately known, and consequently a detailed taxonomic-systematic study of its fossil content has not been undertaken. As a result detailed comparison with other Eifel synclines is currently impossible. [first part of extensive summary].</ABSTRACT>

- 6847 <ABSTRACT>Ten species belonging to the genera Hexagonaria Guerich 1896, Aristophyllum Bulvanker, Spassky; Kravtsov 1975, Phillipsastrea d'Orbigny 1849, Frechastraea Scrutton 1968, Scruttonia Tcherepnina 1974, Peneckiella Soshkina 1939 and Trapezophyllum Etheridge 1899 including T. roharti n.sp. are described and figured. This material comes mainly from the Boussu-en-Fagne Member and the Neuville Formation exposed at Frasnes, Boussu-en-Fagne and Nismes. The geological surveys emphasize interesting lateral facies variations close to the second and third levels of Frasnian bioherms. The correlations with the Philippeville Massif are also considered. The investigated fauna shows strong affinities with that from the Boulonnais in France and the Holy Cross Mountains in Poland.</ABSTRACT>

Devonian, Barrandian, Czech Republic).</TITLE>
6872 <SOURCE>Vestnik Ceskeho geologickeho ustavu 69, 1: 41-58.</SOURCE>
6873 <ABSTRACT>The Eifelian Acanthopyge Limestone with the well documented
conodont zones Po. costatus partitus up to Po. hemiansatus of the
Barrandian Koneprusy area yielded diverse rugosan faunas. Seventeen
species belonging to eleven genera were recorded. The assemblage
differs from corals of the same age found in Moravia, nevertheless,
most of the taxa of both regions can be compared with corals from the
German Rhenish Slate Mountains. Bohemian Eifelian Rugosa show striking
similarities to Givetian faunas of other regions.</ABSTRACT>

Angustiphyllum Altevogt (Coelenterata, Rugosa) del Devónico medio de la
Cordillera Cantábrica (NO de España).</TITLE>
6885 <SOURCE>Revista Española de Paleontología 01: 63-72.</SOURCE>
6886 <ABSTRACT>The genus Angustiphyllum Altevogt, of a marked provincialism,
is represented in the Middle Devonian (Eifelian) of the Cantabrian
Mountains by species, whose most striking feature is its outer wedge
shaped aspect. The only species, A. cuneiforme Altevogt, shows apart
from this morphology other typical characteristics of the genus, such
as an axial ridge, formed by synapticalae arranged perpendicularly to
the cardinal-counter plane and septa consisting of fibrolamellar
microstructure. In this work the systematic value of both
characteristics is analyzed and on that basis the diagnosis of the
genus Angustiphyllum is enlarged. Its systematic position, concerning
family and subfamily, is discussed as well. Likewise, the geographical
distribution of the genus in the Cantabrian Mountains is extended so
that it constitutes a useful guide-level on a regional scale. The
finding of similar specimens of Angustiphyllum, but lacking the axial

- ridge in the calice, makes it possible to propose a new genus and species, but for the moment we prefer to keep them in open nomenclature because of the small number of specimens collected. </ABSTRACT>

- 6924 <SOURCE>Muenstersche Forschungen zur Geologie und Palaeontologie 77: 373-421. [in German, with English abstract].</SOURCE>
- 6925 <ABSTRACT>A rugose coral-fauna from the Kirchen-Berg (Freilingen-Formation) in the Blankenheim syncline has yielded the following taxa: Guerichiphyllum? sp., Enallophrentis n.sp.,

Cyathophyllum (Cyathophyllum) strigosum n.sp., Glossophyllum sp., Heliophyllum (Heliophyllum) halleri Schroeder, Heliophyllum (Moravophyllum) cf. oliveri (Birenheide), Bethanyphyllum ? sp., Thamnophyllum sp. A, Xystriphyllum varians varians (Schlueter), Dohmophyllum helianthoides (Goldfuss), Acanthophyllum heterophyllum (Milne-Edwards & Haime), Acanthophyllum vermiculare (Goldfuss), Stringophyllum cf. acanthicum (Frech), Mesophyllum (Mesophyllum) lissingenense lissingenense (Schlueter), M. (Cystiphyllodes) secundum secundum (Goldfuss), M (Cy.) secundum conistructum (Quenstedt), M. (Cy.) secundum pseudoseptatum (Schulz). The coral-fauna is dominated by typical Upper Eifelian taxa; like the very common Acanthophyllum- and Cystiphyllodes-species. Moreover, a strong "bohemian-american" influence can be recognized. Migrations from the North American faunal region (EAR = Eastern Americas Realm) are visible in the occurrence of Heliophyllum, Bethanyphyllum and a new Enallophrentis-species. Enallophrentis or specimens of the family Siphonophrentidae in general have never been collected in the Rheinisches Schiefergebirge so far. On the other hand, the coral fauna is influenced by eastern european taxa like Heliophyllum (Moravophyllum) and a questionable Guerichiphyllum species. Cyathophyllum (Cyathophyllum) strigosum is described as new. Within the stratigraphical distribution of the Cyathophyllids C. (C.) strigosum intercedes between the Lower Eifelian and Givetian taxa of Cyathophyllum.</ABSTRACT>

6988 <TITLE>Rugose corals from the Upper Koneprusy Limestone (Lower Devonian) in Bohemia.</TITLE>
6989 <SOURCE>Sbor. geol. ved. NR: 35-106.</SOURCE>
6990 <ABSTRACT>Rugose corals from Barrandian "bande f2" are redescribed and discussed. Thirteen species are recognized from the Upper Koneprusy Limestone including the type species of *Chlamydothyllum* Pocta, *Pselophyllum* Pocta and *Pseudochonophyllum* Soshkina. In addition one species is assigned to the Suchomasty Limestone and three to the Acanthopyge Limestone. Type specimens of two "f2" species probably originated in the Silurian and "f2" representatives of two additional species have not been found. Most of the 54 "species " described by Pocta (1902) are placed in synonymy with one of the recognized species. The Upper Koneprusy Limestone primarily consists of

- rubble from the erosion of a reef facies and the rugose fauna is dominated by solitary corals with thick septothecae that show signs of extensive rolling. Corals with thin walls and septa are more common in the Suchomasty and Acanthopyge Limestones.</ABSTRACT>

7001 <TITLE>Espèces du genre Disphyllum (Rugosa) dans le Dévonien moyen et le Frasnien de la Belgique.</TITLE>
7002 <SOURCE>Annales de la Societe geologique de Belgique 93: 159-182.</SOURCE>
7003 <ABSTRACT>15 species of Disphyllum are described from the Middle and Upper Devonian (Frasnian) of Belgium. Of these 4 are new: D. hilli, D. crassiseptatum, D. grabauai and D. gradatum; 3 uncertain. The variations of the external and internal characters of the same species in the different facies are analysed. It has been found that the external and internal characters of the corals such as shape, form of the calyx, septa and dissepiments were strongly influenced by environmental conditions. The biostratigraphical value of the more important species is also briefly given.</ABSTRACT>

7014 <TITLE>Genus Disphyllum de Fromentel (Rugosa) in the Devonian of Poland and its distribution.</TITLE>
7015 <SOURCE>Acta Palaeontologica Polonica 17, 3: 265-335.</SOURCE>
7016 <ABSTRACT>11 species and subspecies of the genus Disphyllum de Fromentel are described from the Devonian of Poland, two of them, D. wirbelauense bonae and D. w. regulare, are new. The geological structure of the Disphyllum-bearing localities from the Holy Cross Mts and Sudetes is discussed. The profiles of deep boreholes from Silesian-Cracow anticlinorium and Pomerania are presented. The coral's blastogeny and intraspecific variability are characterized. The septal index and pattern of internal structure are regarded as taxonomical criteria for specific identifications. It was noted that the microstructure is characterized by coarse monacanth distributed horizontally or in the form of half-fans. Distribution of Disphyllum in Poland and in the world, the moment of its appearance and its biostratigraphical value are discussed.</ABSTRACT>

7080 <SOURCE>Senckenbergiana lethaea 55, 1/5: 251-257.</SOURCE>
7081 <ABSTRACT>A new rugose coral species, Papiliophyllum lissingenense n. sp from the Lissingen exploration trench (Eifel, Gerolstein syncline; 1972), is described and figured. Hitherto species of Papiliophyllum have been known only from the lower Devonian (Onondaga Formation) of Nevada (USA). A new systematic delimitation of the Halliidae Chapman 1893 is proposed. This necessitates the introduction of the new subfamily Siphonophrentinae.</ABSTRACT>

7184 <SOURCE>Senckenbergiana lethaea 58, 1/3: 1-23.</SOURCE>
7185 <ABSTRACT>Two new genera of solitary rugose corals possessing an apex lacking the wall are described from the Lower Emsian / Upper Emsian boundary of the Complejo de La Vid of the localities Adrados and Colle in the Cantabrian Mountains, Spain. The first genus, Gymnaxon n.g., with the species Gymnaxon weyeri n.sp., belongs to the family Cyathaxoniidae Milne-Edwards & Haime 1850, subfamily Petronellinae Birenheide 1965. The second genus, Adradosia n.g., with the species Adradosia barroisi n.sp., belongs to the family Hapsiphyllidae Grabau 1928, subfamily Adradosiinae n.subfam. For the first time new localities of Petronella truncata (Barrois 1882) are recorded. * The absence of the wall on the apex of all these corals is interpreted as resulting from a special mode of reproduction (probably asexual) apparently developed under the ahermatypic quiet water conditions of their environment. * The subfamily Petronellinae of the family Cyathaxoniidae embraces at present 3 genera lacking the wall on the apex: Duncanella Nicholson 1874, Petronella Birenheide 1965 and Gymnaxon n.g. In the subfamily Adradosiina of the family Hapsiphyllidae, the only genus Adradosia n.g. shows this peculiarity. [original abstract]</ABSTRACT>

7379 <SOURCE>Abhandlungen und Berichte für Naturkunde und Vorgeschichte 12, 3: 23-73.</SOURCE>
7380 <ABSTRACT>Rare and poorly known corals of Lower Devonian in Thuringia (saxothuringian zone of mid-European Variscan Mountains) are reviewed in faunal lists, based on critical compilation of published data. There occur two autochthonous communities of hercynian facies type, in the tentaculitid nodular limestone horizon of Pragian or Siegenian age, and in the level C of upper tentaculitid shale horizon of Upper Emsian or Dalejan age (Nowakia richteri zone). A third allochthonous fauna is present in level B of the upper tentaculitid shale horizon (Upper Emsian, Dalejan, Nowakia cancellata zone) and yields a mixture of both rhenish and hercynian facies fossils. * Rugosa of the bathyal upper fauna, found in pelagic shales of the Nowakia richteri zone, belong at the least to twelve species, mostly indeterminable at the moment due to bad preservation (casts). Morphology and taxonomy of the two more abundant species, Paliaxon zimmermanni (Weissermel 1941) and Bojocyclus

- bohemicus Prantl 1939, are revised. The new genus Paliaxon (Metriophyllidae) descends from Neaxon Kullmann 1965, by development of pali similar to Scleractinian ones, which are discussed as to terminology at variance with the primary meaning of the term palus proposed by Edwards (1857) for Caryophyllia cyathus (Ellis & Solander 1786). Bojocyclus Prantl 1939, and its ancestor Rhabdocyclus Lang & Smith 1939, are classified as Tryplasmataceae = Palaeocyclidae within a suborder Pholidophyllina Wedekind 1927, with normal Rugosan septal apparatus, excluded from Cystiphyllina with missing minor septa at counter septum. 7393 <ABSTRACT>Mit Aristophyllum terechovi Bulvanker, Spasskiy & Kravtsov wird die Gattung Aristophyllum Bulvanker, Spasskiy & Kravtsov in der Nord-Eifel nachgewiesen. Es ist das erste Vorkommen dieser bisher nur aus oberdevonischen Ablagerungen der UdSSR und Polens bekannten Gattung in W.-Deutschland. A. terechovi stammt aus den mitteldevonischen Curten-Schichten (Givetium) der Sotener Mulde (Nord-Eifel). Ein kurzer Vergleich mit Breviphyllum stumm wird gezogen und auf die Problematik dieser Gattung hingewiesen. [original abstract] </ABSTRACT>

7404 <TITLE>Seasonal growth bands in Famennian rugose coral *Scruttonia kunthi* and their environmental significance.</TITLE>
7405 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 265, 1-2: 87-92.</SOURCE>
7406 <ABSTRACT>Large colonies of rugose coral *Scruttonia kunthi* occurring in the upper Famennian of Sudetes (southern Poland) reveal distinct growth banding in their skeletons. They were investigated for internal structural characteristics and stable isotopic composition. The skeletal tissue consists of alternating light and dark bands which differ in thickness, density and morphology of structural elements, and in occurrence of corallite contraction and rejuvenescence. Darker parts with densely arranged thick skeletal elements are thin in comparison to lighter parts. In addition, they include frequently offsets and contraction of corallites. A couplet of dense and less dense bands is interpreted to represent most probably an annual cycle. The calculated growth rate for *Scruttonia kunthi* varied from 6 mm/yr to 12 mm/yr. Growth-band formation was influenced environmentally. Oxygen isotopic data provide an evidence that high-density bands were formed in the season of higher environmental stress, with relatively warmer temperatures and higher sedimentation rates. Carbon isotopic signatures are very uniform, and thus enigmatic. They indicate that at least

- growth rate of the skeleton and seawater temperature had no influence on the coral $\delta C13$.</ABSTRACT>

- 7418 <SOURCE>Bulletin de l'Institut royal des sciences naturelles de Belgique, Sciences de la Terre 79: 55-86.</SOURCE>
- 7419 <ABSTRACT>Disphyllum hilli Tsien 1970. D. grabauï Tsien 1970, D. rugosum (Wedekind 1922). D. preslense n.sp. and Peneckiella discreta n.sp. are described in detail and have been mostly collected in beds rich in fasciculate rugose corals, occurring in various areas of Belgium. The material investigated comes mainly from the Palmatolepis transitans and P. punctata conodont Zones, at the transition between the Early and the Middle Frasnian. The rugose corals identified herein allow also interesting regional correlations. Disphyllum hilli, D. grabauï and Macgeea rozkowskæ Coen-Aubert 1982 are abundant at the base of the Moulin Lienaux Formation on the south side of the Dinant Synclinorium and at the base of the Lustin Formation on the north side of the same structural unit. Disphyllum preslense and D. rugosum are widely distributed in the middle part of the Bovesse Formation on the north side of the Namur Synclinorium, in the middle of the reefal limestones from the lower part of the Lustin Formation and in the middle part of the Pont de la Folle Formation which characterizes the northwestern part of the Dinant Synclinorium. Peneckiella discreta serves locally as basement for the small mounds observed at the top of the Moulin Lienaux Formation. Hexagonaria mirabilis Moenke 1954 and Tabulophyllum mcconnelli (Whiteaves 1898) are frequently associated at the base of the overlying Grands Breux Formation, at the top of the Pont de la Folle Formation, at the top of the reefal limestones from the Lustin Formation and at the base of the Huccorgne Formation capping the Bovesse Formation.</ABSTRACT>

- 7497 <ABSTRACT>The rugose coral fauna of the Devonian Burg-Berg section (Upper-Givetian/Frasnian) near Madfeld/east Sauerland is described. The faunal composition is characterized by Upper Givetian taxa and a few long ranging Devonian species. In the lower part of the section (Upper Givetian) the fauna is composed only of solitary species whereas colonial taxa are dominating in the upper part (Frasnian). The following taxa are described: "*Cyathopaedium*" sp., *Spinophyllum spongiosum* (Schlüter 1889), *Macgeea* sp., *Hexagonaria* cf. *hexagona* (Goldfuss 1826), *Grypophyllum postprimum* Birenheide & Lütte 1990, *Dohmophyllum?* sp., *Acanthophyllum* sp. ex gr. *Vermiculare / concavum*, *Sociophyllum* cf. *semiseptatum* (Schlüter 1881), *Mesophyllum* (*Mesophyllum*) *vesiculosum annulifer* (Schlüter 1885). 7536 <ABSTRACT>At the earliest ontogenetical stages, Calceola sandalina has corallum in the form of hemispheric cup provided with peculiar tube-like outgrowths and attachment scar to the substrate; it lacks septa and external growth lines on the wall. At the next stage operculum appears with a pair of submedially situated, relatively large hinge lists. Succesively, large central septum and two lateral septa appear. Attachment scars of desmocytes arranged in double or single rows are present in the calice and inner side of the operculum. Phylogenetic relationships of operculate corals with the Cambrian Cothonion are discussed.</ABSTRACT>

7547 <TITLE>New data on occurrences of the Devonian rugose coral Calceola in Belgium.</TITLE>
7548 <SOURCE>Memoirs of the Association of Australasian Palaeontologists 39: 121-129.ISSN 810-8889</SOURCE>
7549 <ABSTRACT>Opercula and corallites of Calceola sandalina from the late Eifelian and early Givetian (Middle Devonian) Hanonet Formation of Belgium are illustrated. The few previous illustrations of calceoloid corals from the Devonian of Belgium did not include opercula showing the genetically diagnostic morphological features, so for the first time the presence of the genus and species in Belgium is confirmed. One important corallite shows the alar septum and insertion of septa on the external surface of the counter face adjacent to the alar septum. [original abstract]</ABSTRACT>

7560 <TITLE>Middle Devonian Calceola sandalina (Linnaeus, 1771) (Anthozoa, Rugosa) from Moravia (Czech Republic): aspects of functional morphology, gerontic growth patterns, and epibionts.</TITLE>
7561 <SOURCE>Geodiversitas 26, 1: 17-31.</SOURCE>
7562 <ABSTRACT>Middle Devonian (lower Givetian) Calceola sandalina (Linnaeus, 1771) from Celechovice Limestone, Moravia, Czech Republic, displays sharply differing ontogenetic stages. Width of ventral side and size / volume of calice steadily increases in juvenile and adult stages but decreases in some specimens in final stages of life; we consider these reductive late stages to be gerontic characters. " Ventral" side of juvenile specimens is flat and straight while in adults this side becomes convex. We suggest that opening of operculum and shifting part of polyp body mass forward would shift centre of gravity so that calicinal part of adult coral could rock down to sea-bottom. Closing operculum would elevate calice above bottom. Rocking movements could help to free coral from sediment. Operculum positioning could move coral and keep it in optimum feeding position. Single specimens show predation injury: almost half of the "ventral " side is missing between counter septum and corallite angle but has healed within calice. [original abstract]</ABSTRACT>

7587 <SOURCE>Freiberger Forschung. C 504: 7-31.</SOURCE>
7588 <ABSTRACT>Morphology and systematics of the genera Combophyllum M. Edw. & H. 1850, and Parmasessor Ludwig 1869, and of the polyphyletic family Hadrophyllidae Nicholson 1889, are revised. Combophyllidae (Devonian), Cumminsiinae (Carboniferous), and Gymnophyllidae (Upper Carboniferous) are new family rank taxa. Combophyllum sp. aff. leonense

- M. Edw. & Haime 1851, and Parmasessor cf. ovatus Ludwig 1869, have been determined from basal Eifelian beds in the western Thuringian Mountains. A redefinition based on typical examples is given for the Rugosan and Scleractinian morphological terms epitheca and archaeotheca. The presence of true eutheca and epitheca is recorded from some few Rugose corals. The typical wall structure of nearly all solitary Rugosa is an archaeotheca.</ABSTRACT>

7599 <TITLE>'Cystimorphe" rugose Korallen aus dem Devon des Kantabrischen Gebirges, N-Spanien.</TITLE>
- 7600 <SOURCE>Senckenbergiana Lethaea 62, 2/6: 251-273.</SOURCE>
7601 <ABSTRACT>Cystimorph rugose corals of Upper Emsian - ?Lower Eifelian age (La Vid Fm., Raneces Fm., Sta. Lucia Fm., Moniello Fm.) and of Givetian age (Lower Portilla Fm., Lower Candas Fm.) from the Cantabrian Mountains s.l. are described for the first time. They belong to the genera and subgenera Edaphophyllum Simpson 1900, Mesophyllum (Mesophyllum) Schlueter 1889, Mesophyllum (Cystiphyllodes) Chapman 1893 and Cayugaea Lambe 1901. The following species and subspecies are new: Mesophyllum (Cystiphyllodes) monielloense n.sp., M. (C.) secundum ascendens n.ssp., M. (C.) macrocystis leonense n.ssp. and Cayugaea hispanica n.sp. Our material of these new taxa is with one exception probably exclusively of Upper Emsian age. It shows closer relations to N. American cystimorphs than to contemporary corals of the Rhenish Mountains. On the other hand the Givetian cystimorphs from the Lower Portilla and Lower Candas Formations can easily be identified with already described taxa from the Eifel synclines. Of the species of the subgenus Mesophyllum (Mesophyllum) Schlueter 1889 only one - of Givetian age - has been recorded from the Devonian of N. Spain, in spite of the worldwide distribution of some of them. As they are normally very abundant, mainly in Eifelian beds, it is probable that in the listed N. Spanish localities sediments of Eifelian age are not at all, or only very poorly, represented.</ABSTRACT>

7614 <ABSTRACT>Temnophyllum majus Walther, 1929, T. imperfectum n.sp., Spinophyllum spongiosum (Schlüter, 1889) and S. blacourti (Rohart, 1988) are described in detail and come mainly from the lower part of the Givetian Mont d'Hauers Formation, on the south side of the Dinant synclinorium. The type specimens of S. spongiosum, Temnophyllum majus, T. latum Walther, 1929 and T. clavatum Walther, 1929 as well as the holotype of Spinophyllum altevogti (Oliver & Sorauf, 1988) are refigured herein. As a whole, the fauna from the Mont d'Hauers

- Formation, which belongs to the Lower Polygnathus varcus Zone, is widely distributed in various areas of Europe and Asia and shows strong affinities with the Givetian rugose corals from Germany and the Boulonnais in France.</ABSTRACT>

7690 <TITLE>Late Frasnian phillipsastreid biostromes in Belgium.</TITLE>
7691 <SOURCE>Geological Society of London, Special Publications 275: 143-161.</SOURCE>
7692 <ABSTRACT>In the Belgian Namur-Dinant Basin the boundary between the Lustin Formation and the Aisemont Formation (in the Lower rhenana conodont Biozone) corresponds to a fall followed by a rise in sea level, leading to the first recorded late Frasnian coral crisis. The Aisemont Formation records a transgressive-regressive cycle. Prior to the crisis most of the colonial rugose corals were members of the Family Disphyllidae, but these were largely replaced by corals belonging to the Phillipsastraeidae. Among these Frechastraea colonized all environments of the basin and was the main constructor of a biostromal reef in its northern-most proximal area, in the fair-weather wave zone. Corals did not encrust each other and therefore were not firmly attached, but they hug tightly the substrate (a dead coral colony) and rest closely on it to resist to the turbulence of waves. During the silurian and Devonian, up until the late Frasnian crisis, shallow-water reefs in turbulent water were usually built by encrusting stromatoporoids, whereas rugose corals were restricted to waters of lower energy. Indeed, they were unable to encrust substrates, unlike stromatoporoids and post-Palaeozoic scleractinians, and to live in turbulent habitats. In Belgium argillaceous sedimentation prevented the

development of stromatoporoids and provided an opportunity for the corals to colonize empty niches and to construct biostromes in relatively high-energy environments. At the same time Alveolites and stromatoporoids were dominant in a mid-proximal environment below the fair-weather wave base, but within the storm wave zone, where they also constructed biostromes. 7703 <TITLE>Koloniebildende Phillipsastreidae und Hexagonariinae aus dem Givetium des Messinghaeuser Sattels und vom Suedrand des Briloner Massenkalkes (nordostliches Sauerland).</TITLE>

7704 <SOURCE>Geol. Palaeont. westf. 26: 7-45.</SOURCE>

7705 <ABSTRACT>The majority of the compound rugose corals described in this paper derives from debris flow sediments of the Messinghausen Anticline, which is situated in the southeast of the Devonian Brilon Massive Limestone Complex. The succession of Middle and Upper Devonian conodont zones was pointed out for this area by Stritzke (1980, 1986, 1989 and 1990). Rugosa taken from sections can be dated by this means. *Thamnophyllum simplex* n.sp. is an abundant element within Middle Givetian initial faunas (Middle varcus Zone), settling on volcanic sea-mountains and ridges. The occurrence of *Phillipsastrea*, represented by the type species *P. hennahi* (Lonsdale 1840), is confirmed for the Upper Givetian (Upper varcus Zone up to the lower part of the Lowermost asymmetricus Zone). This contradicts to the general opinion, that the first appearance of *Phillipsastrea* marks out the beginning of the Upper Devonian in Central Europe. The use of this genus as an index fossil resulted in wrong datings of strata, which led to misinterpretations of sedimentary and palaeogeographical developments even in the latest publications concerning regional geological circumstances. Samples of the very similar *Scruttonia sanctacrucensis* (Rozkowska 1953) also have been taken from Upper Givetian strata. In addition *Kuangxiastrea julli* Pedder 1986 has been found in Givetian deposits (lower part of the Lowermost asymmetricus Zone) as well. For this reason the species neither can be regarded as a Frasnian index fossil in Europe, what had been presumed in literature. The new data do not only take effect on the interpretation of reef development within the northeastern Rhenish Slate Mountains. Former conceptions concerning rugosan stratigraphy of the Middle-Upper Devonian transition and derived palaeobiogeographical models for the Devonian of Europe will have to be revised.</ABSTRACT>

- 7731 <ABSTRACT>Two new genera of the suborder Plerophyllina Soshkina 1960, hitherto unknown in the German Middle Devonian, are described and figured. The first one, *Gerolasma* n.g. (type species *G. geesensis* n.sp.) is phaceloid with a *Tetralasma* trend and comes from the Upper Eifelian of the Gerolstein Syncline. The second genus, *Pentaxon* n.g. (type species *P. struvei* n.sp.), solitary and showing a complex axial structure, has been collected in the Lower Givetian of the Hillesheim Syncline. The new genera represent different families, *Polycoeliidae* de Fromentel 1861 and *Pentaphyllidae* Schindewolf 1942 respectively. Stratigraphy and facies environment of the cited localities are discussed. [original summary]</ABSTRACT>

- 7770 <ABSTRACT>The Siphonophrentidae Merriam 1974 is a family of rugose corals endemic to the Eastern Americas Realm (EAR) during the Lower Devonian. Beginning in the Middle Devonian the siphonophrentids migrated eastward into the Old World Realm (OWR). This migration was controlled by sea level fluctuations (phases of transgressive events). Thus, siphonophrentids are useful for paleogeographic reconstructions and in identification of migration routes during the Devonian. Taxa known from western Europe are reviewed relative to their taxonomic status and stratigraphic and geographic distribution. Some records from Germany and Spain are discussed in detail and figured for the first time.</ABSTRACT>

- 7783 <ABSTRACT>Breviphrentis martinae n.sp. and Rhytidolasma dahlemense (Haller 1936) have been collected near the base of the Hanonet Formation at Resteigne; this level still belongs to the Eifelien and the discovery of these two taxa implies a North American influence which also characterizes other parts of western and Central Europe. Keriophyllum maillieuxi (Tsien 1969) has been observed at the top of the Hanonet Formation and at the base of the overlying Trois-Fontaines Formation in Resteigne, Nismes and Glageon; these layers belong to the base of the Givetian. From a taxonomic point of view, Keriophyllum yakowlewi Haller 1936 is placed in synonymy with Rhytidolasma dahlemense whereas the definitions of the genus Keriophyllum wedekind 1923 and of the species K. maillieuxi are emended. Several type specimens of the genera Rhytidolasma Pedder 1989 and Keriophyllum wedekind 1923 are also refigured.</ABSTRACT>

7795 <SOURCE>Coral Research Bulletin 7: 229-240. [Dieter weyer's 65th birthday commemorative volume; S. Schröder, H. Löser & K. Oekentorp (eds)]</SOURCE>
7796 <ABSTRACT>Four species of the family Siphonophrentidae Merriam 1974 are described from the Holy Cross Mts, Poland. The two species, Enallophrentis corniformis (Gürich 1896), and Enallophrentis polonica (Sobolev 1904) are revised, although their type material is missing; the two species described as new are Siphonophrentis laskowae sp.n. and ?Siphonophrentis georgii sp.n. The corals studied were possibly of the Eastern Americas origin, introduced into the Old world biogeographic Realm. During the Givetian they inhabited the fore-reef setting of the Holy Cross area. Both Eifelian and Frasnian records of Siphonophrentidae in Poland are taxonomically dubious. [original abstract]</ABSTRACT>

7833 <TITLE>Korallen aus dem höheren Eifelium und unteren Givetium (Devon) des nordwest-lichen Sauerlandes (Rheinisches Schiefergebirge). Teil II:

- Rugose Korallen, Chaetetiden und spezielle Themen.</TITLE>
- 7834 <SOURCE>Palaeontographica A228, 1-3: 1-103.</SOURCE>
- 7835 <ABSTRACT>From the Middle Eifelian to the Lower Givetian strata of the northwestern Sauerland (map sheet 4612 Iserlohn, 4711 Luedenscheid and 4713 Plettenberg) 19 rugose corals and 2 chaetetid species are described. The material has been collected mostly in the coral limestone of the Gruenewiese-Member (uppermost Eifelian) of the Ihmert-Formation and the Bredenbruch-Member (lower Lower Givetian) of the Unterhonsel-Formation. The compound coral *Smithiophyllum kloeckneri* n.sp. is new. *Glossophyllum occidentale* (Hill & Jell 1971), *Glossophyllum* ? aff. *excavatum* (Hill 1942), and *Sociophyllum longiseptatum* Bulvanker 1958 have been found for the first time in Central or western Europe. 4 other *Rugosa* species and 1 *Chaetetida* species are described from the Eastern Rhenish Massif for the first time as well. The skeletons of reef-builders are frequently affected by diagenetic processes - most important are alterations of the microstructure and thickenings of skeletal elements. Some reef-builders contain habitats of "worm"-commensals and some other borings. The coral limestone of the Gruenewiese-Member and the Bredenbruch-Member are mostly biostromes, built in a normal marine environment of the euphotic zone between storm wave base and normal wave base. Palaeobiographical investigations show, that the "Rhenohercynian Basin" was only a marginal sea, into that from the east faunas of the asiatic part of the "Old world Realm" immigrate.</ABSTRACT>

- 7846 <TITLE>Famennian Rugosa and Heterocorallia from southern Poland.</TITLE>
- 7847 <SOURCE>Palaeontologia Polonica 61: 3-88.</SOURCE>
- 7848 <ABSTRACT>Famennian corals (*Rugosa* and *Heterocorallia*) occur in three areas of southern Poland: the Holy Cross Mountains and the Kraków area situated along the south-western margin of the East European Platform, and the Sudetes located within the Variscan orogenic belt. In the deep-water Famennian environments of the Holy Cross Mountains (Kowala) the first corals appeared after the Frasnian-Famennian crisis in the P. marginifera to P. trachytera zones. They are represented by monospecific assemblages of *Circellia concava*, a species able to live on a soft muddy and dysaerobic bottom. On even more organic-rich sediment heterocorals *Oligophylloides* flourished; they are suggested to feed on suspended or dissolved organic matter. When the environment became more aerated in the P. expansa and S. praesulcata zones more diverse coral assemblages appeared, including large dissepimented solitary rugosans. In the extremely shallow-water limestone facies ("Stromatoporoid Rocks") of the Kraków region, two species of the colonial rugose coral *Pseudoendophyllum* and several solitary corals are represented. The shallow shelf carbonate facies of the Sudetes (Main Limestone) starts with assemblages dominated by three species of massive colonial *Scruttonia* followed by assemblages with a few species of solitary dissepimented corals. The colonial corals disappeared with the incursion of deeper-water cephalopod *Wocklumeria* limestone facies and only solitary non-dissepimented corals and heterocorals remained. The colonial *Rugosa* of Famennian age are almost unknown in other regions of the world. Their abundance in the Sudetes and the Kraków region suggests that these areas represented a refuge for corals during the high sea stand of the latest Devonian. Several Famennian corals

- reveal characters typical for those of either the Frasnian or Viséan. These characters are more likely to develop convergently than represent continuity within lineages. *Pseudoendophyllum raclaviense* sp. n. *Scruttonia sudetica* sp. n., *S. fedorowskii* sp. n., and *Oligophylloides weyeri* sp. n. are proposed. </ABSTRACT>

- 7860 <SOURCE>Trabajos de Geologia, Universidad de Oviedo 15 : 203-209.</SOURCE>
- 7861 <ABSTRACT>In this paper a Rugose coral-Stromatoporoid association is studied, which is present in several levels of an organic buildup occurring within the middle part of the Moniello Formation (Emsian-Eifelian) in Arnao (Asturia, Cantabrian Mountains, NW Spain). The features of this fossil association are analysed in detail in order to establish the possible relationship between its components. A commensal relationship with clear benefit for the Rugose coral is suggested. (Original summary)</ABSTRACT>

- 7886 <SOURCE>Fortschr. Geol. Rheinld. u. Westf. 37: 161-213.</SOURCE>
7887 <ABSTRACT>Rock samples of the Viersen 1001 borehole from depths between 1,012.85 and 1,496.80 m contain specimens of seven rugose and nine tabulate coral species which are described and figured herein; one of the tabulates, *Remesia obscura* n.sp., is new. The species composition of the coral fauna is comparable to that of the Aachen Massenkalk limestone and the Ardennes. The investigated material comprises a time interval between Early (?) Givetian and Upper Frasnian. By far the greatest part of this interval is represented by the *Polygnathus varcus* conodont zone. Furthermore, the coral record also allows a discrimination of a Middle Givetian (here: Rodert to Kerpen Formation) and part of the Fromelennian. In thin sections, the Fromelennian and Frasnian specimens show evidence of dispersal caused by rough weather periods within a normally quiet, shallow-water environment with a relatively high content of clay components. On the other hand all the Middle Givetian and possible Lower Givetian specimens come from the basal phyllite conglomerate of the examined section.</ABSTRACT>

- 7976 <TITLE>Late Devonian stromatoporoid from the Sudetes Mountains (Poland) and endemicity of the Upper Famennian to Uppermost Famennian (= "Strunian") stromatoporoid fauna in western Europe.</TITLE>
- 7977 <SOURCE>Senckenbergiana lethaea 79, 1: 51-61. [in memoriam Dr. Wolfgang Struve]</SOURCE>
- 7978 <ABSTRACT>A single large stromatoporoid specimen collected by one of us (D.W.) from the so-called "Main Limestone" at Dzikowiec (=Ebersdorf) in the Sudetes Mountains of Lower Silesia, Poland, is here assigned to Trupetostroma Parks, 1936. It is typical of the Upper Famennian to Uppermost Famennian (= "Strunian") stromatoporoid assemblage No. 3 defined by Stearn (1987) and Stearn, Halim-Dihardja & Nishida (1987). This assemblage, confined to western Europe and Kazakhstan, is dominated by clathrodictyids but without labechiids. Other genera present with Trupetostroma in this assemblage include Amphipora, Anostylostroma, Atelodictyon, Clathrocoilon, Clathrodictyon, Clathrostroma, Gerronostroma, Petridiostroma, and Stromatopora. All these genera were widespread globally through the Middle and Upper Devonian (Givetian-Frasnian) but in the Upper Famennian to Uppermost Famennian (= "Strunian") deposits of western Europe they appear as "Lazarus taxa" - a consequence of the Frasnian/Famennian boundary Kellwasser event which terminated reefal environments world- wide. Viewed at the generic level, the western European Upper Famennian to Uppermost Famennian stromatoporoid fauna is essentially ubiquitous, but at the species level endemism is pronounced. This may have resulted from reactivation of distinct biotopes when conditions became conducive, locally, to renewed reef development. The endemicity is analysed using the Jaccard coefficient.</ABSTRACT>

- 7990 <SOURCE>Revista Española de Paleontología no. extra homenaje al Prof. J. Truyols: 121-128.</SOURCE>
- 7991 <ABSTRACT>The Santa Lucía Formation, from the Devonian (late Emsian-early Eifelian) in the Canatabrian Mountains (NW Spain) yields an abundant and diversified stromatoporoid fauna; one of the most common taxa is the genus Actinostroma Nicholson. In this work the specimens studied are assigned to four species of this genus. A.

- stellulatum Nicholson, A. verrucosum (Goldfuss), A. geminatum Lecompte and A. cf. conglomeratum Lecompte. The last two species have already been reported from the Cantabrian Mountains, but they are figured for the first time. A. verrucosum, A. geminatum, and A. cf. conglomeratum corresponding to the Actinostroma verrucosum group of Lecompte, have been a matter of discussion and even, assigned to the genus Nexililamina Mallett. The above mentioned species show a typical hexactinellid network which allows us to keep them in the genus Actinostroma s.l.

8004 <ABSTRACT>within the Pragian (Lower Devonian) reefs are extremely rare world-wide. A remarkable exception is the occurrence of a large reef complex in the Pragian near the Bohemian village of Koneprusy (ca. 30 km SW of Prague). Two large quarries expose the Koneprusy limestone (of kindlei conodont zone) in which stromatoporoids are rare. In addition to the taxa found by Pocta (1894) and May (1999) the following stromatoporoids were found and are described in detail: Actinostroma clathratum, A. sertiforme, Plectostroma yunnanense, P. crassum, Stromatoporella sp., Hermatostroma holmesae, and Salairella insignis. Common commensal worms and growth pits induced by non-preserved organisms are also described.</ABSTRACT>

- 8030 <ABSTRACT>Cette etude complete une precedente monographie (Mistiaen 1980) consacree aux Stromatopores du Givetien de Ferques. 60 taxons sont reconnus, leur repartition est precisee. Les 18 taxons suivants sont decrits: Actinostroma cf. filitextum Nicholson 1886, Actinostroma ? cf. sertiforme Lecompte 1951, Pseudostictostroma sp., Clathrocoilona inconstans Stearn 1962, C. spissa (Lecompte 1951), Stictostroma saginatum (Lecompte 1951), S. ciuriosa (Bargatzky 1881), Gerronostroma lemniscum (Lecompte 1951), Syringostromella cooperi (Lecompte 1952), Habrostroma percanaliculata (Lecompte 1951), Stachyodes australe (Wray 1967), Idiostroma roemeri irregularis (Heinrich 1914), Amphipora pervesiculata Lecompte 1952, A. cf. laxeperforata Lecompte 1952, A. sp., Euryamphipora sp. Plusieurs biozones a Stromatopores sont proposees, 3 pour le Givetien et 2 pour le Frasnien; elles sont caracterisees par des associations, l'extension ou l'acme de certaines especes. Deux ensembles fauniques tres distincts sont mis en evidence: un ensemble givetien, caracterise par une grande diversite (polystoeie) au niveau generique (19 genres) et specifique (41 especes) et un ensemble frasnien a faible diversite (oligostoeie) generique (8 genres) et specifique (15 especes), pour des nombres comparables de specimens recoltes. Cette observation peut etre correele au mode de construction recifale: de type bioherme, a nombreuses possibilites de niches ecologiques au Givetien - biostromes aux conditions ecologiques plus homogenes au Frasnien.</ABSTRACT>

- 8042 <SOURCE>Aachen Technische Hochschule, Dissertationen; 178 pp., 49 figs., 13 tabs.</SOURCE>
- 8043 <ABSTRACT>[unpublished ?] The worldwide Devonian reef growth was terminated in the large areas during the triangularis- and gigas-Zone (do I γ/δ). To explain this phenomenon six profiles with the transition from reef- to non-reef facies ranging from Namur (Belgium) to Wuppertal (W.-Germany) were investigated microscopically and geochemically. * It turned out that the periodically increased production and sedimentation of clayey and mainly organic material directly controlled the Upper Devonian reef growth and finally caused its termination. * Increased plate tectonical shifting of the land areas during the Upper Devonian finally triggered off the following chain of events: increasing rates of periodical rainfall - intensified spreading of land plants - increased chemical weathering - periodically increased transport of nutrients and clastic material into the reef habitat - increased production and sedimentation of phytoplankton - termination of reef growth - final euxinic sedimentation (lower Kellwasser limestone, do I δ).</ABSTRACT>

8054 <TITLE>Lower Devonian stromatoporoids of the Sierra Morena (Southern Spain) and their palaeogeographic affinities.</TITLE>
8055 <SOURCE>Österreichische Akademie der Wissenschaften, Schriftenreihe der Erdwissenschaftlichen Kommissionen 17: 139-151. ISBN 978-3-7001-3826-6</SOURCE>
8056 <ABSTRACT>For the first time the stromatoporoid fauna from two locations in the Penón Cortado Limestone (Upper Emsian) from the Sierra Morena (Southern Spain) has been examined in detail. The fauna contains 8 stromatoporoid species. One of them, a new species, is described as Pseudotrurpetostroma anacontentoae n.sp. The absence of stromatoporoids with branched coenostea and the scarcity of stromatoporoids with thin-layered encrusting growth form probably served as an obstacle to reef construction. The fauna of the Sierra Morena is unrelated to that of the Eastern Americas Realm. However, it is closely related to Emsian faunas of Australia and Canada. There is no evidence to suggest that Southern Spain was a refuge for Eastern Americas stromatoporoids.</ABSTRACT>

8067 <TITLE>Stromatoporen aus dem Givet und Frasn des Bergischen Landes.</TITLE>
8068 <SOURCE>Geologisches Institut der Universitaet zu Köln, Sonderveröffentlichungen 106: 182 pp.</SOURCE>
8069 <ABSTRACT>In the lower Givetian reef builders used littoral sediments of sand, silt and clay as a foundation for thin biostromes which could exist in spite of repeated sedimentation. In consequence of constant favourable conditions a reef with typical reef facies developed in the upper Givetian. In the Frasnian these bioherms were drowned as sea level rose. The reef evolution of the Bergisch Gladbacher-Paflrather Mulde is analysed by the description of the stromatoporoids which represent an important group of Devonian reefbuilders. The descriptions include 56 species, 11 taxa comparable with described species (cf.), and 2 taxa identified only generically (sp.). The shapes of the skeletons are also described. To better describe and define the species the scanning electron microscope and image processing supplemented the usual skeletal measurements. Except for the dendroid species, all stromatoporoids changed their growth structure according to the predominate environment. Therefore layered flat species appear mostly at the base of the reef and knobby, globular or massive stromatoporoids existed mostly in high energy reef zones. The dendroid species were often found in the lower energy reef zones with high sedimentation rates. The stratigraphic distributions of several species from the area were compared with those from other areas. The distribution of the Middle Devonian Clathrocoilonabeona and Anostylostroma columnare and the Upper Devonian Trurpetostroma cimanense are notable. 8081 <SOURCE>Vestn. Ustred. ustavu geol. 66, 5: 275-285.</SOURCE>
8082 <ABSTRACT>Four lithofacies are apparent in the studied sections: fore-reef facies with possible contourite, resulting from presumed reef drowning or reef backstep; poorly developed buildup facies with boundstones of encrusting stromatoporoids; Amphipora-rich back-reef facies, mainly with floatstones; and anoxic lagoon facies of dark, laminated mudstone without fossils and bioturbations. The backstepping of the reef is interpreted here as a result of eustatic and subsidence changes which finally prevented the development of reef facies.</ABSTRACT>

8094 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: 359-364.</SOURCE>
8095 <ABSTRACT>During the Strunian (latest Devonian), a transgression initiated shallow-water carbonate sedimentation on the western European Condroz shelf along the southeastern shore of the Old Red Continent. The succession contains the youngest Stromatoporoid biostromes of the world. Facies studies from the Aachen region demonstrate a mixed carbonate - siliciclastic ramp with confined fossil assemblages. Biostromes are pioneer structures with extremely low diversity and integration. The binder guild, only formed by stromatoporoids, is of overwhelming importance. Biostromes are neither linked distinctly to Devonian nor Carboniferous buildups. Expansion and extinction is mostly controlled by sealevel changes.</ABSTRACT>

8106 <TITLE>Genus Stromatoporella Nicholson 1886 from the Cantabrian Mountains (Santa Lucia Formation, Lower-Middle Devonian, NW Spain).</TITLE>
8107 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 343-353.</SOURCE>
8108 <ABSTRACT>The genus Stromatoporella Nicholson 1886 is very abundant in

- the Santa Lucia Formation (Upper Emsian-Lower Eifelian), in the Cantabrian Mountains, NW Spain. The present study is based on more than one hundred specimens collected from different sections, all of them located on the southern slope of the Cantabrian Mountains. The studied specimens show large variations in the typical characters of the genus, especially the shape and abundance of ring-pillars. Five species have been recognized in open nomenclature; a comparative study was made, mainly based on the different features of the ring-pillars, in order to verify if they allow characterization of the different species. In general, the morphological features of ring-pillars such as shape, relative number of shorter, higher ring-pillars or as high as one interlaminar space, presence of dissepiments and wall thickness are suitable criteria to differentiate the species involved in this study. Some other features, such as density are more variable and, thus, are of less systematic value.</ABSTRACT>

8120 <SOURCE>Memoires Institut Geologique de l'Universite Catholique de Louvain 35: 191-195.</SOURCE>
8121 <ABSTRACT>The genus Keega Wray 1967, was created for a Frasnian species and originally interpreted as a coralline alga. In 1974 Riding demonstrated it was not an alga but a laminar stromatoporoid belonging to the genus Stachyodes. S. australis is here recorded for the first time in the Frasnian of Belgium. Some paleoecological observations lead us to think that S. australe was growing in a very quiet environment and was not encrusting but just like a loose sheet lying on the bottom.</ABSTRACT>

8160 <ABSTRACT>Stromatoporoids have been measured in three Upper Devonian
localities: Karwow, Kadzielnia and Sitkowka quarries. Quantitative
analysis in the measurements demonstrated several differences that have
been interpreted in terms of ecological variations between localities.
Rate of deposition is proposed to be of special importance in
controlling stromatoporoid morphology. Deposits exposed in Kadzielnia
and Karwow quarries represent an environment with periodically
accelerating deposition and water turbidity, where low domical
individuals with a ragged surface and non-enveloping arrangement of
latilaminae constitute the most numerous group of stromatoporoids. The
deposits outcropping in Sitkowka-Kowala quarry, formed in a calm
setting with low deposition rate, are characterized by the following
stromatoporoid features: usually extended domical or bulbous shape,
smooth surface and an enveloping arrangement of latilaminae. The
similarity of stromatoporoid assemblages from Karwow and Kadzielnia
confirmed that dolomite exposed in the Karwow quarry represents
Kadzielnia-type reef-mound deposits.</ABSTRACT>

8277 <ABSTRACT>A section in Devon shows a transition from laminar forms, through domal forms to bulbous forms at the top. The changes in the growth forms are documented through use of the triangular plot suggested by Kershaw and Riding (1978). The raggedness index is also measured. The changes in form suggest a shallowing upward sequence.</ABSTRACT>

8289 <SOURCE>Bulletin du Museum national d'histoire naturelle Paris, 4e ser. 2 (C), 3: 167-257.</SOURCE>
8290 <ABSTRACT>Givetian fauna of stromatoporoids of Ferques (Boulonnais), up to now completely unknown, has, however, revealed itself very varied. Thirteen levels, more or less rich in stromatoporoids, have been located. They all belong to the 'Membre du Griset'. Among more than 40 taxons present, 36 are described, belonging to 15 different genera. Their stratigraphic distribution is given and discussed. Comparisons, especially with the 'Ardenne', are worked out. [original summary; stratigraphy of the section and the occurrence of the stromatoporoids in each bed is documented; thirty-six species belonging to 15 different genera are described and illustrated: Actinostroma (9), Atelodictyon (1), Clathrodiction (1), Anostylostroma (1), Trupetostroma (2), Pseudostylodiction (1) Clathrocoilona (3), Stromatoporella (1), Synthetostroma (1), Hermatostroma (6), Stromatopora (6), Ferestromatopora (1), Parallelopore (1), Stachyodes (1), and Dendrostroma (1)]</ABSTRACT>

8327 <TITLE>Stromatoporoid palaeoecology of the Frasnian (Upper Devonian) of southern Belgium.</TITLE>
8328 <SOURCE>Third International Palaeontological Congress Programme and Abstracts, p. 135.</SOURCE>
8329 <ABSTRACT>Stromatoporoid faunas from the Frasnian of southern Belgium are abundant in the carbonate platform and mound environments present in this area. Stromatoporoids dominate the large skeletal organisms, with their principal occurrence in biostromes and mound deposits. Stromatoporoid genera include Actinostroma, Amphipora, Euryamphipora, Atelodictyon, Clathrocoilonia, Idiostroma, Salairella, Stachyodes, Stictostroma, Stromatopora and Trupetostroma. Comparable facies were observed in the carbonate platform and in the mound, so it appears that even if the mound and platform were independent, similar stromatoporoids occur in similar facies indicating a strong palaeo-environmental control. From the more distal to the more proximal, facies are: (1) outer platform or off-mound (shales, crinoidal packstones); (2) outer intermediate platform or deep mound (muddy facies with crinoids and reef-builders); (3) inner intermediate platform or shallow mound (muddy facies with algae) and (4) restricted platform or mound (laminites, mudstones, paleosols). Low profile stromatoporoids (dominated by Stictostroma and Salairella) are often observed at the beginning of sequences, as stabilizers and in facies 1 and 2 (so they likely led to expansion of the carbonate factory). High domical stromatoporoids (dominated by Actinostroma, Atelodictyon and Trupetostroma) occur in facies 3 and 4, in association with branching stromatoporoids. Stromatoporoid growth forms seem to be related mostly to environmental parameters but there is also some taxonomic control.</ABSTRACT>

8340 <TITLE>Growth forms and distribution patterns of stromatoporoids exposed on Devonian palaeobottom surfaces; Holy Cross Mountains,

- central Poland.</TITLE>
- 8341 <SOURCE>Acta Geologica Polonica 58, 3: 303-320.
http://www.geo.uw.edu.pl/agp/</SOURCE>
- 8342 <ABSTRACT>Well preserved palaeobottom surfaces with stromatoporoids are exposed in two Devonian localities in the Holy Cross Mountains in central Poland: Skaly and Bolechowice-Panek quarries. The stromatoporoids were subjected to morphometric analysis and distribution studies. Stromatoporoids were studied hitherto only in vertical cross sections; the study of three-dimensional stromatoporoid domes has created a need to introduce a new set of parameters describing their shapes, which includes: horizontal length and width, vertical height, elongation ratio and elongation azimuth. In order to make the measurements made by various methods comparable, and thus to allow comparable interpretations, recalculation formulas have been presented. Comparison of the results obtained by the two methods indicates that the measurements made in vertical cross sections substantially bias the dimensions and shapes of the stromatoporoids, which may influence stromatoporoid-based palaeoenvironmental reconstructions. The results of the measurements were interpreted in terms of palaeoenvironmental conditions. In Bolechowice-Panek the stromatoporoids lived in a quiet shallow water setting with a low and stable sedimentation rate. In Skaly the stromatoporoids grew in a shallow subtidal setting and located themselves on parallel ripples, most probably to escape being buried by deposits accumulating in inter-ripple depressions.</ABSTRACT>

- 8353 <TITLE>Stromatoporoid growth orientation as a tool in palaeotopography: a case study from the Kadzielnia Quarry, Holy Cross Mountains, central Poland.</TITLE>
- 8354 <SOURCE>Acta Geologica Polonica 59, 3: 319-340.
http://www.geo.uw.edu.pl/agp/</SOURCE>
- 8355 <ABSTRACT>Growth orientation of stromatoporoids has allowed reconstruction of the palaeotopographic position of a large Frasnian organic buildup exposed in the Kadzielnia Quarry in the Holy Cross Mountains, central Poland. Two main, mature stage, stromatoporoid growth modes have been discerned: erect and semi-buried. The growth orientations of the stromatoporoids were studied in 17 sections that expose four different facies in the quarry. The inclinations of the basal surfaces of specimens and direction of the growth axes were measured and compared in terms of different growth modes, facies and positions in the organic buildup. The results support the earlier opinions that the inclined contact between the Kadzielnia stromatoporoid-coral limestones and the detrital limestones is depositional and represents an inclined depositional surface, and that the Kadzielnia buildup developed in a calm water setting below the storm wave base on a slope or at its foot. General conclusions emerging from the studies are: 1) stromatoporoid growth directions hold a key to reconstructing ancient topography; 2) erect stromatoporoids that grew on inclined surfaces changed the growth axes to the vertical direction during their growth; and 3) stromatoporoid growth directions and particularly the changing mode of growth of erect forms support the view that Palaeozoic stromatoporoids acted photosensitively.</ABSTRACT>

8366 <TITLE>Late Famennian stromatoporoids from Debnik Anticline, southern Poland.</TITLE>
8367 <SOURCE>Acta Palaeontologica Polonica 54, 2: 337-350.</SOURCE>
8368 <ABSTRACT>Famennian Stromatoporoidea from the Quasiendothyra communis Foraminiferal Zone and slightly younger strata from the Debnik anticline, southern Poland, form a succession of three consecutive assemblages. Assemblages 1 and 3 consist of representatives of the order Clathrodictyida, while assemblage 2 is dominated by the order Labechiida. The clathrodictyids are represented by the genus Gerronostroma, and labechiids are represented by the genus Stylostroma. Species assigned here to the genus Gerronostroma show a network of amalgamated pillars in the central part of the columns, a feature regarded by previous authors as typical of the genus Clavidictyon. Two new species, Stylostroma multiformis sp.nov. and Gerronostroma raclaviense sp.nov., are described. Stromatoporoids from southern Poland differ from the Famennian fauna of western Europe, showing affinity to eastern European and Siberian Stromatoporoidea.</ABSTRACT>

- 8394 <ABSTRACT>This section of the Polish Atlas of Index and Characteristic Fossils is a condensation of the 1971 monograph of Kazmierczak on Stromatoporoids from the Holy Cross Mountains (Palaeontologia Polonica 26). Thirty-nine species are described briefly and illustrated with rearranged photomicrographs from the 1971 publication. Generic discussions are not included. Ten species have been dropped from the faunal list. In an introduction of two and a half pages the hypothesis that the stromatoporoids should be placed in the Cyanophyta is adopted. [comment by C.W. Stearn; see also bibliographic note in Fossil Cnidaria & Porifera 32, 2, p. 56]</ABSTRACT>

- 8406 <SOURCE>Acta Geologica Polonica 53, 1: 19-27.</SOURCE>
- 8407 <ABSTRACT>Stromatoporoid skeletons from polished slabs of stromatoporoid- and coral-bearing limestones of the Upper Devonian Kowala Formation from the Holy Cross Mountains in central Poland have been measured using a classic parameterization method, introduced by Kershaw & Riding (1978) and improved by Kershaw (1984, 1998). The stromatoporoid shape appeared to be strongly dependent on its size - the V/B ratio decreases along with increasing B. The relation can be well matched by a curve described by a formula: $f(x) = 5.7103x^{0.81633}$. The size of the measured specimens must therefore be taken into account in those studies of the stromatoporoid morphology, where it is concerned a palaeoenvironmental indicator. The stromatoporoids adopted several types of initial surfaces, corresponding to various growth strategies in the first phase of their growth in response to various environmental conditions, such as substrate consistency and sedimentation rate. Latilaminae arrangement well records the stromatoporoid growth history and therefore its studies are crucial in environmental interpretations, as the conclusions inferred from the shape alone might be very misleading. - 8420 <ABSTRACT>A large stromatoporoid Actinostroma cf. crassipilatum Lecompte, 1951, at least 0.85m in height, occurs in the Sluchowice quarry, Kielce, Holy Cross Mountains. The sponge occurs in growth position within Early Frasnian (transitans Zone) intraclast-rich reef-rubble deposits. The unique preservation of the reef-builder close to a reef core is implied for the northern flank of the developing Dyminy Reef during the maximum expansion northward into the Kostomloty intrashelf basin. 8509 <TITLE>The palaeobiodiversity of stromatoporoids, tabulates and brachiopods in the Devonian of the Ardennes: changes through time.</TITLE>
8510 <SOURCE>Bulletin de la Societe Geologique de France 178, 5: 383-390.</SOURCE>
8511 <ABSTRACT>The specific biodiversity of stromatoporoids, tabulates and brachiopods from the Ardennes (706 taxa) has been analyzed stage-by-stage from the Lochkovian up to the Famennian. The diversity of each group may be correlated with external factors (e.g. facies), but it varied individually (e.g. decline of brachiopods in the Givetian). The faunas are discussed at the order level, however some more diversified orders are analyzed at family level. Biodiversity shows a single peak centered on the Givetian for the bioconstructors, and two major peaks (Emsian-Eifelian and Frasnian) for the brachiopods. The most diversified orders are Stromatoporellida (stromatoporoids), Favositida (tabulate corals) and Spiriferida (brachiopods). Stromatoporoids display two, tabulate corals four and brachiopods five stages of renewal of fauna.</ABSTRACT>

8562 <SOURCE>Bulletin de la Societe geologique de France 18, 6: 1699-1711.</SOURCE>
8563 <ABSTRACT>*Pleurodictyum kerfornei* Collin 1912 is designated as type species of the genus *Kerforneidictyum*. A way of fixation upon a non-fossilizable organism is described as well as the presence, in some species, of an arrangement of the septal ridges according to a *Tetracoralla* type of scheme. The microstructure shows lamellary cenenchyma and fibrous spines, the dark median line is granular. Some supports in favour of the phylogenetic connections between Tabulata and *Tetracoralla* are presented.</ABSTRACT>

8574 <TITLE>The tabulate coral *Hyostragulum*, an epizoan with bearing on hyolithid ecology and systematics.</TITLE>
8575 <SOURCE>Lethaia 9, 1: 51-64.</SOURCE>
8576 <ABSTRACT>The new, monotypic tabulate coral *Hyostragulum* and its type species *H. mobile* is described. This coral was found as an epizoan on the conch of different hyolithid species - and occasionally of nautiloids and gastropods - in the Bohemian and Moravian Lower and Middle Devonian. Moreover the authors discuss the validity of the hyolithid genus *Pterygotheca* Novak 1891, as also hyolithid ecology and systematic. The new hyolithid genus *Ottomarites* is established.

- Bergischen Landes (Rheinisches Schiefergebirge).</TITLE>
8614 <SOURCE>Palaeontographica A176 (4-6): 121-179.</SOURCE>
8615 <ABSTRACT>Middle and Upper Devonian Alveolitids and Heliolitids of the Bergisches Land, east of Cologne, were investigated and monographically described. 24 species of Alveolitids were found. Nine new species and one new genus were established. Among other criteria, statistical methods have been used in the characterization of the species. The colonial growth forms were reduced to three fundamental types. The microstructure of the skeleton (especially of the tabulae and the wall neighbouring the pores) were examined. Two budding types are described. The new alveolitid species are: *A. pseudorbicularis*, *A. bergeri*, *A. lindensis*, *A. bilsteinensis*, *Subalveolites praetenuissimus*, *S. parvicorallitus*, *Alveolitella schladensis*. The new genus *Spongialveolites* is characterized as follows: Diagnosis: Transverse sections of the corallites kidney-shaped. At the lower wall of the corallites a robust ridge is always developed. Pores of the wall numerous and large, mostly higher than wide. Many pores in the corners of the corallites are arranged in such a manner that two pores combine and mutually connect three corallites. Thickness of wall and distance of tabulae and pores are equal in the entire colony. Growth not known in detail and probably varying. Remarks: The genus is clearly characterized by large oval wall pores and the robust ridge at the lower wall of the corallites. The different species are differentiated only by the dimensions. Two new species are assigned to the genus: *Sp. minor* as the type species and *Sp. minimus*. Nine subspecies of *Heliolites porosus* (Goldfuss 1826) can be distinguished in this investigation area. Three new subspecies are established. Here, statistical methods are also used in the characterization and distinction of the subspecies. Some supplementary data are given concerning Goldfuss's originals of *Heliolites porosus* which had already been revised by Lecompte (1936). The submicroscopic structure of the skeleton as well as some perceptions on foreign bodies and parasites are described. The new species *H. bilsteinensis* and the new subspecies of *H. porosus*: *H. p. bergeri* and *H. p. schladensis* are assigned to line heliolitids. Finally, the stratigraphic range of the species and the facies in which they are found, are indicated.</ABSTRACT>

8640 <SOURCE>Acta Universitatis Carolinae Geologica 3: 251-259.</SOURCE>
8641 <ABSTRACT>Tabulate corals are sampled in the depth-interval between 1877.5 and 1901.7 m. Association of corals includes *Caliopora battersbyi* (Milne-Edwards et Haime 1851), *Scoliopora denticulata denticulata* (Milne-Edwards et Haime 1851) alpha morphotype (see text fig. 1), *Scoliopora minima* Nowinski (temporarily nomen nudum), *Natalophyllum ? dubiensis* Nowinski 1976, *Thamnopora bublichenkoi* Dubatolov 1962, *Crassialveolites crassus* (Lecpte 1939). The spectrum of present coral species indicates the *Caliopora battersbyi* acrozone. In the large appendix the biozones are defined on the basis of tabulate corals. Beginning from the bottom they are as follows: *Spongialveolites intermixtus* acrozone, *Trachypora dubatolovi* - *Scoliopora dubrovensis* coenozone, *Caliopora battersbyi* acrozone, *Alveolites mailleuxi* local problematic biozone, *Alveolites delhayei* acmezone, *Crassialveolites domrachevi* s. s. acrozone, *Scoliopora denticulata vassinoensis* acmezone. These biozones represent the time span from the upper Eifelian to the lower Famennian age.</ABSTRACT>

8653 <SOURCE>Bulletin du Museum national d'histoire naturelle 4 ser., 10, 1988, sec. C, 4: 307-341.</SOURCE>
8654 <ABSTRACT>Le genre monospécifique *Dendropora*, jusqu'à présent connu seulement par deux petits spécimens de musée, est redécrit sur la base d'un abondant matériel du Givetien de Belgique et du Boulonnais; celui-ci permet de préciser les caractères structuraux et microstructuraux de *Dendropora explicita* Michelin 1846. Le nouveau genre *Senceliaepora*, créé pour *S. tenuiramosa* n.gen., n.sp. se distingue du précédent par plusieurs traits morphologiques et microstructuraux; il est localement très abondant dans certains niveaux du Frasnien supérieur de Belgique et du Boulonnais. La position systématique des deux genres est discutée, ainsi que la définition de la famille *Dendroporidae* de Fromentel 1861.</ABSTRACT>

8665 <TITLE>A new *Parastriatopora* species (Anthozoa, Tabulata) from the Lower Devonian of Colle (Spain, Cantabrian Mountains).</TITLE>
8666 <SOURCE>Bulletin of Geosciences 80, 4: 287-290.</SOURCE>
8667 <ABSTRACT>The paleontological collection of the Museo Geominero (Madrid) houses a new species of the tabulate coral *Parastriatopora*. It comes from the Lower Devonian of Colle (Prov. León) and probably originates from one of the biostromal levels in the upper part of the

- Valporquero Formation and the Lower part of the Coladilla Formation (Upper Emsian). The new species, described under open nomenclature as *Parastriatopora* sp., is characterized primarily by its large corallites and calices: the 5- to 7-cornered calices are 3.5-6.9mm in diameter (mostly 5.5-6.0mm). Furthermore, it shows very interesting paleobiogeographical relationships, because the morphologically closest related species is *Parastriatopora gigantea* (Knod 1908) from the Lower Devonian of Bolivia. *Parastriatopora* sp. could be an example of a close relationship between the Cantabrian Mountains and America during the Emsian.

8718 <SOURCE>Senckenbergiana lethaea 79, 1: 63-87. [in memoriam Dr. Wolfgang Struve]</SOURCE>
8719 <ABSTRACT>Tabulate corals from the Lower/Middle Devonian boundary beds are described. The specimens were recovered from the middle Heisdorf Formation - lower Lauch Formation, ranging from the upper Emsian to lowermost Eifelian. The material was collected by Dr. Rolf Werner [†], Forschungsinstitut Senckenberg/Frankfurt, in the early seventies from new trenches ("Richtschnitte") in Wetteldorf (Pruem Syncline; Werner 1972a), Dingdorf (Pruem Syncline; Werner 1973b, 1975), Lissingen (Gerolstein Syncline, Werner 1973a, 1976) and the Lower/Middle Devonian profile "Ahuetter Kehre" (Hillesheim Syncline, Werner 1972b). The following taxa have been identified: Favosites (Favosites) gilsoni Lecompte 1939, Favosites (Emmonmsia) sollei (Birenheide 1985), and Squameofavosites straeleni Lecompte 1939; and Heliolites wernerii n.sp. is described. Investigation of microstructure in coral skeletons related to boring cyanophytes allows conclusions on the timing of the diagenesis to be drawn. Endobiotic worm-tubes of Chaetosalpinx huismani Stel 1978 are described.</ABSTRACT>

- 8756 <TITLE>Tabulate corals of Ibarmaghian affinities in the Upper Emsian of Bohemia.</TITLE>
- 8757 <SOURCE>Geologica et Palaeontologica 35: 31-51.</SOURCE>
- 8758 <ABSTRACT>Some tabulate corals belonging to a genus identified for the first time in the Barrandian area (Bohemia, Czech Republic) were collected in 1948-1950 by Jiri Bouska in the vicinity of Holyne. The fossiliferous beds of the Bouska excavation are assigned to the Trebotov Formation which belongs to the Upper Emsian (Upper part of P. serotinus Zone). This part of stratigraphic sequence consists of background sedimentation lime-mudstone, which alternates with fine-grained tentaculit-bearing and coarse-grained calciturbidites. Among the largely silicified tabulate corals - many of them still remaining undetermined - three new species have significant palaeogeographic implications, being inconsistent with previous knowledge of Bohemian coral biofacies. These species are Kerferoidictyum rex n.sp., Pterodictyum holynesis n.sp. and Taouzia vulvaria n.sp. During the Upper Emsian, these genera are typical for the Ibarmaghian Domain of the Gondwana margin (North Sahara, Iberian Peninsula and Armorican Massif) or in the Maghreb-European Realm

- (north Gondwana and Avalonia). Pterodictyum and Taouzia were formerly identified only in the Ibarmaghian Domain; Kerforneidictyum is widely distributed. The oldest occurrences of the latter genus are from the Lower Emsian of the North Gondwana Province, but this genus has also been recorded from the Uppermost Emsian of the Sauerland. The co-occurrence of Kerforneidictyum, Pterodictyum and Taouzia in the Upper Emsian of Bohemia indicates clear affinities with the Ibarmaghian Domain and gives supplementary evidence for retaining central Bohemia at the north Gondwana margin.

8770 <SOURCE>Geologica et Palaeontologica 15: 1-26.</SOURCE>
8771 <ABSTRACT>Because the type specimens of Pleurodictum problematicum Goldfuss 1829 are lost, a neotype is created here coming from the Lower Emsian of Oberstadtfeld/Eifel. Species range from the Upper Siegenian to the Lower Emsian/Upper Emsian boundary. The fossils can be found in life position only in the silty shallow water sediments together with many Chonetids, while well-preserved specimens coming from fine quartzitic sandstones show features of redeposition. Morphology and ontogeny of the specimens are studied in details. Quantitative analysis shows an anagenetic trend in the evolution of some characters. A proterogenetic trend is pointed out from PI. problematicum to PI. latum.

8782 <TITLE>The genus Caliapora Schlueter (tabulate corals) from the Devonian of Moravia.</TITLE>
8783 <SOURCE>Vestn. Ustred. Ustavu geol., 56 (3): 157-168.</SOURCE>
8784 <ABSTRACT>In the Middle Devonian limestone complexes in Moravia nine species of Caliapora, including three new species, have been found in total. This group of tabulate corals has been used in the solving of the Paleozoic biostratigraphy on the slopes of the Bohemian Massif. The paper also gives a short description of the phylogenesis and ecology of the Moravian members of the genus. [the species described are: Caliapora batterbyi (Milne-Edwards & Haime), C. venusta Yanet, C. robusta (Pradacova), C. reducta Yanet, C. plagiosquamata n.sp., C. chaetetoides Lecompte, C. uralica Yanet, C. ochoensis n.sp., C. celehovicensis n.sp.; Caliapora is mostly associated with semilagoonal environments or coral banks generated beneath the reach of more intensive wave action].

8795 <TITLE>Devonian tabulate corals from the deep boreholes located south of Brno. [in Czech, with English summary]</TITLE>
8796 <SOURCE>Biostratigrafie Paleozoika: 31-36; Hodonin.</SOURCE>
8797 <ABSTRACT>In the region described, the tabulate coral faunas are mainly associated with the lower part of the Devonian limestone complex. They are characteristic of dark coloured, partially dolomitized limestones of the semilagoonal facies and of coral bank facies. The flat fringing reef developing in the roof and comprising laminites and breccia intercalations as well as nodular limestone beds (Skocek 1978) ceases to include subfacies suitable to the growth of tabulate corals. The diversity of the corals decreases until they get gradually extinct. * The vertical trends in the evolution of tabulate coral assemblages in the southern region are similar to those in the central region (Hladil 1974). However, as can be concluded from the intermittently cored boreholes, the Frasnian associations of the southern region seem to restrict themselves even more pronouncedly to ramose representatives of the subfamily Natalophyllinae Sokolov. Lower Givetian age can be ascribed to the assemblage determined in the Menin-1 borehole, core No. 12: *Striatopora* cf. *devonica* Schlueter, *Thamnopora bilamellosa* Yermakova, *Th. tumefacta* Lecompte, *Caliopora taltiensis* Yanet, *Mastopora* sp., *Remesia* sp., *Crassialveolites crassus* (Lecompte), Cr. aff. *crassus* (Lecompte), *Natalophyllum* sp. A, *Scoliopora* ex gr. *denticulata* (Milne-Edwards et Haime). * The presence of *Chaetetes raritabulatus* Deng in core No. 27 of the Nemcicky-2 borehole seems to indicate Lower Givetian age as well. *Caliopora battersbyi* (Milne-Edwards et Haime) that is diagnostic in Moravia of the upper parts of the Givetian as high as the Givetian / Frasnian boundary was recognized only in core No. 26 from the Nemcicky-2 borehole. * Only *Scoliopora denticulata* (Milne-Edwards et Haime) and *Natalophyllum* sp. B are present in the Frasnian limestones.</ABSTRACT>

8822 <SOURCE>Vestn. ustred. ustavu geol. 62, 1: 41-46.</SOURCE>
8823 <ABSTRACT>The reef benthic communities had survived at Mokra in southern Moravia till the Lower Famennian age. Coral samples are dated by conodont fauna into upper part of the Palmatolepis crepida Zone (see Friakova et al. 1985). The Frasnian / Famennian boundary in southern Moravia is placed at the limit of the Lower and Middle Palmatolepis triangularis Zone, following the recently most acceptable conception (see Chlupac 1984). The taxa Scoliopora denticulata rachitiforma subsp. n. and Natalophyllum persicum sp. n. are newly described in the present paper.</ABSTRACT>

8835 <SOURCE>C. R. Acad. Sci. Paris 303, II/8: 761-764 [in French, with English summary].</SOURCE>
8836 <ABSTRACT>Polished slides have been cut in specimens of Ligulodictyum Plusquellec 1973 from the Lower Devonian of Finistere, France. In the axis of trabeculae are observed monocrystalline rods, whose diameter is distinctly greater than the one of the surrounding embossed fibers. We propose to call it cauliculae. The hyaline calcite which constitutes them is loaded with uniformly scattered particles. Cauliculae have been until now encountered in a single genus: therefore, any part can be attributed to them in systematics or phylogeny of the Tabulate corals.</ABSTRACT>

8848 <SOURCE>Neues Jahrbuch Geologie Palaeontologie Monatshefte 1989, 6: 356-374. [in German, with English and French summaries]</SOURCE>
8849 <ABSTRACT>Our revision confirms the validity of the genus Petridictyum Schindewolf 1958. Its distinctive features are the convex shape of the proximal surface, a concentric mode of budding around the protocorallite (= petrioid budding), a strong development of spiny septal crests apparently arranged in two cycles and lack of the commensal worm Hicetes. A more precise definition, including the microstructure, will have to await future studies of material that is not decalcified.</ABSTRACT>

8860 <TITLE>Ontogeny and astogeny in Aulopora and its significance, illustrated by a new non-encrusting species from the Devonian of southwest England.</TITLE>
8861 <SOURCE>Lethaia 23, 1: 61-75.</SOURCE>
8862 <ABSTRACT>A new non-encrusting species of Aulopora is described from the Middle Devonian of southwest England. Its colonial form is reconstructed from serial sections using a computer program. These sections also allow the description of protocorallite ontogeny and the formation of offsets in the new species. For comparison, aspects of ontogeny and astogeny were investigated in some other auloporids: protocorallite ontogeny and colony form in *Plexituba*? cucullina; increase in Aulopora serpens and Aulocystis sp. cf. A. amica. Most reptant auloporids show a more or less constant angle of offsetting to the parent, but in *P.*? cucullina, the interoffset angle decreases with each successive increase event in the colony. The phylogenetic significance of the auloporids is reassessed on the basis of these new data on protocorallite ontogeny and increase. [original abstract]</ABSTRACT>

8912 <TITLE>A new Aulopora from the Devonian of south-west England and its significance.</TITLE>
8913 <SOURCE>Proc. Ussher Soc. 7: 307.</SOURCE>
8914 <ABSTRACT>A new species of the simple tabulate coral genus Aulopora, from the Chercombe Bridge Limestone (Eifelian) of the Lemon Valley near Newton Abbot, South Devon, is free living. Its presence was detected in serial sections and its three-dimensional form reconstructed by computer. Members of this genus not occurring as weathered out encrusting material are probably much more common than recorded but usually escape detection. Characteristic features are only more apparent in sections cut in the plane of bedding, whilst most working sections are cut perpendicular to bedding. * The protocorallite of this new species shows the development of a macrospine in the plane of bilateral symmetry. Such a structure has not previously been described in a tabulate coral, but suggests comparison with the first formed counter-cardinal septal plate of rugose corals. In addition, the serial sections yield new information on the mode of origin of new corallites in the auloporid colony. * The pattern of offsetting compares closely with that seen in the genus Eofletcheria rather than with the mode typical of most tabulate corals. This supports an earlier deduction that Auloporu evolved from Eoflecteria in the Middle Ordovician, rather than the Russian view of Aulopora as ancestral to all tabulate corals (Scrutton 1984, 1990). 8939 <SOURCE>Paläontologische Zeitschrift 65, 1/2: 77-103.</SOURCE>
8940 <ABSTRACT>The species Roemeria bohémica Pocta 1902 has been revised on the basis of its original material and of topotypical specimens : its characters are in general consistent with those of Calamopora injundibulifera Goldfuss, 1829, type species of the genus Roemeria Milne-Edwards & Haime 1851. Roemeria bohémica is characterized by the numerous complex tabulae and the strong development of septal spines. These characters are considered by us of only specific importance and the genus Roemeripora Kraicz 1934, based on R. bohémica, is thus considered as a junior synonym of Roemeria . An exhaustive list of the Devonian species attributed to Roemeria or to Roemeripora is given.</ABSTRACT>

8952 <SOURCE>Revista Espanola de Paleontologia 7, 1: 3-12.</SOURCE>
8953 <ABSTRACT>Tabulate corals from the Lower Devonian Lorito Limestones (Cordoba Province) are described in detail and they are assigned to Parastriatopora ex gr. annulata (Le Maitre 1952), a group until now mostly known from North Africa and Armorica. The Lorito Limestones probably belong to the upper part of the Gedinnian, according to their

- tabulate coral fauna content. The microstructural evolution of the median lamina of the wall, from the axial part of the branches until the periphery, is described in detail. We observed a replacement of granules by elongated rods and, close to the surface of the corallum, a complete disappearance of any median structure. This feature is compared with other cases, of known branching tabulate corals.</ABSTRACT>

8977 <TITLE>El genero Caliapora (Tabulate) en el Devonico de la Cordillera Cantabrica (NW de Espana).</TITLE>
8978 <SOURCE>Revista Espanola de Paleontologia [special volume]: 58-70.</SOURCE>
8979 <ABSTRACT>The genus Caliapora Schlueter 1889 is subdivided in three subgenera Caliapora (Caliapora) Schlueter 1889, limited to the Givetian; Caliapora (Mariusilites) Mironova 1974 probably the direct ancestor of Caliapora (Caliapora) and known from the Lowermost Devonian until the Lower Givetian; and Caliapora (Luciaella) nov. subgen., from the Upper Emsian - Lower Eifelian of the Cantabrian Mountains (NW Spain). The genus Caliapora is recorded for the first time from the Cantabrian Mountains with Caliapora (Mariusilites) cf. chaetetoides Lecompte 1939 and Caliapora (Luciaella) daedala nov. sp. Some general considerations concerning the genus Caliapora are developed: the systematic position of the genus at familial level, the stratigraphical range of the different subgenera, the paleogeographical repartition and the paleoecological requirements.</ABSTRACT>

8990 <TITLE>Tabulate corals from the Givetian and Frasnian of the Holy Cross Mountains and Silesian Upland.</TITLE>
8991 <SOURCE>Acta Palaeontologica Polonica 37, 2-4: 183-216.</SOURCE>
8992 <ABSTRACT>Tabulate corals and single species each of the heliolitid anthozoans and chaetetid sclerosponges mostly from the Givetian and Frasnian stromatoporoid-coral series of the Holy Cross Mts and the Silesia-Cracow Region are reviewed from an ecological and

- stratigraphical point of view. *Thamnopora*, or the branched pachyporids, and massive alveolitids are usually the most significant reef-builders. The most distinctive fauna, with *Caliapora battersbyi* and *Heliolites porosus*, thrived in the earlier Givetian bank habitats. Late Givetian biostromal-complex associations with *Alveolites obtortus*, *Striatopora enigmatica*, and especially *Alveolitella fecunda*, as well as the succeeding Frasnian *Alveolites*-dominated reef-complex faunas with *A. maillieuxi*, and later with *A. tenuissimus*, *Aulocystis* and *syringoporids*, are far more uniform. In addition, a local *Coenites laminosa*-*Chaetetes yunnanensis* fauna is recognized in the Middle Givetian of the Kostomloty area. The transitional biogeographic position for Polish tabulate assemblages between Variscan Europe and Russia is clearly evident. Forty eight species have been identified. *Pachyfavosites polonicus* sp. n., *Striatopora enigmatica* sp. n., *Alveolitella polygona* sp. n., *Armalites minimus* sp. n., and *Syringoporella raritabulata* sp. n, *Alveolites edwardsi frasnianus* subsp. n., and *Caliapora battersbyi* minor subsp. n. are proposed.

9029 <TITLE>Korallen aus dem höheren Eifelium und unteren Givetium (Devon) des nordwestlichen Sauerlandes (Rheinisches Schiefergebirge). Teil I: Tabulate Korallen.</TITLE>
9030 <SOURCE>Palaeontographica A227, 4-6: 87-224.</SOURCE>
9031 <ABSTRACT>From the Middle Eifelian to the lower Givetian strata of the northwestern Sauerland (map sheet 4612 Iserlohn, 4711 Luedenscheid, and 4713 Plettenberg) are 29 tabulate coral species described. Informations about the type material and the previously known distribution are given for every species. The material has been collected mostly in the coral limestones of the Gruenewiese-Member (uppermost Eifelian) of the Ihmert-Formation and the Bredenbruch-Member (lower Lower Givetian) of the Unterhonsel-Formation. The subspecies Squameoalveolites strigosus cusanorum n.ssp. is new. Axuolites ? szechwanensis (Tchi 1964), Thamnopora urensis spinulosa Tchudinova 1970, Platyaxum (Platyaxum) cf. laminosum (Guerich 1896), Platyaxum ? (Microalveolites) leve leve (Tchernychev 1951), and Roemerolites brevis rhiphaeus (Yanet 1972) have been found for the first time in Central or western Europe. 7 other species are described from the Eastern Rhenish Massif for the first time as well. The correct name of the species known as *Caenopora placenta* is *Syringopora hanshanensis* Chow 1980. Many species show an important expansion of their known stratigraphical range. The most Devonian reef-builders allow only rough stratigraphical classifications.

9042 <TITLE>Thamnopora und verwandte astige tabulate Korallen aus dem Emsium bis Unter-Eifelium von Asturien (Devon; Nord-Spanien).</TITLE>
9043 <SOURCE>Geologica et Palaeontologica 27: 23-101.</SOURCE>
9044 <ABSTRACT>Eight species of ramose tabulate corals related to Thamnopora are described in detail from the Ferrones Formation (Lower Emsian to lower Upper Emsian) and the Aguion Formation (Upper Emsian) of the Raneces Group and the Moniello Formation (upper Upper Emsian to lowermost Eifelian) of the central Asturian coast as well as from the Valporquero Formation and the Coladilla Formation (Upper Emsian) of the La Vid group and the Santa Lucia Formation (upper Upper Emsian to lowermost Eifelian) of Asturias. Among them are two species and one genus new. Thamnopora ? sotoi n.sp. from the Upper Emsian shows strong and abundant squamulae. Oekentoropia n.gen., with the only one species Oekentoropia radigi n.gen., n.sp. from the Upper Emsian of Asturias, has thin, three-dimensionally connected branches with small Caliapora-like corallites. Thamnopora pulchra savitschevae Dubatolov 1964, Thamnopora irregularis Lecompte 1939, Thamnopora cervicornis (Blainville 1830), Striatopora tschichatschewi Peetz 1901, Parastriatopora fallatis Yanet 1968, and Parastriatopora obsolenta Dubatolov 1969 are found for the first time in the Emsian of Spain. These corals have only a little biostratigraphical importance. They show close palaeobiogeographical relations to Siberia. Furthermore are informations given about the fossil contents of the Valporquero Formation and then Coladilla Formation of the La Vid Group.</ABSTRACT>

9055 <TITLE>Die Gattungen Alveolites Lamarck 1801 und Squameoalveolites Mironova 1969 (Anthozoa, Tabulata) im unteren Mittel-Devon (Eifelium) der Dollendorfer Mulde / Eifel (Rheinisches Schiefergebirge).</TITLE>
9056 <SOURCE>Senckenbergiana lethaea 76, 1/2: 1-51.</SOURCE>
9057 <ABSTRACT>The stratigraphical distribution of the tabulate coral genera Alveolites Lamarck 1801 and Squameoalveolites Mironova 1969 from the lower Eifelian (Middle Devonian) of the Dollendorf Syncline / Eifel Hills (Rheinisches Schiefergebirge) has been examined in detail. Through investigation of the morphological characters it is possible to distinguish the following species at different stratigraphical levels: Alveolites suborbicularis Lamarck 1801, Alveolites edwardsi Lecompte 1939, Alveolites intermixtus intermixtus Lecompte 1939, Alveolites intermixtus minimus (Iven 1980), Alveolites megastomus Steininger 1849, Alveolites minutus Lecompte 1939, Alveolites subaequalis Milne-Edwards & Haime 1851, Alveolites crassus Lecompte 1939, Alveolites cavernosus Lecompte 1933, Squameoalveolites fornicatus (Schlueter 1889), Squameoalveolites robustus (Pradacova 1938) and Squameoalveolites straeleni (Lecompte 1939). The coral assemblage in the north-eastern part of the Dollendorf Syncline is dominated by faunal elements of the North Eifel area with a clear bohemian influence. In the south-western part of the syncline a typical south Eifel fauna can be recognized. In addition, a distinct faunal influence from the Ardennes (Belgium) can be recognized at some stratigraphical levels. The species Alveolites suborbicularis, hitherto considered as typical of Givetian and Frasnian deposits, occurs first in the upper Eifelian. Also remarkable is the first record of the species Squameoalveolites robustus (Pradacova 1938) in the upper Eifelian. This species was hitherto known from comparable sediments of Bohemia / Moravia, Russia and Austria. The occurrence of the rare species Alveolites megastomus Steininger 1849 in the Freilingen Formation is also of special interest. The preservation of the skeletal microstructure of the different species was examined particularly with respect to diagenetic alteration. There are numerous microstructures, which cannot be accounted for as of primary morphological origin. These secondary pseudostructures were caused by diagenetic recrystallization processes during fossilization.</ABSTRACT>

9068 <TITLE>Secondary microstructures in tabulate corals of the genus Alveolites Lamarck 1801 from the Middle Devonian of the Dollendorf Syncline (Eifel Hills, Germany).</TITLE>
9069 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 87-97.</SOURCE>
9070 <ABSTRACT>The skeletal elements of representatives of the genus Alveolites Lamarck 1801 from the Eifelian (Middle-Devonian) of the Eifel Hills (Rheinisches Schiefergebirge / Germany), especially from the Dollendorf Syncline, were investigated in detail with regard to

their post-mortem diagenetic changes. Numerous microstructures, which cannot be interpreted morphogenetically, have been recognized in the skeletons of diverse species of *Alveolites* Lamarck 1801. The present study is devoted mainly to the most important skeletal element of tabulate coral colonies, the wall, which is especially affected by post-mortem recrystallization due to fossilization. The new observations on *Alveolites* with a Scanning Electron Microscope gives impressive proofs that the primary skeletal microstructure of the wall has been partly replaced by different secondary textures and, moreover, has been thickened by deposition of cement A and additional overprinting as a result of diagenetic processes. As an important criterion of these different alterations of the original structure, recrystallization ("aggrading neomorphism") is indicated by the formation of coarse crystal aggregates, which appear in the shape of dark saw-toothed rhombs. Distinct cleavage structures in the neomorphic calcite have been observed as zigzag patterns and also as pseudolamellar structures. Last but not least, the recrystallization of syntaxial cements is a clear sign of diagenetic alteration.</ABSTRACT>

 9081 <TITLE>Tabulate Korallen aus der Curten-Formation (Mittel-Devon / Unter-Givetium) des Ahrtalprofils der Dollendorfer Mulde (Eifel / Rheinisches Schiefergebirge).</TITLE>
 9082 <SOURCE>Sonderveröffentlichungen, Geologisches Institut der Universität zu Köln 114 (Festschrift Eugen K. Kempf): 137-157.</SOURCE>
 9083 <ABSTRACT>The rocks of the Upper Curten Formation (Scheid Member) of the Ahr valley in the NE part of the Dollendorf syncline are very rich in a benthic fauna, especially in rugose and tabulate corals. The sequence is characterized by an interbedding of bituminous silty limestones, brown marly siltstones and marly shales. Special interest is laid on the Tabulata, which are present with some typical taxa for the lower Givetian of the Eifel Hills. The systematic description of this characteristic association within the Scheid Member of the Ahr valley section gives the first record of the following species for the Curten Formation of the northeastern Dollendorf syncline: *Favosites goldfussi* d'Orbigny 1850, *Pachyfavosites polymorphus polymorphus* (Goldfuss 1829), *Thamnopora cervicornis* (Blainville 1830), *Alveolites crassus* Lecompte 1939, *Scoliopora denticulata* (Milne-Edwards & Haime 1851), and *Roemerolites tenuis* (Schlueter 1885).</ABSTRACT>

 9094 <TITLE>Revised age of the Maly Bozkow limestone in the Klodzko metamorphic unit (early Givetian, late Middle Devonian) implications for the geology of the Sudetes, SW Poland.</TITLE>
 9095 <SOURCE>N. Jb. Geol. Palaont. Abh. 211 3: 329-353.</SOURCE>
 9096 <ABSTRACT>Interpretations of a Caledonian (early to mid-Devonian) tectono-metamorphic event in the Klodzko unit and therefore, throughout

- the entire west Sudetes were largely based on the assumption of a Silurian age for the limestones in the area of Maly Bozkow. Additional collection of tabulate corals, restudy of previous collections and confirmation of the presence of *Caliapora battersbyi* in the fauna indicate that the deposition continued in the basin into the Givetian. Consequently, deformation and metamorphism of the west Sudetes postdate the Middle Devonian and cannot be associated with the Caledonian orogeny. Post-Givetian tectonism in the Sudetes signifies that Variscan orogenesis was the pre-eminent event in the region, mixed paleogeographic characteristics in the maly Bozkow fauna suggest close proximity of the southern Laurussia margin to the northern Gondwana margin during the Middle Devonian.

 9108 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de Belgique, Sciences de la Terre 62: 23-41.</SOURCE>
 9109 <ABSTRACT>The original material of the three species from the Frasnian of Belgium formerly assigned to the genus *Cladochonus* McCoy 1847 by Lecompte (1939) has been revised. Two of these species are considered valid and maintained in the genus: *C. robustus* Lecompte 1939 and *C. maillieuxi* Lecompte 1939; *C. brevicollis devonicus* is for us a synonym of the last species. A microstructural study of *C. robustus* affords a useful comparison with the microstructure of typical *Cladochonus* from the Carboniferous. A systematical hierarchy of characters is proposed for the family Pyrgiidae De Fromentel 1861.</ABSTRACT>

9135 <ABSTRACT>In the Gib of Hampteau-sur-Ourthe several specimens of a new tabulate (coral) have been collected. The colony has a compact base from which rise blades of varying thickness. The arrangement of the individuals in the colony is the most unusual character of the genus: in the central part of the blade the corallites are prismatic and welded into a cerioid colony, while outside this they diverge from one another forming a phaceloid colony whose development often exceeds that of the massive part. The new tabulate is described and figured in detail. An attempt is made to assign it to its systematic position.</ABSTRACT>

9173 <SOURCE>Palaeontographica A153: 1-61.</SOURCE>
9174 <ABSTRACT>Research on the top of the Grauwacke of Faou and on the base of the Shales and Grauwacke of Reun ar C'Hrank lead to the proposal of a limit between the two formations. A new fauna consisting of Coelenterates, Trilobites, Crinoids and Tentaculitids has been found. A mixed fauna of Hercynian (Lower Zlichovian) and Rhenish (Lower Emsian) species is reported for the first time from the Median Armorian Synclinorium. The coral fauna is represented by the Tabulate families Cleistoporidae (Cleistodictyum porosum Plusquellec 1973) and Pleurodictyidae (Pleurodictyum microspinosum n.sp., Pl. latum n.sp., Pl. A, Pl. B, Petridictyum petrii (Maurer 1874)? and n.gen. ? n.sp.). This tabulate coral fauna - described by Y. Plusquellec - is of rhénane type.</ABSTRACT>

9186 <SOURCE>Acta Palaeontologica Polonica 21, 3: 293-309.</SOURCE>
9187 <ABSTRACT>The characteristics of a Tabulata assemblage from the Devonian of the Lublin area are given; the coral bearing strata are correlated with the Givetian of other parts of Poland as well as west and east European regions. * There is great similarity with the tabulate coral fauna of the Givetian of Belgium and also with that one known from the western Ural basin, but the fauna differ markedly in the specific composition from that one of the Central Devonian Field and of the South-East part of the East-European Platform.</ABSTRACT>

- 9213 <ABSTRACT>The new genus *Praemichelinia* (type species: *Beaumontia ? guerangeri* Edwards & Haime 1851) is described with special reference to the microstructure. The walls are built up by oblique and waved lamellae, whereas the dark median line shows a granulated microstructure in central parts of colonies; it becomes broader and fibrous to the periphery with perpendicular arrangement of the fibres. The genus ranges from upper Gedinian to the Carboniferous. The two subspecies *P. guerangeri guerangeri* Edwards & Haime 1851, and *P. guerangeri cryptospinosa* n.sp. are described. - 9226 <ABSTRACT>A new species of *Kerforneidictyum*, *K. oeslingensis* n.sp., is described. It is mainly characterized by the following features: apical angle reaching up to 160 degrees, deep calices with numerous small spines roughly of the same size, setted in two rows or scattered on septal ridges which are wider than the interseptal furrows, no obvious cardinal ridge, tabulae scarce or missing. The species has been collected in the lowermost Emsian of the Givonne-Eislek Anticlinorium in Luxembourg. It is 1) the first record of the genus in the Devonian of Luxembourg and 2) in the autochthonous part (SE Laurussia) of the Ardenno-Rhenish Mountains and 3) very likely the first - or one of the two first - representatives of the genus taking into account Gondwana and Laurussia. 9237 <TITLE>Parasites in Emsian-Eifelian Favosites (Anthozoa, Tabulata) from the Holy Cross Mountains (Poland): changes of distribution within colony.</TITLE>
9238 <SOURCE>The Geological Society, London, Special Publications 314 [Koenigshof P. (ed.): Case Studies in Palaeogeography and Palaeoecology]: 125-129.</SOURCE>
9239 <ABSTRACT>Organisms of unknown biological affinities, assigned to the genus Chaetosalpinx, are known to infest Palaeozoic tabulate corals and stromatoporoids. Analysis of distribution of these parasites, performed on Emsian-Eifelian material of Favosites goldfussi (Anthozoa, Tabulata) from the Northern Region of the Holy Cross Mountains (Poland), shows that parasites were absent in the early astogenetical stages, and that during astogeny both the absolute number of parasites per colony and the number of parasites per polyp were increasing. The latter can reach 2.7 parasites per polyp. Preferred settling places are in corallite corners (junction of three individuals), but dense infestation also produced settlement in the corallite walls (between two individuals). Probable causes of the increase are insufficient protection by host's cnidae, insufficient immune system response, and parasite ability to adapt to the host's defences. [original abstract]

9251 <SOURCE>Acta Palaeontologica Polonica 28, 3-4: 467-490 [for 1983]. <http://a.pp.pan.pl/article/item/app28-467.html></SOURCE>
9252 <ABSTRACT>Seventeen species of the Tabulata, including four new species and one new subspecies, have been described from the Givetian and Frasnian deposits of the Zerniki IG-1 borehole in the southern part of the Swietokrzyskie (Holy Cross) Mountains. The Givetian and Frasnian assemblages of Zerniki differ in their small taxonomic differentiation and in specific spectrum from assemblages found in other part of the Holy Cross Mts., Cracow Region and Lublin Region. * As compared with coeval assemblages of western (the Ardennes) and Eastern (the Urals, the East-European Platform) Europe, the Givetian and Frasnian assemblages under discussion are transitional in character. 9316 <SOURCE>Newsl. Stratigr. 31, 1: 25-37.</SOURCE>
9317 <ABSTRACT>Changes of function morphology are utilized for eventostratigraphical evaluations. 23 species from the subfamily Alveolitinae (tabulate corals) are studied on the background of 12 Middle to Upper Devonian stratigraphic levels of carbonate buildups in Moravia. Porosity, spinality and skeletization parametres have been caculated with the following interpretations: Two events re-presenting optimal reef conditions fall into the lowermost Givetian and the Upper Frasnian. The regressional event in the Upper Givetian is proved by this method, too. The impressive diminishing of variabilities is observed in the Upper Frasnian time-interval before the Kellwasser Event when Alveolitinae had extincted.</ABSTRACT>

9330 <ABSTRACT>Two new specimens of the rare tabulate coral Alveolites megastomus Steininger 1849 are described from the lower Middle Devonian (Eifelian) of the Eifel Limestone synclinorium (Rheinisches Schiefergebirge / Germany). One specimen originates from the Freilingen Formation of the Dollendorf Syncline; it is the first record from the Upper Eifelian of the Rheinisches Schiefergebirge. The second specimen comes from the upper Junkerberg Formation (Middle Eifelian) of the Pruem Syncline being the first proof in this Formation. The state of conservation of the skeletal microstrucure of both coralla is described and discussed.</ABSTRACT>

- 9368 <SOURCE>Geobios 38, 5: 677-683.</SOURCE>
- 9369 <ABSTRACT>Substrate specificity of Auloporida (Tabulata) from the skały Fm. (Upper Eifelian-Lower Givetian) of the Holy Cross Mts., Poland, has been recognized. Kyratrypa sp., a rare species in the formation (under 5%), was the most often encrusted brachiopod (59% of investigated specimens), while the most often occurring brachiopod, Aulacella eifeliensis (de Verneuil) was nearly not encrusted. The majority of encrusted brachiopods were larger than 20 mm, while smaller brachiopods occur abundantly in the Formation. The substrate specificity has been caused mainly by the ornamentation of the host's shell. The position of corallites along the commissure of the brachiopod shell proves that auloporids often encrusted living hosts. The epizoan probably used water currents produced by brachiopod's lophophore impoverishing the host's food composition, their relationship can therefore be described as scramble competition.</ABSTRACT>

9380 <TITLE>Tabules Auloporida du Givetien et du Frasnien de Ferques (Boulonnais, France).</TITLE>
9381 <SOURCE>Biostatigraphie du paleozoique 7 [BRICE D. et al. (eds)]: ...</SOURCE>
9382 <ABSTRACT>15 especes d'Auloporida sont reconnues dans le Givetien et le Frasnien de Ferques: Aulopora serpens Goldfuss 1829, A. sp. e.g. parva Lecompte 1939, A. stasinskae n.sp., A. cf. stasinskae, Plectituba ? cucullina (Michelin 1845). Plectituba briceae n.sp., Plectituba cf. briceae, Plectituba lata (Lecompte 1939), Aulocystis ? sp., Aulocystis jurkowicensis (Stasinska 1974), Chia polonica (Nowinski 1970), Syringopora cf. patula (Hinde 1890), Remesia crispa (Schlueter 1885), Roemeria infundibulifera (Goldfuss 1829), Thecostegites bouchardi (Michelin 1846). Le genre Aulostegites Lejeune est considere comme un synonyme probable du genre Aulopora; le genre Mastopora Sokolov, comme une forme de croissance particuliere des genres Aulopora et Thecostegites. L'analyse de la microstructure en lames minces a faces polies (LFP, Lafuste 1970) permet de reconnaitre des parois constituees, selon les genres, de lamelles, de microlamelles ou de fibres. Chez deux especes (A. serpens et T. bouchardi) une symetrie d'ordre douze apparait tres nettement. La faune decrite presente des affinites certaines avec celle connue en Ardennes (Bassin de Dinant), en Pologne (Monts Sainte Croix); il existe aussi des analogies entre les especes d'Auloporida du Frasnien de Ferques et des especes voisines du Devonien moyen des U.S.A. et du Canada.</ABSTRACT>

9407 <SOURCE>Geologica et Palaeontologica 28: 65-77.</SOURCE>
9408 <ABSTRACT>L'espece de corail tabule Aulocystis entalophoroides Schlueter 1889, du Devonien moyen, espece- type du genre Schlueterichonus Byra 1983, est redecrite sur la base du materiel original de Schlueter. Ses caracteres internes, inconnus jusqu'a present, sont precises: planchers developpes sous forme de grandes vesicules accolees aux parois, abondance des epines fusiformes inserees

dans les murailles ou reposant sur les planchers. La microstructure, remarquablement preservee, montre, autour d'une lame mediane constituee de granules et de biocristaux etires transversalement, des lamelles onduleuses longues; la premiere serie de ces lamelles forme avec la lame mediane un diedre ouvert vers le haut; les autres series sont disposees en chevrons plus ou moins reguliers. L'ensemble des caracteres structuraux et microstructuraux permet d'attribuer le genre Schlueterichonus a la famille Aulocystidae Sokolov 1950, au sein de laquelle il se distingue par son habitus branchu erige. Le genre est egalement represente dans le Devonien des Etats-Unis et d'Algerie.

9420 <SOURCE>Coral Research Bulletin 05: 141-149.</SOURCE>

9421 <ABSTRACT>Upper surfaces of the tabulae of Favosites sp. bear funnel-shaped depressions or elongated grooves. They are positioned close to the corallite axes. The tabulae bear flutings adjacent to the mural pores. Explanation of those structures by means of functional morphology analysis using the paradigm approach is attempted, with results supporting the conclusions of Wens (1969) and Sorauf (1974) on centripetal growth of tabulae and hydrostatic elevation of polyps.

9486 <ABSTRACT>The present article describes five different tabulate coral species of the families Micheliniidae and Cleistoporidae from the Emsian and Eifelian of various localities in northern and central Spain. The species Pleurodictyum elisabetae sp.nov. is erected. Michelinia guerangeri (Milne-Edwards & Haime 1851) and Cleistopora smythi Le Maître 1952 are described for the first time from Spain. The Spanish fauna's biogeographical relationships to France, Germany

- and northern Africa are very close. The Spanish fauna belongs to the Ibarmaghian Domain of the North Gondwana Province. The biostratigraphical value of the species found is very limited. </ABSTRACT>

9524 <SOURCE>Vestník Českeho geologického ústavu 68, 2: 27-42.</SOURCE>
9525 <ABSTRACT>Abundant tabulatormorphs and stromatoporoids settled the shallow water flanks of the Koneprusy islet elevations during the late and terminating Eifelian. Caliapora ex.gr. venusta, C. reducta, Spongioalveolites minor, Heliolites lindstromi, Celechopora devonica and Salairella spp. belong to the most common species. Many species flourished here earlier than around the Northern Devonian Continents. The coral / stromatoporoid assemblage above the dark beds (shallow water equivalent of the Kacak Shale) differs significantly from the pre-event assemblages. More diversified actinostromatids and

- alveolitids substituted the previous dominant species. Favosites goldfussi, Alveolites praetenuissimus and Heliolites intermedius are common, as well as Caliapora ex.gr. battersbyi.</ABSTRACT>

9576 <SOURCE>Biuletyn Instytutu Geologicznego 354: 125-144.</SOURCE>
9577 <ABSTRACT>The author has characterized Tabulata assemblages occurring

- in Eifelian deposits obtained from boreholes in the Gory Swietokrzyskie. She has described the state of preservation of the fossils and the frequency of the occurrence of Tabulata and the accompanying fauna in various lithological complexes. Eleven species of Tabulata and one species of Chaetetida have been determined. Among these, three species (*Thamnopora angusta* Lecompte, *Striatopora tenuis* Lecompte, *Cladopora tenuissima* Dubatolov) are described for the first time in Poland. Two species (*Gracilopora* sp. A and *Caliapora* sp. A) belong to genera which, so far, have been described in Poland from the Upper Devonian stages (Frasnian, Givetian). The author has distinguished index species of stratigraphic importance. The occurrence of the particular species and genera in the Kielce region and in the Bodzentyn syncline has been presented, as well as their stratigraphic range.

9614 <TITLE>Le Devonien du sondage de Nieuwkerke (Flandre Occidentale,
Belgique - extremite occidentale du Synclinorium de Namur).</TITLE>
9615 <SOURCE>Annales de la Societe geologique du Nord 108: 85-112. [in
French, with English summary]</SOURCE>
9616 <ABSTRACT>The hydrogeological reconnaissance borehole Nieuwkerke has
traversed the Givetian-Frasnian boundary. Different fossil groups
provide the framework for a biostratigraphic zonation. An ecological
break between a supratidal restricted environment and a subtidal open
marine environment has been observed in a carbonate sequence, which
precedes the biostratigraphic boundary based on conodonts. * Because of
its intermediate geographical position, the Nieuwkerke borehole can be
lithostratigraphically correlated with the Tournai region of the Namur
Synclinorium (Belgium) and the Ferques region in Boulonnais (N.
France). The lower unit is equivalent to the Mazy Formation and to the
Bastien Member of the Blacourt Formation but environmental instability
and biofacies variation observed at this level are probably due to the
regressive tendencies in the Uppermost Givetian at the southern margin
of the Brabant Massif. The upper unit can be easily correlated with the
lower part of the Bovesse Formation and with the lower part of the
Cambreseque Member of the Beaulieu Formation. The transgression which
nearly marks the base of the Frasnian has probably produced a more
regular and uniform facies distribution. * [in annexes described and
illustrated are *Disphyllum virgatum* (Hinde 1890) by M. Coen-Aubert and
Thamnopora polyforata (Schlotheim 1820), *Aulocystis* sp. and *Dendropora*
explicita Michelin 1846 by F. Tourneur.</ABSTRACT>

9654 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 273-283.</SOURCE>
9655 <ABSTRACT>Although stromatoporoids colonized the dead surfaces of coral skeletons there is also evidence for competition between stromatoporoids and caliaporids. Different species and genera of stromatoporoids display different abilities to attack the caliaporid corals. Actinostroma devonense was, at least in the Middle Devonian of Moravia (Central Europe), a dangerous killer of caliaporids. However, the representatives of the genera Trupetostroma, Hermatostroma and Clathrocoilon were less successful if forced into close, tissue-to-tissue competition. The caliaporids responded to the stromatoporoid attack using two strategies: escape and counter-attack. The close competition led to malformations in the tabulate coral skeleton, especially affecting the squamulae: reduction of squamulae to irregular thick spines is the major malformation trend.</ABSTRACT>

9681 <ABSTRACT>A new species of the genus Trypanopora (Sokolov and Obut 1955), T. conili, is described from the Couvin Limestone, Lower Eifelian of the southern margin of the Dinant Synclinorium (Belgium). Its morphological and microstructural characters are studied in detail. The stratigraphical and geographical distribution of the genus is summarized. The biological affinities of the family Trypanoporidae (Li 1981), successively compared with Tabulata, Annelida and Tentaculitida, are discussed; an attribution to the Polychaetes annelids is suggested. The relationships between the Trypanopores and their hosts - Chaetetids and Stromatopores - are examined: they formed mutual overgrowths.</ABSTRACT>

9731 <TITLE>A Lower Famennian fauna from the top of the reefoid limestones
at Mokra (Moravia, Czechoslovakia).</TITLE>
9732 <SOURCE>Newsletter for Stratigraphy 15, 1: 43-56.</SOURCE>
9733 <ABSTRACT>The five zonal divisions (conodont, foraminiferal, tabulate
coral, rugose coral, and stromatoporoid) are correlated in the Lower
Famennian Vilemovice Limestones (Macoča Formation). The age of the
reefoid limestones corresponds to the upper part of the *Palmatolepis
crepida* Zone. Stromatoporoid and formaminiferal fauna do not differ
substantially from the Upper Frasnian association in the bottom, some
differences were observed in the tabulate corals, while the rugose
corals show pronounced changes. (Original summary)The corals will be
described separately. Here only a list of species found in the section
is given:Tabulate Corals: *Scoliopora dentiaulata vassinoensis*
DUBATOLOV, Sc. *denticulatum* n. ssp., *Natalophyllum* n.sp., *Syringopora*
sp. Rugose Corals: *Alaiophyllum* ? n.sp., *Disphyllum* n.sp.,
Tabulophyllum n.sp. and *Rugosa* indet.</ABSTRACT>

9746 <ABSTRACT>Since 1970, an inventory of all the present fossil groups to
be found in the largest part of the Devonian series in the Ferques area
has been realized, after the establishment of the detailed
stratigraphic series and the updating of new outcrops (especially from
1975). This inventory has been established from all the old and recent

available material. The latter was collected bed by bed on the new outcrops, jointly by various specialists. Thanks to the exemplary collaboration of well informed amateurs such as Jean-Pierre Vidier and Christian Loones, the collection has been continued allowing new studies and discoveries. The studies and the systematic revisions, the definitions of taxonomic and biostratigraphic units were established with a concern for replacing the fossils in their sedimentary context, for giving their stratigraphic and biogeographic distribution in correlation with the international conodont scale. Since the publication of results, the Devonian conodont scale has been revised. Correlation between the old scale and the new one will be found in fig.1. The affinities of the flora and the fauna with those of the more or less remote regions were also analysed. The different taxa recognized in the Devonian of the Ferques area (more than 780) are listed below, following by one or several numbers referring to one or several papers where they are described or quoted. When a taxon has been revised, the paper quoting this taxon before the revision is not mentioned. These taxa belong to about twenty different fossil groups: Calcareous algae, miospores, acritarchs, chitinozoans, foraminifers, moravamminids, stromatoporoids, rugose and tabulate corals, bryozoans, brachiopods, bivalve and cephalopod mollusks, tentaculites, crinoids and echinida, trilobites, ostracodes, conodonts, vertebrate remains (ichthyofauna)

- 9784 <SOURCE>Acta Geologica Polonica 37, 1-2: 33-50.</SOURCE>
- 9785 <ABSTRACT>The stratigraphy and development of the Elbingerode Reef Complex (Harz Mountains) are presented in the light of conodont investigations. The Elbingerode Reef Complex, which developed on an isolated submarine volcanic rise within the Renish Trough, displays an atoll-like structure of facies pattern. Correlations based upon conodonts indicate the onset of reef growth in the Middle varcus Zone and its diachronous termination up to the Upper gigas Zone. The younger, post-reef sediments ranging up to the anchoralis-latus Zone are recognized as the neptunian dykes and the pockets within the reef carbonates. The termination of reef formation in the Elbingerode Reef Complex is interpreted as result of the increasing subsidence of the sea floor. The conodont distribution within the reef carbonates is restricted to the fore-reef facies, but no clear depth segregation of conodonts is observed. Differentiation of CAI values within the Elbingerode Reef Complex is also discussed.</ABSTRACT>

- 9810 <SOURCE>Palaeontology 44, 3: 447-488.</SOURCE>
- 9811 <ABSTRACT>The rich fauna of Late Devonian (late Frasnian) siliceous sponges from the Holy Cross Mountains, Poland is composed of 15 species and 11 genera. Both astylospongid demosponges (lithistids) and hexactinosan hexactinellids are present. The following new genera and/or species are proposed: *D. regukara* Rigby and Pisera sp.nov., *Jazwicella media* Rigby and Pisera gen. et sp.nov., *Astyloscyphia*

- irregularis Rigby and Pisera gen. et sp. nov., *A. turbinata* Rigby and Pisera gen. et sp.nov., *Astylotuba modica* Rigby and Pisera gen. et sp.nov., *Paleaoregulara cupula* Rigby and Pisera gen. et sp.nov., *Paleoramospongia bifurcata* Rigby and Pisera gen. et sp.nov., *Cordiospongia conicas* Rigby and Pisera gen. et sp.nov., *Paleoraticularia elongata* Rigby and Pisera gen. et sp.nov., *P. gigantia* Rigby and Pisera gen. et sp.nov., *Polonospongia devonica* Rigby and Pisera gen. et sp.nov., *P. fistulata* Rigby and Pisera gen. et sp.nov., *Urnospongia modica* Rigby and Pisera gen. et sp.nov., and *Conicospongia annulata* Rigby and Pisera gen. et sp.nov. The investigated fauna contains the youngest astylospongiids known and the oldest well-preserved and most diversified Palaeozoic hexactinosans. The sponge fauna constituted a significant element of a brachiopod-coral-sponge assemblage that inhabited a deep slope of the local Dyminy Reef structure, during its final phase of growth, in a clearly hemipelagic setting. This fauna is limited to the intrashelf depression within an incipiently drowned carbonate platform. </ABSTRACT>

- 9824 <ABSTRACT>with the exception of rock forming stromatoporoids and dispersed megascleres, fossil sponges were just recently recognized within the Devonian sequence of strata of the Bergisches Land. The specimens in question are preserved in original globular shapes exhibiting all the characters of a Rhagon-type sponge. Described under the name *Globispongia paffrathi* n.gen., n.sp., the fossils refer to *Astylospongiidae* Rauff 1893 on account of identical internal organization. The sponges were detected in a partly dolomitized, originally dark bed of limestone at the base of the Hornstein-Horizon, which is the youngest mappable unit of Middle Devonian rocks in the Bergisch Gladbach-Paffrather syncline.</ABSTRACT>

- 9837 <ABSTRACT>Tabulate corals are sometimes associated with other organisms occurring within their skeletons. These tabulate endobionts are common in Lower Palaeozoic (Ordovician and Silurian) and Devonian strata, but until now they have not been recognized in strata younger than early Frasnian. Here we report ?*Chaetosalpinx* sp. occurring within the skeletons of the tabulate coral *Yavorskia* sp. (Favositida, Cleistoporidae) from the latest Famennian ("Strunian") in the Etroeungt area (Northern France). It can be stated that these

- endobionts survived the Frasnian-Famennian boundary crisis and recovered in the Late Famennian.</ABSTRACT>

- 9850 <ABSTRACT>In the western part of the synclitorium median armoricaïn (Rade de Brest), the presence of Hyostragulum simplex n.sp. in the lower part of the Troan formation (Upper Emsian) is a supplementary element of hercynian fauna in Brittany during lower Devonian time. For the new species, characterized by lack of a septum on the base of the corallite (basal disc), a fibrous microstruture, perhaps trabecular, is shown. Pores are absent. Some tabulae are developed. Corallite diameters range between 1.2 - 1.9 mm (1.0 - 1.4 mm in the sense of measuring by Marek & Galle 1976). Thickness of the walls is 0.04 - 0.1mm. The systematic position of the genus - by Marek & Galle thought to be a representative of the suborder Alveolitina Duncan 1872 - is discussed but ending with the suggestion to let it remain incertae sedis.</ABSTRACT>

- 9862 <SOURCE>Aachener Geowissenschaftliche Beiträge 19: i-xi + 1-116.</SOURCE>
- 9863 <ABSTRACT>These investigation results relate to the Devonian Suchomasty limestone (upper Emsian - lowest Eifelian) and basal Acanthopyge limestone (Eifelian), which is restricted to the south-western area of the Barrandian (Czech Republic) known as the Koneprusy area. From the beginning of the Pragian stage to the beginning of the Eifelian stage, this region underwent its own course of development, independent of the other Barrandian area. The frequency and distribution of the bioliths, the associated fauna and the sediment structures of the Suchomasty limestone and the base of the Acanthopyge limestone indicate the formation of a shallow subtidal environment. The sponge-cement framestone which occurs only at the base of the Suchomasty limestone suggest that the palaeobathymetric position of the sedimentation area was more shallow than the several tens of metres generally assumed to date, at least at the beginning of the sedimentation of the Suchomasty limestone. 9875 <SOURCE>Beiträge zur Paläontologie 20: 113-121.</SOURCE>
9876 <ABSTRACT>Mud mounds in the Emsian of the Montagne Noire are built by red biomicrites and white sparitic layers. The latter fall into the category of stromatactis structures. Sponges and bryozoans are dominant in the micrites. The stromatactis structures are interpreted as spar-filled cavity-systems, which originated from microbial mats decaying in the sediment. The bryozoan / sponge community as well as the microbial mat community both contributed to the growth of the mounds. Mound growth was thus primarily biologically controlled, but influenced by sea level changes. Spectral analysis of detailed measurements of quarry sections revealed orbital cycles to be responsible for the sea level changes.</ABSTRACT>

9889 <ABSTRACT>The Upper Emsian mud mounds in the Montagne Noire are composed of interlayering red micrites and Stromatactis layers. Four types of Stromatactis were distinguished by their morphology and cementation pattern. The micrites are characterized by a baffling and / or binding microbial / sponge / bryozoan association. The formation of Stromatactis voids was caused by the decay of extensive microbial mats which proliferated during times of low or nondeposition. We present arguments for an early formation of the voids after the burial of the mats by increasing sediment influx, as well as for their early stabilization by cementation and by early lithification of the lime mud. The frequent changes from the microbial / sponge / bryozoan association to microbial mats were due to high-frequency sealevel fluctuations. The cyclic arrangement of Stromatactis layers is supposed to be caused by orbital cycles.</ABSTRACT>

</SOURCE>
- 9902 <ABSTRACT>The upper Emsian Suchomasty limestone and the Eifelian Acanthopyge limestone of the Barrandian are composed of red to gray biomicrites and white sparitic layers, which fall into the category of Stromatactis structures. A distinction of four types of Stromatactis fabrics by their morphology and cementation pattern is possible. The stromatactis fabrics of type A and B are interpreted as spar-filled cavity-systems, which originated from decaying microbial mats. Stromatactis type A occurs only in combination with sponge-cement framestones at the base of the Suchomasty limestone. This microfacies type probably documents an "embryonic" mud mound stage in the lowest suchomasty limestone. The occurrence of Sphaerocodium at the base of stromatactis fabrics type B indicates the origin of this stromatactis type due to former presence of "microbial mats". Concerning the distribution of the stromatactis fabrics type A and B in the section a change of sediment input was the dominant controlling factor.</ABSTRACT>

9966 <SOURCE>Vestnik Ustredniho ustavu geologickeho 54, 5: 179-183.</SOURCE>
9967 <ABSTRACT>In an abandoned quarry at Malhostovice, eastern margin of the Boskovice Furrow, a recrystallized reefal fauna has been found. From the determined corals, Crassialveolites domrachevi (Sokolov), Scoliopora denticulata vassinoensis Dubatolov and, according to A. Galle, Frechastreaa pentagona minima (Rozkowska) are bearing evidence of Upper Frasnian age. An isolated find of autochthonous corals bearing morphological features of the genus Caliapora is remarkable. However, the recrystallized material does not allow an unequivocal determination of their systematic position. With regard to the biofacies, this is the frontal margin of the reef core including a zone of a stromatoporoid block reef alternating with a zone of tabular alveolites.</ABSTRACT>

10031 <SOURCE>Geobios 8: 151-157.</SOURCE>
10032 <ABSTRACT>A Lower Devonian organic buildup (Moniello Formation) from

the Cantabrian Mountains (Asturias, NW Spain) displays a vertical paleoecological zonation reflecting different stages in the reef development. Four zones have been established, namely: stabilization, colonization, diversification and domination zones. The biologic and taxonomic composition of these zones as well as their lithofacies relations are indicated. Rugose corals (*Synaptophyllum*) played an important role as stabilizing organisms; the frame builders themselves (Stromatoporoids and Corals) also contribute to that function. Finally, the autogenic or allogenic character of the succession is discussed

10056 <TITLE>Reconstructing atoll-like mounds from the Frasnian of Belgium.</TITLE>

10057 <SOURCE>Facies 50, 2: 313-326.</SOURCE>

10058 <ABSTRACT>A succession of Frasnian mounds on the southern border of the Dinant synclinorium (Belgium) was investigated for their facies architecture, sedimentary dynamics and palaeogeographic evolution. Seven mound facies were defined from the Arche (A) and Lion (L) members, each characterized by a specific range of textures and association of organisms (A2/L2: red or pink limestone with stromatolites, corals and crinoids; A3/L3: grey, pink or green limestone with stromatolites, corals and stromatoporoids; A4/L4: grey limestone with corals, peloids and dasycladaceans; A5/L5: grey microbial limestone; A6/L6: grey limestone with dendroid stromatoporoids; A7/L7: grey laminated limestone with fenestrae; and A8/L8: grey bioturbated limestone). Laterally equivalent sediments include substantial reworked material from the buildups and background sedimentation. Textures and fossils suggest that A2/L2 and A3/L3 facies developed close to storm wave base, in a subphotic environment. Facies A4/L4, occurring near fair weather wave base in the euphotic zone, includes lenses of A5/L5 with stromatolitic coatings and thrombolites. A6/L6 corresponds to a slightly restricted environment and shows a progressive transition to fenestral limestone of A7/L7. This facies was deposited in a moderately restricted intertidal area. A8/L8 developed in a quiet lagoonal subtidal environment. The mounds started with A2/L2 or A3/L3 in which

- microbial lenses and algal facies A4/L4 became progressively more abundant upwards. Following 20m of laterally undifferentiated facies, more restricted facies occur in the central part of the buildups. This geometry suggests the initiation of restricted sedimentation, sheltered by bindstone or floatstone facies. The facies interpretation shows that after construction of the lower part of the mounds during a transgression and a sea-level highstand, a lowstand forced reef growth to the margin of the buildups, initiating the development of atoll-like crowns during the subsequent transgressive stage. The persistence of restricted facies results from the balance between sea-level rise and reef growth. [original abstract] </ABSTRACT>

10069 <TITLE>A fourth level of Frasnian carbonate mounds along the south side of the Dinant Synclinorium (Belgium).</TITLE>
10070 <SOURCE>Bulletin de l'Institut royal des Sciences naturelles de Belgique, sciences de la Terre 76: 31-51.
<http://hdl.handle.net/2268/19038></SOURCE>
10071 <ABSTRACT>An additional level of Frasnian mounds has been recognized in the La Boverie quarry at Rochefort and in four boreholes drilled in the Nord quarry at Frasnies, on the south side of the Dinant Synclinorium. It occurs between the Arche and Lion Members belonging respectively to the Moulin Liénaux and Grands Breux Formations, in the middle part of the stage. The new name of La Boverie Member is introduced at the top of the Moulin Liénaux Formation, for the deposits lying between the Arche and Bieumont Members; the latter is the basement of the Lion mound. The same succession has been observed in the sections of Moulin Bayot close to Vodelée, in the southeastern part of the Philippeville Anticlinorium. The La Boverie Member starts with rather deep bioclastic sediments, after the collapse of the carbonate factory at the top of the Arche mound. In the upper part of the lithostratigraphic unit, there is a thin buildup characterized by relatively shallow facies. The solitary rugose corals *Macgeea boveriensis* n.sp., *M. socialis* Soshkina, 1939 and *Sinodisphyllum posterum* (Ivaniya, 1965) collected in the lower part of the La Boverie Member are described in detail whereas the revision of *S. kielcense* (Rozkowska, 1979) occurring in the Bieumont Member is also provided.</ABSTRACT>

10083 <SOURCE>Geologica Belgica 8, 1-2: 69-89.
<http://popups.ulg.ac.be/Geol/document.php?ID=0562></SOURCE>
10084 <ABSTRACT>The facies architecture, sedimentary dynamics and paleogeographic evolution were reconstructed for a number of Frasnian buildups developed on a carbonate platform on the south side of the Dinant Synclinorium (Belgium). Bed-by-bed sampling and detailed

petrography were complemented by magnetic susceptibility analysis, allowing for high-precision lateral correlation. Six facies were recognised in the buildups, each characterized by a specific range of textures and assemblage of organisms: grey, pinkish or greenish limestone, with stromatactis, corals and stromatoporoids (facies A3-L3); grey limestone with corals, peloids and dasycladales (facies A4-L4); grey, microbial limestone (facies A5-L5); grey limestone with dendroid stromatoporoids (facies A6-L6); grey, laminar fenestral limestone, (facies A7-L7); grey, bioturbated limestone (facies A8-L8). The time-equivalent off-buildup sediments include a large amount of transported material that originally came from the buildups. Sedimentological evidence suggests that facies A3-L3 developed between the storm wavebase and the fairweather wavebase, in a oligophotic environment. This facies contains lenses of facies A5-L5, with stromatolitic coatings and Renalcis-rich thrombolitic bushes. These lenses were developed in greatest abundance closest to the fairweather wavebase, and they became anastomosing. Facies A6-L6 was developed in an environment with slightly restricted water circulation; there is a steady transition between this facies and the fenestral limestone A7-L7, which were deposited in a moderately protected subtidal to intertidal area. Facies A8-L8 developed at subtidal depths in a quiet, lagoonal environment. The buildups started with the development of facies A3-L3, with microbial lenses and algal facies becoming progressively more abundant upwards. Above about 20m in each buildup, more protected facies are found in the buildup's central part. This atoll-like geometry suggests the development of restricted sedimentation in this central area, sheltered by bindstone or floatstone facies. The initial development of the lower part of a buildup during a transgression and subsequent highstand would have been followed by reefal growth along the edge of the buildup during the succeeding lowstand; an atoll crown would then have started to develop during the following transgressive stage. The presence of restricted facies can be seen as the consequence of the balance between sea level rise and reef growth. [original abstract]

10095 <TITLE>Reefal and mud mound facies development in the Lower Devonian La Vid Group at the Colle outcrops (León province, Cantabrian Zone, NW Spain).</TITLE>

10096 <SOURCE>Facies 52, 2: 307-327.</SOURCE>

10097 <ABSTRACT>In the locality of Colle (Cantabrian Zone, NW Spain), the upper part of the Valporquero Shale Formation (Emsian, La Vid Group) contains an interval of shales and marlstones (barren, greenish-grey shales and fossiliferous, greenish-grey or reddish shales/marlstones) with beds and packages of homogeneous and cross-bedded skeletal limestones. Metrescale mud mounds and coral biostromes occur encased in the fossiliferous reddish and greenish-grey shales/marlstones, respectively, with the coral biostromes overlying conspicuous skeletal limestone bodies. These rocks were deposited on a carbonate ramp, ranging from above storm wave base for the cross-bedded skeletal limestones to below the storm wave base for the remaining deposits, organic buildups included. The vertical stacking of these facies and the occurrence of the two types of buildups are interpreted to reflect the interplay among several (possibly 4th and 5th) orders of relative

sea-level variations, during a 3rd-order highstand. Coral biostromes occur in early 5th-order transgressive system tracts developed within late 4th-order highstand, and are interpreted to have thrived on a stable granular substrate (skeletal limestones) in non-turbid waters, being later aborted by the onset of muddy sedimentation. Biostrome features suggest that they developed under environmental conditions essentially different from those related to the sedimentation of their granular substrate. Mud mounds occur in 5th-order transgressive and early highstand system tracts tied to early 4th-order sea-level rise. Field relationships suggest that mud mounds grew coevally with muddy sedimentation, with high-frequency variations in carbonate vs. terrigenous mud sedimentation influencing their development.

exposed in a quarry at Weinberg, in the western Hillesheimer Syncline.
At this locality, the Hallert Member of the formation reaches maximum
thickness. The basal carbonates containing Stromatactis, bryozoans,
sponge spicules, and phylloid algae are interpreted as mud mound
sediments. The mound appears to have developed above crinoidal detrital
limestones with incipient biostromes (upper Bohnert Member), whose
deposition was initially caused by exogenic factors, such as an elevated
position, and hydrodynamic processes, such as storms, and contour
currents. Detrital and reefal limestones, and dolomites with
stromatoporoids and chaetetids, occur above the mound sediments,
indicating shallowing. The younger inter-bedded bituminous limestones
and dolomites with Amphipora/stromatoporoid biostromes of the
succeeding Hallert-Lahr Member, were deposited in shallow quiet water,
and suggest increasing restriction of circulation within the basin.

10201 <ABSTRACT>The Marquise sheet in 1/50000 was published for the first time in 1971, just thirty years ago. During these three decades, several opportunities appeared: excavations for the foundation of a water-tower on Ferques area and some neighbouring houses, a new trench of railroad connecting Caffiers with Marbres du Boulonnais quarries, the extension of the Banc Noir quarry (also named Stinkal quarry… However, most of the old outcrops and most of the new ones which appeared between 1971 and 2001, are today in a very bad state of preservation, or of particularly difficult access or have disappeared. If the work of the last three decades was to be done again only with today's outcrops, the results would very probably not be the same.</ABSTRACT>

10239 <SOURCE>Acta Geologica Polonica 31, 3-4: 147-162.</SOURCE>
10240 <ABSTRACT>The Frasnian bioherms exposed along the southern limb of the Galezice syncline in the Holy Cross Mts., Central Poland, occur in the highest part of the stromatoporoid coral sequence, and their facies equivalent are chiefly the coral biostromes of the Upper Sitkowa Beds. In spite of small bathymetric differences between bioherms and biostromes, they contrast in ecology of the contained invertebrates, especially in brachiopod assemblages. The bioherms have developed in the belt on a gentle southern slope of the early Frasnian shallow-water carbonate bank of the Kielce region in the central part of the Holy Cross Mts. 10278 <SOURCE>Paläontologische Zeitschrift 62, 3-4: 175-192.</SOURCE>
10279 <ABSTRACT>The Massenkalk north of Brilon (East-Sauerland) and north of Balve (West-Sauerland) is of lagoonal character and is Upper Givetian (Middle Devonian) in age. Stromatoporoids, which can be subdivided into different growth forms (spherical to tabular, encrusting, thin lamellar, branching), are the main reef building organisms. The species of the branching stromatoporoid *Amphipora*, which are hard to distinguish, dominate. The two thin laminar species *Stromatopora cygnea* Stearn 1983 and *Stachyodes (Keega) joneirayi* Stearn 1975 are described for the first time from western Europe. Tabulate corals represent about 20% of the reef-builders and permit important inferences about the restriction of environment. Rugose corals and calcareous algae are rare. Reef dwelling organisms are less important; among these brachiopods, molluscs, foraminifera, calcispheres, and ostracods are, however, widespread. Several associations of reef-builders that depend on different water depths can be distinguished. Their composition varies according to the restriction of environment. With increasing water depth water energy increased on the carbonate platform. The analysis on the stratigraphical distribution of the species of the reef-builder fauna allows no more but vague stratigraphical classifications.</ABSTRACT>

10290 <TITLE>Structure and Microfacies of Middle and Upper Devonian Carbonate Buildups in Moravia, Czechoslovakia.</TITLE>
10291 <SOURCE>Canadian Society of Petroleum Geologists, Memoir 14 [McMillan N. J. et al. (eds): Devonian of the world], vol. 2: 607-618.</SOURCE>
10292 <ABSTRACT>The most bulk (98%) of the carbonate buildups are developed on Proterozoic crystalline basement blocks. Lagoons with mud banks and patch reefs range in width from several to several tens of kilometres but the reef margin is very narrow, only some tens or few hundreds of metres wide. Thickness of the buildups is generally between 200 and 1000 m. The mean subsidence rates, calculated according to buildup thickness and duration of the buildup accumulation, varied from 20.0 to 86.7 m Myr⁻¹. The platform margin has a general retreating trend up to the upper Frasnian *Palmatolepis gigas* Zone, when an advancing trend started. Coral-stromatoporoid benthic communities are present from Eifelian to the lower Famennian *Palmatolepis crepida* Zone. Four megacycles occur which display a general succession of dark wackestones, *Amphipora*-bearing rocks and boundstones. These megacycles culminate in (1) the Eifelian-Givetian boundary interval, (2) the upper part of the middle-Givetian, (3) the lower Frasnian, and (4) the uppermost Frasnian. These culminations are characterized by maximum rates of buildup accumulation and also the synchronous deposition of black anoxic sediments (generally in deeper environments.- the otomari, Phaceras, Manticoceras and Kellwasser events). The volumes of limestones corresponding to the standard microfacies (in the sense of

Fluegel 1978) were calculated with following results: standard microfacies No. 9 (SMF 9) - biomicritic limestones with bioclasts, 39,4 %, SMF 7 - biolitic limestones, 23.7%, SMF 8 - biomicritic limestone with biomorphs, 7.4%, etc. The abundant micrite formed in a variety of ways, partly mechanical, partly algal and other biochemical origins. Cementation at various stages completely fills porosity except for dolomitized and fractured horizons. The 129 microfacies which were distinguished during the evaluation of the material are reclassified according to the standard microfacies system (in the Fluegel's sense) as well as according to Devonian microfacies associations and Devonian development stages systems (in the sense of the author, Hladil 1986). The quantitatively restricted dependence is shown in Table 1.

10303 <TITLE>Selected benthic faunas from the Devonian of the Ardennes: an estimation of palaeobiodiversity.</TITLE>

10304 <SOURCE>Acta Geologica Polonica 57, 2: 187-204.

<http://www.geo.uw.edu.pl/agp/table/abstracts/57-2.htm></SOURCE>

10305 <ABSTRACT>A survey of the principal benthic faunas from the Devonian of the Ardennes is presented. The alpha-diversity is very high (707 species, including 138 species of stromatoporoids, 113 species of tabulates, hydroids and chaetetids, and 456 species of brachiopods). Analysis of their distribution through time indicates two brachiopod diversity peaks (Emsian/Eifelian and Frasnian), a single stromatoporoid diversity peak (Givetian), and no clear peak of tabulate corals (with the highest diversification during the Eifelian-Frasnian). The highest diversity of bioconstructors in the Givetian correlates with a decrease in brachiopod diversity. Changes in the vertical distribution of the faunas are correlated with the facies development: the development of carbonates correlates with the abundance of stromatoporoids and tabulates, while brachiopods were most abundant before and after the peak of carbonate development. Bioconstructors are absent (or nearly absent) in siliciclastic facies.</ABSTRACT>

10317 <SOURCE>Canadian Society of Petroleum Geologists, Memoir 14 [McMillian N. J., Embry A. F. & Glass D. J. (eds): Devonian of the World], III: 633-645.</SOURCE>

10318 <ABSTRACT>This paper discusses contemporaneous knowledge of conodont, foraminiferal, stromatoporoid, tabulate and rugosan faunas through the Devonian carbonate platform of Moravia. In basal parts of the Moravian Devonian, upper Emsian to lowermost Eifelian is documented by

conodonts. In the Jeseniky Mts conodonts are rare in the Middle Devonian and the Middle / Upper Devonian boundary is not yet documented by conodonts. The most important change in the conodont assemblage lies in the upper part of the Pa. triangularis Zone in Moravia; for detailed zonation of Famennian, the system based on phylogeny of Palmatolepis is accepted. Five foraminiferal zones correlated with the standard conodont zonation are distinguished in the Upper Devonian. Several stromatoporoid assemblages were distinguished in the interval from Eifelian to Frasnian; stromatoporoids pass into the Famennian. Eight tabulate coral biozones are known at present, some of which are capable of more detailed division. Biostratigraphically significant tabulates range from Eifelian to the Famennian Pa. crepida Zone. Seven rugose coral biozones are described, ranging from Eifelian to the upper Frasnian Pa. gigas or Pa. triangularis Zones with a local fauna known from the Famennian Pa. crepida Zone. Stromatoporoid and coral faunas are correlated with standard conodont zonation of the Upper Devonian. Stromatoporoid and coral shallow water faunas locally pass from upper Frasnian to Famennian without pronounced systematic changes. However, both diversity and abundance of coral and stromatoporoid faunas decrease noticeably across the Frasnian / Famennian boundary beds.

10370 <ABSTRACT>In talus limestones of the cap-stage (Frasnian) within the reef complex of Elbingerode/Harz Mts. it succeeded to prove a mud mound with characteristic features. * Mud mounds are hill-shaped lime mud buildups without framework accumulated in open-marine quite water. Their identity is proven by a matrix of mud- and wackestones, stromatactis, zebra limestones, and stromatolitic bindstones in the upper parts. Microbial communities, presumably cyanobacteria are considered to be the essential creators of the matrix, of the zebra limestones and of novel types of stromatolites (Ursoscopulus). They accumulated hill-shaped during a rhythmical process of formation together with finest remains of plancton and undergo permanent superficial sedimentary slide actions decomposing the primary structures.</ABSTRACT>

10382 <SOURCE>Fortschr. Geol. Rheinld. u. Westf. 35: 57-74. [in German, with

- English and French summaries] </SOURCE>
- 10383 <ABSTRACT>The worldwide Devonian reef growth was terminated in large areas during the triangularis and gigas zone (Upper Devonian I / δ). To explain this phenomenon six profiles with the transition from reef to non-reef facies ranging from Namur (Belgium) to Wuppertal (Germany) were investigated microscopically and geochemically. It turned out that the periodically increased production and sedimentation of clayey and mainly organic material directly controlled the Upper Devonian reef growth and finally caused its termination. Increased plate tectonical shifting of the land areas during the Upper Devonian finally triggered off the following chain of events: increasing rates of periodical rainfalls - intensified spreading of land plants - increased chemical weathering - periodically increased transport of nutrients and clastic material into the reef habitat - increased production and sedimentation of phytoplankton - termination of reefgrowth - finally euxinic sedimentation (Lower Kellwasser limestone, Upper Devonian I δ). </ABSTRACT>

- 10408 <SOURCE>Facies 23: 97-108. </SOURCE>
- 10409 <ABSTRACT>The Elbingerode Reef developed on a volcanic rise within the Rhenish Trough of the Variscan Geosyncline during the upper Middle Devonian (Givetian) and early part of the Late Devonian (Frasnian). Reef development can be recognized in the Elbingerode Complex from the varcus Zone up to the gigas Zone of conodont chronology. Volcanic activity came to an end in the Elbingerode Complex nearly isochronously within the Middle and Upper varcus Zone (iron-ore bed). Reef growth started in the upper varcus Zone (Middle Devonian). The lithology of the reef limestones permits a general distinction between peripheral detrital reef limestones (fore-reef) and lagoonal limestones (back-reef). Unbedded reef debris characteristic of the outer reef flank is represented mainly by rudstones and packstones. The biogenes are clasts of corals and stromatoporoids. This facies type contains conodonts. In the lagoon facies mudstones and grainstones with peloids are abundant. Stomatactis and birdseye structures are characteristic.

The bedded limestones of this region mainly contain amphiporoids, gastropods, brachiopods, calcispheres and foraminifers, and only subordinate stromatoporoids and corals. The back-reef limestones generally lack conodonts. A division of the reef complex into back-reef and fore-reef areas is only possible for the Middle Devonian (pre-rotundiloba interval). The lagoon was filled during the Late Devonian (Lower asymmetricus Zones), so that younger reef limestones (asymmetricus to gigas Zones) lack a back-reef sedimentation (cape stage). The central Elbingerode Complex displays the palaeogeographical picture of an atoll with a leeward lagoon and an outer circle of calcareous reef debris. The Neuwerk and Buchenberg anticlines and other anticlines were originally volcanic rises extending in front of the atoll in a bathymetric deeper position and with an independent sedimentation. The transgressive character of reef development (formation of a so-called reef onion) is deduced from the dip of the bedding of the reef limestones. The sequence reef limestones - brachiopod limestones (post-reef limestones) - pelagic post-reef limestones also provides good evidence that the end of the reef development was caused by an increasing subsidence. The reef growth in the Elbingerode Complex terminated in different places at different times. The last sign of reef building is known from the Upper gigas Zone. The end of the Devonian reefs and the beginning of the flysch stage are genetically and temporarily related, but took place regionally separated from each other. </ABSTRACT>

10420 <TITLE>Sédimentologie, paléoécologie et paléontologie des calcaires crinoïdiques au voisinage de la limite Couvinien-Givetien à Wellin (bord sud du Synclinorium de Dinant, Belgique).</TITLE>

10421 <SOURCE>Mémoires pour servir à l'Explication des Cartes Géologiques et Minières de la Belgique 31: 1-61.</SOURCE>

10422 <ABSTRACT>The sedimentology of the Eifelian-Givetian boundary beds in the wellin area indicates a transition from a siliciclastic-carbonate ramp to a gently sloping carbonate platform lacking a true reefal barrier. Prograding decametric sedimentary units form a littoral accretion megasequence. Corallian megafauna and algal microflora are highly diverse and abundant. Several communities are recognized in the ramp but they cannot be used for precise chronostratigraphic correlations. Comparison with other regions of the Dinant Synclinorium shows that the basin was already partitioned into blocks in Late Eifelian time. In Early Givetian several blocks of plurikilometric extension are identified. In this context, recognition of a new formation, provisionally called 'Formation X', between the Jemelle and Hanonet Formations, is significant. This local unit, some 120 meters thick, is composed of crinoidal and reefal limestones and indicates the existence of a sharply subsiding block in the wellin area.</ABSTRACT>

Rheinisches Schiefergebirge) in der Sammlung des Staedtischen Museums
Menden.</TITLE>
10447 <SOURCE>Geol. Palaeont. westfalen 17: 7-42. [in German, with English
summary]</SOURCE>
10448 <ABSTRACT>The Municipal Museum Menden / Sauerland possesses extensive
fossil collections from the northwestern Sauerland and its
neighbourhood out of the Givetian strata Oberhonsel-Formation,
Massenkalk, and Flinz. This collection was founded in 1912-1939 in
cooperation with K. Torley. Brachiopods and reef builders (corals and
stromatoporoids) are the most important fossil groups. The
re-examination of the collection gave some new (bio-)stratigraphical
information. The upper part of the Oberhonsel-Formation is as old as
the Dreimuehlen-Formation in the Eifel. Following species are described
for the first time from the Eastern Rhenish Schiefergebirge: the
tabulate coral Aulopora lata Lecompte 1939, the rugose coral
Siphonophrentis cantabrica Birenheide 1978, and the brachiopods
Spinatrypa orthodina Copper 1967, Spinatrypa girzenensis Copper 1967,
and Desquamatia (Variatrypa) ajugata Copper 1965. The anarcestid
cephalopod Sobolewia amplorotundata (Torley 1908) is figured for the
first time. Other Givetian fossils are listed as well as figured.
[original summary] Briefly described and figured is the species
Battersbyia aff. conglomerata (Schlueter 1881), and only figured is
Endophyllum bowerbanki Milne-Edwards & Haime 1851.</ABSTRACT>

Elbingerode Reef Complex in the Harz Area (Germany).</TITLE>
10460 <SOURCE>Facies 25: 1-50.</SOURCE>
10461 <ABSTRACT>The Givetian to Frasnian Elbingerode Complex, situated in the
Harz area (Germany), corresponds to an atoll-like reef formed by corals
and stromatoporoids on a group of submarine volcanoes. Circularly
arranged stratovolcanoes enclosed a central lagoon containing up to 600
m of Givetian backreef limestones. Three of the four volcanoes were
surrounded by fringing reefs; one of them remained permanently in a
deeper water position. Limestone sedimentation and reef growth were
controlled by differential synsedimentary subsidence of blocks and by
eustatic sea-level fluctuations. [first fragment of extensive summary]

10473 <SOURCE>Geolines 3: 38-49.</SOURCE>
10474 <ABSTRACT>Data concerning the influence of the jugleri Event on reef building organisms in the western Sauerland (Eastern Rhenish Massif, Germany) includes: Cultrijugatus Beds are Upper Emsian to Lower Eifelian and consists mainly of sandy silt- and mudstones with shallow marine fauna. It is proved by brachiopods, that the upper part of the Cultrijugatus Beds is of Lower Eifelian age. With no break, fossiliferous, marly beds of the Hobracker Formation (without Paraspirifer) follows above. The upper part of the Cultrijugatus Beds contains very fossiliferous coral limestones. The majority of coral and brachiopod species continued to overlying beds with no visible mass extinction by the jugleri/Chotec Event. Probably, this event was not very important for corals and stromatoporoids. [last fragment of extensive summary]</ABSTRACT>

10538 <SOURCE>Bulletin de la Societe belge de Geologie 100, 1-2: 57-119.</SOURCE>
10539 <ABSTRACT>The Frasnian-Famennian limestone sequence of Lesni Lom displays a series of significant gaps, especially at a stratigraphical level encompassing the final Late Pa. rhenana Zone and the Early Pa. triangularis Zone. Mixed nearshore and nektonic / pelagic faunas, as well as mixed allochems derived from a large spectrum of facies belts, point to an inclined outer carbonate ramp depositional environment. The maximum water depth probably exceeded several tens of meters. However, extreme and short-term sea-level falls around the Frasnian-Famennian (F-F) transition might have stripped a substantial part of the sedimentary cover on this ramp. The presence of an increasing amount of unstable siliciclastic grains, followed by the influx of lateritic and ferruginized particles are typical for the Lesni Lom F-F sequence. This

can be correlated with an oolitic ironstone level, which has been described from an inner ramp sequence at V Habesi. The latter iron-horizon, resembles the Famennian ironstones of Belgium, but it has also good analogues in the F-F sequences of the Russian Platform. Rebuilt corals and foraminifers seem to indicate different biotic and environmental controls, separately on the outer and/or inner ramp. Although more than twenty groups of taxa are discussed, only four of them - corals, fish remains, foraminifers and conodonts - have been described in detail. [original summary] The new coral species (Tabulata) *Scoliopora tetralobata* Hladil et Berousek sp.n., *S. relictata* Hladil et Berousek sp.n., *Coenites otavai* Hladil et Berousek sp.n., *Alveolites tenuissimus junior* Hladil et Berousek subsp. n., and (Rugosa) *Phillipsastrea zerda* Galle sp.n. have been established.

10563 <TITLE>Evolution of the bank to reef complex in the Devonian of the Holy Cross Mountains.</TITLE>

10564 <SOURCE>Acta Palaeontologica Polonica 37, 2-4: 87-182.</SOURCE>

10565 <ABSTRACT>Givetian and Frasnian stromatoporoid-coral limestone of the Kowala Formation in the southern Holy Cross Mts is subdivided stratigraphically, and correlated with strata elsewhere on the basis of identified sea-level cyclicity, with support from conodonts and other selected benthic fossils. After the Eifelian hypersaline sabkha phase, an extensive two-step regional colonization of the Kielce Region carbonate platform took place during the Eifelian/Givetian passage interval and the Middle Givetian. At least four deepening pulses resulted in intermittent drowning of the vast carbonate platform and sequential replacement of the undifferentiated *Stringocephalus* biostromal bank by the Sitkówka bank complex and, subsequently, by the Dyminy reef complex. The reef developed in the central Dyminy belt as result of the early Frasnian accelerated sea-level rise after some period of biotic stagnation near the Givetian-Frasnian boundary. Final demise of the reef resulted from combined eustatic and tectonic

- movements during the late Frasnian major crisis interval. [original abstract]

- 10591 <ABSTRACT>Initial stages of Givetian reefs in the Rhenish Schiefergebirge are characterized by short-term primary and/or secondary ecological successions. Complete sequences from the start of the substrate colonization to the end of the (first) domination stage do not exceed 75 cm. The guild composition of colonization, diversification and domination stages (sensu Miller 1991) depends on the paleogeographic situation, the water energy and in particular on the terrigenous input. High clastic influx led to numerous repetitions of the colonization stage without the development of diversification and domination stages. Good environmental conditions allowed the development of primary and/or secondary successions from the colonization stages to the diversification and domination stages. In such reef sequences the limestones, up to some 100 m thick, consist of repetitions of the diversification and/or domination stages.</ABSTRACT>

10602 <TITLE>Controls on the Origin and Composition of a Devonian Mud Mound (Frasnian of the Harz Mountains) with Special Respect to the Construction and Formation of Zebra-Limestones.</TITLE>
10603 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
10604 <ABSTRACT>Mud mounds are special cases of local hill-shaped marine accumulations of stromatactis-bearing carbonate mud. In contrast to reefs, a rigid framework of bioconstructors is absent. The investigated Upper Devonian Ruebeland Mud Mound in the Harz Mountains is completely constructed by black and white micrites with stromatactis. Intercalated are stromatolites and zebra limestones. The carbonate mud buildup was essentially accumulated and early cemented by microbial activities. Within the sediments of the whole buildup a distinct rhythmicity between spreading of microbial mats respectively the formation of white mudstones and real sedimentation of microfossiliferous wackestones is indicated. Thrombolitic mudstones, spar layers and stromatolites are of microbial, mostly cyanobacterial, genesis. Main controlling factors on Ruebeland mud mound growth are endogenic block movements and the rhythmical exogenic efficiency of microbial colonies. Hexactinellid sponges are the only macrofossils. Their issues seem to play a second order role in formation of carbonate mud. Most important for micrite formation of the white mudstones are micritized and lithified, laterally extended cyanobacterian colonies (cf. Epiphyton sp.) representing about 40-50% of the whole mound matrix.</ABSTRACT>

10616 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 023-033.</SOURCE>
10617 <ABSTRACT>The laterally equivalent Portilla and Candas Formations (Givetian-earliest Frasnian), a dominantly carbonate succession with reef-bearing intervals, was deposited in a carbonate ramp setting, zoned into a backreef lagoon, a reef tract and a calcarenite forereef belt distally grading to outer shelf marls and terrigenous mudstones. Sequential facies analysis of the reef-bearing intervals produced a model of ramp evolution. The succession is arranged in sequences up to several tens of metres thick. Each sequence has a sharp to rapidly transitional base and splits into a lower transgressive subsequence (commonly very thin or absent) and an upper regressive one. Reefs, when present, cap the regressive subsequence. [first fragment of extensive summary]</ABSTRACT>

10628 <TITLE>Discrimination between facies and global controls in isotope composition of carbonates: carbon and oxygen isotopes at the Devonian reef margin in Moravia (HV-105 Krtiny borehole).</TITLE>
10629 <SOURCE>Journal Czech Geol. Soc. 42, 1-2: 1-16.</SOURCE>
10630 <ABSTRACT>Relations among the isotope ratios, chemical composition, sedimentological features, eustatic fluctuations and diagenetical history have been documented from the reef / basin transition in the Moravian Karst (Krtiny HV-105 borehole). The $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ values of the Late Devonian limestones are within the ranges for the Late Devonian marine sedimentary environment. Nevertheless, the originally diverse isotopic compositions of the fossils and other rock components were changed in closed marine pore-water / rock systems, under conditions of rapidly decreased permeability. In the studied sequence $\delta^{13}\text{C}$ values of 2 to 2,5‰ are characteristic for bioherms, parts of the fore-reef to off-reef slope, and offshore lagoons. The $\delta^{13}\text{C}$ values close to 0 are characteristic for shallow-back-reef. The low $\delta^{13}\text{C}$ values of reef margin developed during the occasional emergence of this facies. A significant anomaly in $\delta^{13}\text{C}$ values (up to +5.5‰) has been documented at the transition between the proximal and distal forereef in the Pa. transitans Zone of the Early Frasnian, just before the maximum sea-level rise. This unusual positive excursion of the $\delta^{13}\text{C}$ values does not correspond to the global-event anomalies. The existence of this anomaly on the slope of the Moravian Karst is tentatively explained by a local IIIrd-category upwelling, a result of the diversion of the deeper contour and shallower wind-driven currents away from the shore. This anomaly corroborates the hypothesis of a strong facies control of the $\delta^{13}\text{C}$ content in carbonates.</ABSTRACT>

10642 <SOURCE>Dortmunder Beitrage Landeskunde., Naturwissenschaft Mitteilungen 31: 127-135.</SOURCE>
10643 <ABSTRACT>In this paper reasons are given why the Massenkalk reefs (Middle δ^{38} ; Upper Devonian) of the Sauerland are not comparable to modern coral reefs. A new model is developed explaining the observed carbonate facies without contradiction. This model assumes that the δ^{34} reef cores δ^{34} of the Massenkalk reefs were no barrier, but the uppermost part of the basinward directed slope of the carbonate platform. The distribution of stromatoporoid - dominated facies on the reefs is considered.</ABSTRACT>

'anticlinorium de Philippeville.</TITLE>
10655 <SOURCE>Annales de la Societe geologique du Nord 06: 79-85.</SOURCE>
10656 <ABSTRACT>The revision of the Sautour-Surice geological map revealed
some important lateral facies variations in the Frasnian of the
Philippeville anticlinorium. Two kinds of lithological successions have
been observed, corresponding to the formations newly defined in the
Philippeville anticlinorium (proximal facies) and on the southern
border of the Dinant synclinorium (distal facies). The geographic
repartition of the two facies is schematically presented. A new section
(distal facies) is described from the Hermeton valley (SE of the
Philippeville anticlinorium). As a conclusion, the origin of the
coexistence of the two facies types in the Philippeville anticlinorium
is discussed.</ABSTRACT>

10667 <TITLE>An example of reef development in the Middle Devonian (Candas
Fm., Givetian) in the Cantabrian Mountains (NW Spain).</TITLE>
10668 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester
P. (ed.) Proceedings of the VI. International Symposium on Fossil
Cnidaria and Porifera, vol. 2]: 103-110.</SOURCE>
10669 <ABSTRACT>A well exposed section, showing three different types of reef
carbonate units of the Candas Formation (Givetian) close to the
locality of Coallaju (province of Asturias, NW Spain, Cantabrian
Mountains), is described in detail. This formation consists of
limestones with argillaceous intercalations, marls and dark lutites.
These materials were deposited probably on a carbonate ramp with gentle
slope and irregular bottom. The first type with a biohermal aspect,
lithologically consists of limestones; its basal part overlies a
crinoid-brachiopod packstone. This bioherm, small in size, is mainly
built by tabular and hemispherical stromatoporoids and alveolitids
associated with smaller numbers of other organisms. The second type,
developed in argillaceous limestones, consists of a series of
biostromes formed by branching coral bafflestones (Thamnopora and
Smithiphyllum); within them an outstanding massive rugose coral
framestone (Argutastrea and Endophyllum) occurs. The third type,
biohermal in shape, is made up of massive grey limestones forming a
sharp relief on the terrain. Recrystallization of the builders and bad
exposure conditions prevented the study of the faunal content and,
therefore the analysis of this reefal unit. A detailed analysis is made
of the faunal composition, with special emphasis on the more common
fossil assemblages in these reef units. Finally, on the basis of faunal
and sedimentological data, a paleoecological interpretation is given.

- 10682 <ABSTRACT>Maps of individual buildup facies from the prospected ME Moravia oil field (100 x 25 km) are presented. Considering reshuffle of the Devonian lithostrata and of the stratigraphic columns for the individual tectonic belts, the basinal analysis is suggested, including an expanded tentative model of the Frasnian configurations. Besides the global climatic factors, the Emsian-Frasnian tectonic changes within the Laurussian shelf favoured the giant growth of the Givetian-Frasnian buildups.</ABSTRACT>

- 10695 <ABSTRACT>In the Paleozoic series of the Cantabrian Mountains, reefal carbonates occur first in the Devonian. In this period, a sequence of terrigenous and carbonate sediments with varied reefal development was deposited on a shallow marine platform. The most widespread reef facies occurred at the end of the Lower Devonian and in the Middle-Upper Devonian, coinciding with the deposition of the Moniello-Santa Lucia (Upper Emsian-Lower Eifelian) and Candas-Portilla (Givetian, locally Givetian-Lower Frasnian) Formations. In addition, some reefal episodes of minor importance were developed at slightly older and younger stratigraphic levels (Rafieces-La Vid Group and Pineres-Nocedo Formation, respectively). Carbonate facies in the Moniello-Santa Lucia Formation are arranged in parallel strips with sublittoral facies towards the west and southwest and shallower water, lagoonal and peritidal deposits towards the north and east. In the more distal facies, biostromes and bioherms occur. The bioherms, developed in massive limestones, consist of large stromatoporoid and tabulate coral framestones with numerous encrusting growths, the stromatoporoids being the dominant reef building organisms. The biostromes are developed in the more argillaceous limestones. Seven types have been distinguished on the basis of their faunal composition and the morphology of the constituting organisms (mainly stromatoporoids and corals). The study, mainly paleontological, of the reef structures present in the Candas-Portilla Formation suggests a sedimentation model corresponding to a carbonate ramp, with a gentle slope towards the south and west and a slightly irregular bottom, where biostromes and occasional bioherms were developed. Bioherms are basically built by tabulate and massive rugose corals, although stromatoporoids more rarely occur as one of the main reef builders. Six types are differentiated on the basis of faunal composition and the morphology of the principal reef building organisms. On the basis of the faunal content and sedimentological observations of these reefs, different paleoecological interpretations are made of the most favourable environmental conditions for their development.</ABSTRACT>

10733 <SOURCE>Geol. Palaont. Westf. 26: 77-106. [in German, with English summary].</SOURCE>
10734 <ABSTRACT>The carbonate sequence (600 m thickness) of the Asbeck quarry (Hoennetal, Rhenish massif) belongs to the Devonian Hagen - Iserlohn - Balve reef complex and consists of reef core, lagoonal, and inter-/supratidal deposits. The succession of the six principal facies types allows recognition of three orders of cycles. 1st order cycles subdivide the section into five formations. Complete 2nd order (decameter) and 3rd order (1-3 meters) cycles exhibit a subtidal (reef core > sublagoonal > lagoonal) > intertidal > supratidal succession. They represent the regressive pulses of relative sea-level changes following rapid nondepositional transgressions. These can eventually be explained by abrupt subsiding movements of the Lenne inversion structure at the northeast margin of which the depositional area was situated. During each of the following tectonically quiet phases, seaward shoreline progradation was combined with a progressive infilling of the lagoon behind the reef belt, finally resulting in tidal influences and subaerial exposure. Due to the biostratigraphical data, correlations with eustatic sea-level curves are impossible.</ABSTRACT>

10746 <SOURCE>Revista Espanola de Paleontologia 9, 1: 29-36.</SOURCE>
10747 <ABSTRACT>In the Asturian-Leonese area of the Cantabrian Zone, an important reef development took place during the Devonian. The most widely represented reef structures originated at the end of the Early Devonian (late Emsian) and during the Middle Devonian (Givetian), coinciding, respectively, with the deposition of the Moniello-Santa Lucia and Candas-Portilla limestone formations. Minor reef episodes occurred also at older stratigraphic level (Rafleces-La Vid Group, late Emsian) as well as younger ones (Pifleres-Nocedo Formation, Frasnian). Most frequently, the reef units correspond to biostromes. However, bioherms also occur. In the Moniello-Santa Lucia Formations, stromatoporoids are generally the main reef-building organisms; in all other formations, the most common reef builders are rugose and tabulate corals. A palaeoecological analysis has been combined with results of earlier sedimentological work in order to reach conclusions regarding the most favourable conditions for reef development as well as the role played by the different reef building organisms.</ABSTRACT>

10758 <TITLE>Affinites nord-americaines de taxons devoniens (Givetien-Frasnien) du Boulonnais, Nord de la France. Migrations et diachronismes.</TITLE>
10759 <SOURCE>Bulletin de la Societe geologique de France 165, 4: 291-306.</SOURCE>
10760 <ABSTRACT>Recent studies (Brice 1988a) show that most of the Devonian taxa in Boulonnais have Old World Realm affinities. Nevertheless about 5% of the benthic taxa in Tabulate Auloporida, brachiopods, crinoids, ostracods are very similar to eastern Americas Realm taxa and their occurrence, with references to the conodont zonation, comes later in Boulonnais than in North America. The distribution of these benthic taxa in different Givetian-Frasnian palaeogeographical reconstructions shows large discontinuities: we must assume some trans-oceanic migrations from North America to western Europe. To be successful, these trans-oceanic migrations need the combination of many different factors, including both biotic and non biotic ones. The uncertainties of the result can explain the observed diachronisms.</ABSTRACT>

10797 <TITLE>Middle Devonian biogeography of closing South Laurussia-North Gondwana Variscides: Examples from the Bohemian Massif (Czech Republic), with emphasis on Horni Benesov.</TITLE>
10798 <SOURCE>Palaios 10: 221-239.</SOURCE>
10799 <ABSTRACT>Middle Devonian (Eifelian and early Givetian) brachiopod and coral faunas of the Bohemian Prague Basin and Moravian Celechovice and Horni Benesov regions, Czech Republic, are essentially dissimilar to each other, although the trilobites of the Prague Basin and Horni Benesov show some similarity. Apart from their mutually low similarity, expressed by the Otsuka Coefficient, each of the Czech faunas is comparable to faunas of other regions, particularly to the Rhenish Slate and/or Harz mountains. Although some of the differences among the respective Bohemian Massif faunas are mostly facies-controlled, they also appear to be a consequence of dispersal patterns of larvae by marine surface currents. Shallow water benthic communities show that oceanic circulation at this time could have been restricted by land masses, and perhaps by quite disjunct regions that have since been juxtaposed. As the Bohemian massif approached southern Laurussia, a progressive exchange of faunas from both shelves took place. It appears, moreover, that from late Emsian to the present there was not a significant separation between North Africa and Europe.</ABSTRACT>

10810 <TITLE>Current and wind induced facies patterns in a Devonian atoll: Iberg Reef, Harz Mts., Germany.</TITLE>
10811 <SOURCE>Palaios 10, 2: 180-189.</SOURCE>
10812 <ABSTRACT>The Middle to Upper Devonian Iberg Reef was an oceanic atoll within the Rhenish Trough of the Variscan Geosyncline. It existed for at least 15 million years before it was drowned shortly before the turn of the Frasnian-Famennian. The spatial distribution of facies and early diagenetic features within these Frasnian reef limestones confirms the reefs paleogeographical location between the equator and 30° south. The southeastern, windward side of the atoll was dominated by massive stromatoporoids and bulbous corals as well as by encrusting and dendroid stromatoporoids. Reef-builders were rarely preserved in situ. Several generations of early fibrous cement form thick isopachous crusts on the limestone components, confirming early lithification. On the northwestern, leeward side, platy and branching stromatoporoids and corals predominated. They were mostly preserved in growth position. Fine-grained sediment forms a large portion of the limestone matrix. A leeward lagoon entrance was marked by large thickets of branching rugose corals and a mixture of back reef and fore reef faunal elements in the northwesternmost lagoonal limestones. A chain of stromatoporoid gravel cays formed inside the lagoon due to wave-refraction on the southern reef front.</ABSTRACT>

10824 <SOURCE>Neues Jahrbuch fuer Geologie und Palaeontologie, Monatshefte 1995, 5: 279-294.</SOURCE>
10825 <ABSTRACT>Facies and organism guilds (constructor, binder, baffler, dweller, destroyer) were quantitatively investigated in 497 evenly spaced samples in the upper part (30-160m) of the borehole "Iberg 1 " that penetrates 420m of Devonian reef limestones. The investigated section encompasses transitans, punctata, hassi and parts of falsiovalis and jamieae conodont zones of the Frasnian which cover a time span of 2-2.5 Ma. The majority (72%) of the limestones are rudstones; 19% of the limestones are grainstones; only 9% of the core are stromatoporoid and coral boundstones. The first component obtained by principal component analysis of the time series can be assigned to the process of reef construction. A Fourier spectral analysis revealed cyclic fluctuations of the first component, although cyclic changes are not visible in the core. The relationships of the cycles to orbital cycles and sea level fluctuations are discussed.</ABSTRACT>

10836 <TITLE>The Middle and Upper Devonian Reef-Complexes of Belgium.</TITLE>
10837 <SOURCE>Petrol. Geol. of Taiwan 8: 119-173.</SOURCE>
10838 <ABSTRACT>The Middle and Upper Devonian (Frasnian) reef-complexes are well exposed in the Dinant, Namur and Vesdre basins. The Middle and Upper Devonian stratigraphy and sedimentation in Belgium are briefly described. Early work interpreted the red coloured Phillipsaeraea facies as a time stratigraphic lithologic unit. However, from detailed field examination, detailed paleoecologic study and rugose corals study, this red coloured Phillipsaeraea facies is in fact time-transgressive. The most common and important fossil organisms found in the reef complexes are illustrated. Their distribution in the reef complexes and their ecological significance are discussed. The variations in sedimentary facies within the reef complexes are described and related to factors which influenced the changes. The depositional history is outlined and divided into four phases: a. the transgressive phase, b. the relatively stable phase, c. the regressive phase and d. the transitional phase. Finally, the terminology and classification for the various carbonate depositional environments of the different facies are suggested.</ABSTRACT>

10862 <TITLE>Paleoecology of Middle Devonian and Frasnian in Belgium.</TITLE>
10863 <SOURCE>[journal?] Symp. Namur 1974, publication 12.</SOURCE>
10864 <ABSTRACT>The paleogeographic patterns of the Middle Devonian and the Frasnian are first reconstructed and illustrated. Generally, the Couvinian and the lowermost Givetian beds become more and more sandy towards the north and east. This indicates clearly that the sediments came from the direction of the Brabant and Stavelot massifs. Evidence furnished by the facies distribution demonstrated the existence of the Rocroi and the Stavelot islands. In Middle Couvinian time, the continental regions were in the north. The Rocroi island was a very low almost featureless area, but the Stavelot island was still high land. It was only at Middle Givetian time that the Stavelot island became a

nearly featureless region, and the Rocroi island subsided with the transgression of G₂ and disappeared definitively during early Middle Givetian time. The Upper Givetian beds represent a regressive phase. The G₃ is a period of relative stability during the regressive phase. The paleogeographic pattern of Frasnian time is quite different from those of the Middle Devonian. Consequently, the development of the reefs and the sedimentary facies distribution were in a manner totally different. * Then the most common and important fossil growth forms are described. Their ecological significance is discussed in detail. In the case of Lion reef, Stromatoporoids and Corals were the principal frame builders in the Devonian reefs. Algae were subordinate. In the case of Neuville reef, Algae were the principal reef builders. * The reefs grew in various environments with correspondingly different associations of reef-building organisms. * Finally the factors which controlled the vertical and lateral distribution of the various facies are discussed. Several major lithic-faunal associations are recognized during the different phases in the Middle Devonian and Frasnian rock sequence of Belgium. Five types of organic reefs can be distinguished in the Ardennes geosyncline. The reef development was mainly controlled by the paleo geographic pattern and the epirogenic movements.</ABSTRACT>

10876 <SOURCE>Bulletin Geol. Survey Prague 49, 4: 193-200.</SOURCE>

10877 <ABSTRACT>Paleozoic sediments in the Nitkovic-2 borehole are represented by the limestones of upper Middle Devonian age - the Givetian and of lower Upper Devonian age - the Frasnian. They have been evidenced paleontologically at a depth of 868 to 1707m. Their stratigraphy has been determined on the basis of abundant stromatoporoid fauna and tabulate corals. For precision of the stratigraphic conclusions the foraminiferal fauna has been studied.</ABSTRACT>

10994 <ABSTRACT>10 types of reefs are described. These are barrier reef (R1), patch reef (R2), bioherm complexes (R3A, R3B), biostromes (R4I, R4II, R4III, R4IV), and mud mounds (R5A, R5B). Most of them (R1, R2, R3 and R4) have developed during relatively stable phases (tectonically calm periods). Other reefs (R5A, R5B) of different types developed during the transgressive phases. * The growth forms of most common and

- important reef building organisms are described. Their ecological significance is discussed. The environmental distribution of the reef building organisms and their ecological adaptations in the different facies are shown.

11044 <TITLE>Cyklicka sedimentace v devonských karbonátech Macoskenko souvrstvi. [cyclic sedimentation of the Devonian Macocha carbonates; in Czech, with English summary]</TITLE>
11045 <SOURCE>Zemni plyn a nafta 28: 1-14.</SOURCE>
11046 <ABSTRACT>(1) At the cumulation of the facial and stratigraphical sections trough the Devonian reef complex of Macocha - formation

defined by Zúkalová - Chlupáč (1982) a cyclic pattern of carbonate sedimentation has been observed. The cycles of various order have been documented. In the present paper four composite cycles of the greatest magnitude are defined. Starting from the base they are the Celechovice-cycle, the Byčí-cycle, the Ochoz-cycle, and the Mokra-cycle. (2) The range zone of the defined cycles are marked by clastic intercalations, break and erosion levels, laminite, breccia or limestone with many intraclasts, nodular textures, intensive dolomitization or occasionally by silification. The development of low magnitude and complex cycles of the greatest magnitude generally obtain the Kassiğ's phasis succession. Progressively, the dark micritic carbonate sediments go over the Amphipora limestones to predominantly light-grey biostromal and biohermal limestones. Succession may be modified by local factors, but ranges of major cycles are remarkably fast in all cases. (3) The cycles mentioned above are more restricted to some time-scale intervals than members which are used usually in mapping. Therefore, these cycles make possible to correlate borehole cores in inner structures of the Macocha Formation. Each of the cycles has particularly modified its lithological succession and biozone sequence, essential in low taxons at least, in context to development of the whole reef complex (see Hladil 1983). Application of cycles defined concerns the oil wells drilled in Bohemian massive slopes, in the South region. [original summary]

- 11072 <ABSTRACT>This study explores a genetic link between modern Atlantic coral mounds and ancient, sponge-rich carbonate mudmounds based on Ca-carbonate authigenesis driven by induced-and-supported organomineralization (ISOM). The potential for ISOM in Atlantic coral mounds is tracked by peak patterns of fluorescent dissolved organic matter (FDOM) present in pore waters down to 3 m of sediment depth (Gamma mound, Beta mound, Pen Duick escarpment, offshore Morocco). The modern coral-rich mound system, which by itself appears diverse and with a variety of controlling factors, maintains an excellent potential to drive ISOM and to share a crucial process of early diagenesis with Phanerozoic sponge rich carbonate mudmounds.</ABSTRACT>

- 11098 <ABSTRACT>The oldest reefal episode in the Cantabrian Zone (earliest Pragian) consists of small biostromal patch reefs, mainly built by corals and stromatoporoids, and developed on a storm-dominated ramp. Four outcrops provide the stratigraphic framework in which these reef facies developed, and these permitted an interpretation of their depositional setting in terms of a relatively distal or protected shelf. Six species of stromatoporoids are described: *Labechiella* sp. 1; *Labechiella* sp. 2; *Intexodictyon perplexum* Yavorsky, 1963; *Plectostroma salairicum* (Yavorsky, 1930); *Habrostroma centrotum* (Girty, 1995); and *Parallelostroma foveolatum* (Girty, 1995). 11110 <SOURCE>Bulletin of Geosciences 84: 75-106.</SOURCE>
11111 <ABSTRACT>The early middle Frasnian (Upper Devonian) punctata Zone interval of Moravia, Czech Republic, was chosen, because a pure limestone lacking an obvious siliciclastic component is present, and because the authors had access to voluminous surface and subsurface stratigraphic data. Research methodology included [quotations from abstract, p. 75]: "... biostratigraphy and facies analysis, magnetic susceptibility (MS), gamma-ray spectrometry (GRS), instrumental neutron activation analysis (INAA), and finally, separation and assessment of rare non-carbonate particles." ... "The most significant disturbance was found near the mid-punctata Zone level." They conclude that the exotic nature of the grains may be due to the Alamo Impact Event in Nevada, USA [see Au] 2010 & Au] et al. 2010], but feel that a single event does not explain all their findings.</ABSTRACT>

11122 <TITLE>The Odivelas Limestone: evidence for a Middle Devonian reef system in western Ossa-Morena Zone (Portugal).</TITLE>
11123 <SOURCE>Geologica Carpathica 60, 2: 121-137.</SOURCE>
11124 <ABSTRACT>The Odivelas Limestone constitutes one of the few records of Middle Devonian sedimentation in the western Ossa-Morena Zone. Although deformed and metamorphosed the limestones have an abundant fossil content which allows their positioning as late Eifelian/early Givetian in age and to relate the reef fauna with the typical Rhenish facies for the same time period. Magnetic susceptibility analysis was attempted and is in agreement with the biostratigraphy, but the limited extent of sections and the metamorphism precludes firm correlations. The field evidence, petrographic and geochemical analysis point to a close paleogeographical relation and dependence of the reef system on volcanic structures which are included in the Beja Igneous Complex. The age of part of the volcanic and sub-volcanic suite of this complex is thus constrained. [original abstract]</ABSTRACT>

- 11137 <ABSTRACT>The Devonian succession between the Guadiana and Guadalquivir valleys in the Obejo-Valsequillo Domain comprises more than 600m of shale and sandstone with some interbedded limestone and marl. The most complete reefal sequences of the region are exposed in the Guadamez-2 section, which is located on the western bank of the Guadamez River, near Zalamea de la Serena. It consists mainly of shale and calcareous shale in its lower part and shaly, skeletal and reefal limestone in its upper part. Conodont and brachiopod data indicate that this section spans the interval from the Lochkovian to at least the upper Emsian. Eight microfacies types have been identified in the calcareous facies: (A) brachiopod-echinoderm wackestone/packstone; (B1) echinoderm grainstone; (B2) echinoderm-bryozoan grainstone/packstone; (C) echinoderm packstone; (D) tabulate coral rudstone; (E) brachiopod wackestone/packstone; (F) brachiopod grainstone/packstone; and (G) stromatoporoid and tabulate coral boundstone/rudstone. Microfacies A, B1, C, E and F represent a sequence of environments from middle platform (A) to tidal flat (F), including shoals (B1) and shallow platform facies. Microfacies B2, D and G represent the development of patch-reefs superimposed on the shoals. [original abstract] </ABSTRACT>

- 11150 <ABSTRACT>A multitude of new finds permit a fundamental revision of the fossil contents of the Wiltz layers. For this purpose, approx. 5,700 proofs of finds were evaluated. Due to the numerous finds, the study will be published in several parts. It turns out that the species-diversity is very much greater than assumed to date. The presence of many of genera and species known from other sedimentation areas have now been proved for the Wiltz-layers in the Wiltz-basin and Daleiden synclinal Group. This publication includes plant fossils, *Rhaphidopora* sp. cf. *Rhaphidopora lonsdalei*, *Cornulites* sp. and *Pterygotoidea* fam., gen. et sp. indet. The trilobite *Leonaspis grafi* n.sp. is described. * Finally, the area examined can be defined as an extensive long-lived deposit region of a shallow water situation extending from close to and far from the coast of the Ardennes-Rhenish continental shelf with multifold faunistic correspondences to other regions in the Variscan sea during the upper Emsian. 11161 <TITLE>Basic information about the sedimentology and diagenesis of the Koneprusy Reef (Lower Devonian, Pragian, SW segment of the Central Barrandian Synform).</TITLE>
11162 <SOURCE>FCnP 24, 1: 26-41.</SOURCE>
11163 <ABSTRACT>The Koneprusy reef is a unique bioclastic complex of Pragian age that can be compared only with few places in the world (Carnic Alps, Ufimia Amphitheater of Urals, Rocky Mountains of Canada). This reef possess a long history of investigation. Rich paleontological material of the Koneprusy sites is deposited in prominent musea and universities of the world. There is only roughly estimated that 500 species have been already distinguished by variety of authors. Probable number of fossil organic species can be limited by 800. Uncovered complex is situated within the classic area used for the standard Devonian stratigraphical settings. Discernment of the diagenetical history can contribute also to the knowledge about the Variscan history of the Central Europe. [introduction to a short note; major part of the note is a list of publications, pertaining to the Koneprusy limestone]

11174 <TITLE>Les Formations du Frasnien de la Belgique.</TITLE>
11175 <SOURCE>Mem. Geol. Surv. Belgium 44: 126 pp., 60 figs.</SOURCE>
11176 <ABSTRACT>This memoir on the Frasnian formations of Belgium is the result of meetings and field trips of the National Subcommission on Devonian Stratigraphy. It was prepared in collaboration with geologists involved in the new mapping programm of Wallonia at scale 1/25 000. Seventeen formations are described. Six of them (Aisemont, Barvaux, Bovesse, Franc-waret, Matagne en Rhisnes) are well known from literature. The eleven others (Grands Breux, Huccorgne, Lambermont, Lustin, Moulin Lienaux, Neuville, Philippeville, Pont de la Folle, Presles and Valisettes) were introduced during the last twenty five years. All these formations are revised and presented in files giving a brief historical account, location of the reference sections, lithology, limits and thickness at the stratotype or the reference sections, lateral variations, ages and eventual uses. Furthermore, each formation is documented by the location of the outcrops on a portion of the relevant topographic map (scale 1/10 000) and by a cross-section or a stratigraphic log of the stratotype or other reference sections. Lastly, the tables in the opening section provide information on the historical subdivisions of the Frasnian in Belgium, the stratigraphic correlation between the Frasnian formations from different structural units recognized in this work and the stratigraphic distribution of the taxa of the fossil groups cited in the text. 11213 <TITLE>Late Devonian - Early Carboniferous deep-water coral assemblages and sedimentation on a Devonian seamount: Iberg Reef, Harz Mts., Germany.</TITLE>
11214 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 123, 1-4: 297-322.</SOURCE>
11215 <ABSTRACT>Growth of the Middle Late Devonian Iberg Reef, a small atoll in the Variscan Geosyncline of central Europe, ceased towards the end of the Frasnian. During the Famennian and Dinantian, the reef continuously subsided relative to sea level. In the latest Dinantian the reef was covered by clastics. Five deep-water organism assemblages colonized the Famennian-Dinantian seamount successively. They are well comparable to recent organism communities on deepwater coral banks. In the Famennian, abundant crinoids and ancillary rugose corals and brachiopods colonized the reef top. During the Late Tournaisian, a coral-crinoid assemblage established on the reef. It developed into a varied fauna of corals, crinoids, trilobites, brachiopods, bivalves, gastropods, and goniatites in the Early and Middle Visean. The Late Visean assemblage was dominated by goniatites and pseudoplanktonic bivalves. In the latest Visean, a monospecific brachiopod fauna and small microbial buildups thrived in extreme environmental conditions on the reef top. The skeletal debris of the organisms was eroded post-mortem and only accumulated in current-protected depressions of the reef surface, along with carbonate mud. Local depressions include hollows on the reef top, neptunian dikes, and pore space of a breccia that formed due to intensive shattering of the reef top during nearby volcanic activity. During most of the Famennian and Tournaisian, there is a hiatus caused by non-deposition. Only reworked Famennian and Tournaisian conodonts recovered from Upper Tournaisian-Middle Visean limestones give evidence of marine conditions on top of the reef. The sedimentary environment on the drowned atoll compares well to that on

recent guyots, including hiatuses, slow and patchy sedimentation, erosion and redeposition. Both the aftermath of the Frasnian / Famennian extinction that drastically reduced metazoan reef builders and a trend towards lower temperatures in the Famennian and Dinantian are believed to have produced the reestablishment of a shallow water reef on the drowning Devonian atoll.

- 11278 <TITLE>Late Devonian and Early Carboniferous Rugosa from Western Pomerania, northern Poland.</TITLE>
- 11279 <SOURCE>Acta Geologica Polonica 55, 4: 393-443.</SOURCE>
- 11280 <ABSTRACT>The taxonomic description of the Late Devonian and Early Carboniferous Rugosa from the boundary area of the Precambrian East European Craton and the Palaeozoic platform of Central Europe is presented. Palaeontological analysis and the stratigraphical distribution of the corals in Western Pomerania enabled recognition of several faunistic events, which reflect evolutionary trends in rugose corals. The pre-crisis Frasnian coral fauna, dominated by colonial forms both massive [*Disphyllia laxa* (Gürich, 1896), *Hexagonaria hexagona kowalae* Wrzosek, 1992, ?*Frechastrea*] and branching [*Disphyllum kweihsiense* Yoh, 1937, *Peneckiella ?fascicularis* (Soshkina, 1952), *Thamnophyllum monozonatum* (Soshkina, 1939), *Peneckiella szulczewskii* Rózkowska, 1979], developed on the carbonate platform extending along the edge of the East European Craton. The similarity of these faunas to Rugosa faunas from southern Poland is significant. The coral fauna was reduced significantly after the Kellwasser crisis. Colonial corals disappeared altogether and solitary dissepimented forms were markedly reduced. The subsequent Late Famennian radiation caused a significant quantitative and qualitative differentiation of the coral faunas. In addition to the well-known ?*Cyathaxonia* fauna, warm and shallow-water solitary corals appeared in the latest Famennian. The stratigraphically important taxa of the latest Famennian include: *Campophyllum* Milne-Edwards ?38; Haime, 1850, ?*Palaeosmia* aquisgranense (Frech, 1885), *Bounophyllum pomeranicum* sp.nov. and *Guerichiphyllum kowalense* Rózkowska, 1969. The latest Famennian regression caused subdivision of the Pomeranian area into at least two sedimentary basins, separated by shallows, with peculiar ecological conditions, and the appearance of numerous endemic taxa. This regressive interval contains, however, numerous levels yielding less restricted faunas, which suggest the intermittent appearance of more open-sea conditions.</ABSTRACT>

11317 <TITLE>Upper Devonian and Mississippian foraminiferal and rugose coral zonations of Belgium and northern France: a tool for Eurasian correlations.</TITLE>

11318 <SOURCE>Geological Magazine 143, 6: 829-857.</SOURCE>

11319 <ABSTRACT>The radiation of early Carboniferous foraminifers and rugose corals following the Devonian-Carboniferous crisis offers the best tool for high-resolution correlations in the Mississippian, together with the conodonts in the Tournaisian, notable in the Namur-Dinant Basin. However, some of the guides are facies-controlled and an integrated approach combining biostratigraphy, sedimentology and sequence stratigraphy is critical to identify delayed entries, potential stratigraphic gaps and to avoid diachronous correlations. The main difficulty is in correlating shallow and deeper water facies at any given time. In existing zonations, the Viséan part of the scheme is always more detailed, reflecting the widespread development of shallow-water platforms in the early Viséan which created conditions more suitable for foraminifers and rugose corals over larger areas. In contrast, the Tournaisian zones, less well documented, reflect unfavourable environmental conditions in the lower ramp (Dinant Sedimentation Area) and pervasive dolomitization of the inner ramp

(Condroz and Namur Sedimentation Area). Recent progress in understanding the Belgian early Carboniferous sequence stratigraphy and lithostratigraphy, and revision of the biostratigraphy of the key sections, strongly modify former biostratigraphic interpretations. Improvements mainly concern the latest Devonian, the late Tournaisian and the early Viséan. The late Devonian and the Tournaisian are equated with foraminifer zones DFZ1 to DFZ8 and MFZ1 to MFZ8 respectively. The Viséan correlates with zones MFZ9 to MFZ14. Zone MFZ15 straddles the Viséan- Namurian boundary and Zone MFZ16 is the youngest Mississippian zone. The rugose corals allow the recognition of the zones, RC0 to RC9, covering the Strunian (late Famennian) to Serpukhovian interval. Discrepancies with former zonations are discussed. The Moliniacian Stage is emended to restore the coincidence between the base and that of the Viséan.</ABSTRACT>

11331 <SOURCE>Courier Forschungsinstitut Senckenberg 100: 129-138.</SOURCE>

11332 <ABSTRACT>Preliminary description of a small coral fauna from the Devonian Carboniferous boundary section at La Serre, near Cabrieres, Hérault (selected as Global Boundary Stratotype to be submitted to the International Commission of Stratigraphy, Washington 1989). * This faunule consists of small solitary rugose corals, with tabulates and heterocorals (Sutherlandia, Heterophyllia) partly related to the " Cyathaxonia fauna" from the cephalopod facies of northern Europe, particularly the Holy Cross Mountains. Succeeding the Famennian metriophyllids of the basal unit (upper Palmatolepis expansa Zone) and after an interval of beds nearly devoid of corals, an obvious change coincides apparently with the boundary as defined by conodonts. It is characterized by the appearance of Carboniferous genera with dominant plerophyllids and some forms indicative of the Lowermost Tournaisian. The very beginning of this Carboniferous fauna occurs at the base of the Siphonodella sulcata Zone. * [Listed are] 11 genera, [with] 13 species of which most are new and provisionally described under open nomenclature.</ABSTRACT>

11369 <TITLE>Tabulata and Chaetetida from the Devonian and Carboniferous of Southern Poland.</TITLE>
11370 <SOURCE>Palaeontologia Polonica 35: 125 pp., 21 figs, 27 pls.</SOURCE>
11371 <ABSTRACT>The results of studies on Tabulata and Chaetetida from the Givetian, Frasnian and Visean of the Cracow-Silesian Upland (Cracow Region) and from the Visean of south-western part of the Holy Cross Mountains (Galezice) are presented. Forty-one species of Tabulata (orders: Favositida, Syringoporida, Auloporida) including eighteen new species, and six species of Chaetetida (family Chaetetidae) including three new species are described. Following new species are designated: Squameofavosites megasquamatus sp.n., S. (Dictyofavosites) pachyfavositoides sp.n., Emmonsia czarnieckii sp.n., Michelinia aseptata sp.n., Palaeacis orlei sp.n., Thamnopora striatoporoides sp.n., Alveolitella rarispinosa sp.n., Crassialveolites polonicus sp.n., Natalophyllum dubiensis sp.n., Tyrganolites frasnianus sp.n., Syringopora sinusoidea sp.n., S. subreticulata sp.n., S. tenuithecata sp.n., S. pachysiphonata sp.n., Multithecopora polonica sp.n., M. spinosa sp.n., Syringoporella longituba sp.n., Sinopora polonica sp.n., Cyclochaetetes tuberculatus sp.n., Chaetetella (Chaetetiporella) heterozoa sp.n., Ch. (Chaetetiporella) rotiformis sp.n. * It has been stated here that only two types of asexual reproduction occur in Tabulata: (1) intracalicular budding, and (2) longitudinal division. Three variants of intracalicular budding have been studied in detail: (a) intravisceral budding realized by wall outgrowths or invaginations in the wall of parent calices; (b) mural budding, and (c) extravisceral budding. The comparison of described Tabulata and Chaetetida assemblages with contemporaneous assemblages of Europe and Asia indicates that: (1) the Givetian assemblage of Debnik anticline is mixed and rather poor in species; (2) the Frasnian assemblage of Debnik anticline displays great similarity to West-European tabulate corals, (3) the Visean assemblage from the Holy Cross Mountains (Galezice), except of a few local components, is close to the west-European assemblages. The assemblages of Chaetetida from the Visean of the Holy Cross Mountains (Galezice) have many species common with East-European

- assemblages (Moscow Basin). [original abstract] </ABSTRACT>

- 11383 <SOURCE>Géologie de la France 2006, 1-2: 21-27.</SOURCE>
- 11384 <ABSTRACT>The Ardenne Massif is part of a complex of Palaeozoic outcrops between the Channel in the west and the Rhine river and beyond in the east. It has registered both the Caledonian and the Hercynian orogenies. Originally part of a terrane located north of the Gondwana supercontinent (Avalonia), it became an element of the southern margin of the Old Red Sandstone Continent (ORSC, also called Euramerica, Laureuropa, or Laurussia) in the Devonian and Carboniferous, when it suffered the effects of the Hercynian orogeny by collision of the ORSC and Gondwana. These global tectonic events, linked to climatic changes due to continental drift, had profound consequences on the living organisms of the Ardenne Massif. Here we focus on some aspects of a series of animal groups of western Ardenne, being elements of either the benthos (brachiopods, trilobites), or the reefal environments (tabulate corals, stromatopores), or the nekton (vertebrates, including the first tetrapods). When vertebrates ("fishes") and brachiopods were quite abundant as early as the base of the Devonian, mostly in siliciclastic facies, reefal organisms appear only in the Emsian, and become abundant in the Eifelian, with the development of a carbonate platform. Reefs or reef-like buildings occur up to the Early Carboniferous, where new fish assemblages are known. Trilobites occur often with brachiopod-bearing communities. The trilobite-rich locality of the "Mur des Douaniers", at the former French/Belgian boundary, is an example of an early Eifelian Fossil-Lagerstätte, now protected as a Nature Reserve. - 11397 <ABSTRACT>Reef development in the Famennian and Carboniferous successions of Belgium is more common than previously thought, and 10 broad time intervals of reef development can be differentiated. Reef formation is due to a variety of reef fabrics. Microbial communities are important for most reef frameworks, and often crucial for formation and stabilization of frameworks. Larger skeletal frameworks are rare.

However, the interaction of skeletal bioconstructors and microbial communities is common, and results in successful reef building. However, microbial communities are still the backbone of these reefs. The majority of reefs are small, and a significant number formed in environments of restricted marine facies. Large reefs developed only in the late Tournaisian and late Viséan. Their initiation and formation was controlled by the geometry of the shelf. Three hierarchical levels, discussed below under the headings palaeobiology, local environment, and regional and global environment, controlled reef formation. Important limiting factors were relative water depth, sea-level oscillations, climate, shelf geometry and the needs of the individual bioconstructor. In general, Belgian reef diversity reflects the global picture, but significant differences can be recognized in the different time slices. In particular, the abundance of middle Viséan reefs is a unique feature. The onset of the Variscian orogeny terminated all reef development in Belgium, and reefs younger than late Viséan are unknown.

11409 <SOURCE>Geol. Jb. A 129: 5-193.</SOURCE>

11410 <ABSTRACT>Growth of the Devonian (Middle to Upper) atoll of Iberg and Winterberg in the Harz Mts. ceased towards the end of the Frasnian. After the death of the last reef-building organisms, from Famennian to Gattendorfia Stage (cul), the reef persisted in the shallow water environment. During this time there is a hiatus caused by nondeposition. Only conodonts accumulated in hollows on the old reef. Reworked conodonts in Dinantian limestones provide evidence for marine conditions during the Famennian and the time of the Gattendorfia Stage. An exception are neptunian dikes that opened during the Upper marginifera Zone (do II/III) and were filled with crinoidal limestones. [first fragment of extensive summary]</ABSTRACT>

11422 <SOURCE>Greifswalder Geowissenschaftliche Beiträge 6: 347-365; Greifswald.</SOURCE>

11423 <ABSTRACT>The borehole Pudagla 1/86 on the isle of Usedom is the most northwesterly situated deep well in Germany. This borehole is 7550m deep. Below younger deposits the Lower Carboniferous, the Upper Devonian and partially the Middle Devonian were pierced. The authors examined biostratigraphically the Lower Carboniferous and the Upper Devonian beds. The most important results of this work are published in this paper. The work involves investigations concerning foraminifers,

- tentacilites and calcareous algae. Contrary to the isle of Rügen, the Lower Carboniferous contains volcanic rocks. The age of volcanic activity is determinable by fossils biostratigraphically. [original abstract]

11487 <SOURCE>Korally srednego Karbona zapadnogo sklona Urala; Nauka, Moskva: 224 pp., 43 figs, 3 tab., 23 pls.</SOURCE>
11488 <ABSTRACT>The book deals with all Middle Carboniferous tabulate and rugose corals known from the western slope of the Ural mountains. The first chapter gives a brief history of investigation on Middle Carboniferous corals. The second chapter contains descriptions of the stratigraphical units and their position, together with the fossil assemblages (corals and others). Theme of the third chapter is the correlation of the coral faunas and also the stratigraphy with those from other regions of the USSR, Western Europe and China. The main part of the book contains descriptions of 65 species and subspecies. 43 are new ones together with one subgenus - Lophophyllum (Koninckophylloides) n.sub.-gen. [described are: Chaetetes, Multithecopora, Cladochonus, Amplexus, Hapsiphyllum, "Zaphrentis", Caninia, Pseudotimania, Bothrophyllum, Campophyllum, Lophophyllidium, Lophophyllum (Lophophyllum), L. (Koninckophyllum), L. (Arachnolasma), L. (Pischerina), Lithostrotion, Orionastraea, Lithostrotionella, Lytvophyllum, Corwenia, Kionophyllum, Cravenia, Dibunophyllum; new subgenus: Lophophyllum (Koninckophylloides), with type species L. (K.) uralicum from the Middle Carboniferous of Bashkiria: p. 132, pl. 18: 2, 3]</ABSTRACT>

11551 <TITLE>The Upper Viséan coral bearing horizons of Royseux - the development of an unusual facies in Belgian Early Carboniferous.</TITLE>
11552 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the

- 8th International Symposium on Fossil Cnidaria and Porifera]: 86-95.
</SOURCE>
- 11553 <ABSTRACT>Two coral horizons in the Anhée Formation (Upper Visean) of Roseux are an unusual development for the Early Carboniferous of Belgium. The first horizon is found at the base, the second one at the top of the sequence +2. Only this sequence reflects a deepening-upward and a shallowing-upward trend, in contrast to the other sequences, which display a shallowing-upward trend only. Three evolutionary stages (stabilization, colonization, diversification) can be recognised in a biostrome forming the first coral horizon. A second biostrome principally constructed by Siphonodendron junceum forms the base of the complex second coral-horizon. This horizon is followed by pebbly rudstones and a coral thicket of Siphonodendron martini. Changes in the coral-fauna are connected with changes in the paleoenvironment, caused by sea level fluctuations and/or changes in the geometry of the seafloor. Corals of the genus Siphonodendron seem to have high ecological variability and distribution.</ABSTRACT>

- 11592 <ABSTRACT>In Belgium and adjacent areas, 38 biozones (including 43 subzones) can be distinguished in the interval ranging from the base of the Strunian to the top of Yeadonian. These are illustrated on three range charts. The subdivisions of the Dinantian are based essentially on conodonts, foraminifera and rugose corals. The Namurian stages (with the exception of the Pendleian) are recognized by means of goniatites and, from some limestone layers, of conodonts and foraminifera. The most of the biozones can be traced in western Europe and a large number of them along the Eurasian province. The conodonts, foraminifera and rugose corals which can be used for widespread correlations in the Lower Carboniferous have been checked.</ABSTRACT>

- 11631 <ABSTRACT>The Los Santos de Maimona Basin comprises more than 1000 m of Upper Visean rocks of varying lithology, divided into 8 lithostratigraphic units, from 0 to 7. Clastic sediments and volcanic rocks are dominant in units 0, 2, 5 and 7; carbonate sediments are common in units 1, 3, 4 and 6, and scarce in units 2 and 5. The varied environments of the different units provide an excellent way of comparing the coral distribution effect of ecological factors. In addition, the order of appearance of lithostrotionids, similar to that in Belgium, allows precise dating of the units containing colonial Rugosa. Corals are common in all carbonate units. Unit 1 yielded abundant fasciculate (both rugose and tabulate), and solitary corals, mainly dissepimented. Massive and fasciculate colonial corals are common in Unit 3, in which solitary corals are scarce. In Units 4-6 solitary undissepimented corals are dominant; some colonial corals also occur.</ABSTRACT>

- 11644 <ABSTRACT>Drewer (Rhenish Massif) and Saalfeld (Thuringian Massif) are the two most important German localities yielding corals of top Upper Famennian and basal Lower Tournaisian times, between the Hangenberg and the crenulata events (Upper praesulcata Zone to sandbergi Zone). The Anthozoan community of Drewer is reviewed (both Tabulata and Rugosa), and the following taxa are described: Cyathaxonia n.sp. A, n.gen. n.sp. (aff. Kabakovitchiella), Hebukophyllum priscum (Muenster 1840), Drewerelasma schindewolfi Weyer 1973, Pentaphyllum walliseri n.sp., Commutia schmidti n.sp., Commutia longiseptata Fedorowski 1973.</ABSTRACT>

11824 <TITLE>Heterocorallia from the Early Carboniferous of the Moldanubian Southern Vosges Mountains (Alsace, France). </TITLE>
11825 <SOURCE>Neues Jahrbuch fuer Geologie und Palaeontologie, Abhandlungen 224, 2: 223-254. </SOURCE>

- 11826 <ABSTRACT>within the Mid European Variscian Belt, Heterocorallia have been described from the Rhenohercynian, the Saxothuringian and Upper Austro-Alpine. A section from the Early Carboniferous of the Moldanubian Southern Vosges Mountains has yielded Heterocorallia, which are here described for the first time: Hexaphyllia sp. 1, Hexaphyllia sp. 2, Heterophyllia sp. and Heterophyllia aff. ornata M'Coy, 1849. Their occurrence in calciblastic turbidites is an evidence for a Moldanubian carbonate platform. The fragile character of heterocoral polypars in general might be an indication for low water energy environments within the platform. A comparison from Rhenohercynian, Saxothuringian and Moldanubian Heterocorallia results in good correspondence concerning occurring taxa. Together with smaller benthic forminifera it is possible to date the Heterocorallia bearing sediments from the Southern Vosges as Arundian (Viséan).</ABSTRACT>

- 11839 <ABSTRACT>Heterocorals found in several sections of the Carboniferous from Los Santos de Maimona area yield always at the same stratigraphic level. The abundant specimens from Sierra Cabrera outcrops correspond to a population with a high morphological variability. Fortyfour percent of the specimens have more than 6 septa (7-9) and consequently they cannot be included definitively into Hexaphyllia. However, most of the characteristics of the specimens are similar to Hexaphyllia mirabilis. The validity of this genus is questionable.</ABSTRACT>

11930 <ABSTRACT>The rugose coral Delepinella anastomosa nov. gen., nov. sp., is described from the Upper Tournaisian limestones of the Laval Synclinorium (Armorican Massif - France). Delepinella shows many morphological features in common with genera of the family Aulophyllidae. Belonging to the "Caniniid-Clisiophyllid" fauna (D. Hill 1938), D. anastomosa probably indicates a shallow water environment. A part of the Tournaisian corals fauna from the Laval Synclinorium seems to be endemic.</ABSTRACT>

11943 <ABSTRACT>Detailed studies on Rugose Corals of the Carboniferous from Cantabrian Mountains is making evident these fossils can be very useful in biostratigraphy. Several coral associations characterising some steps from Serpukhovian, Upper Bashkirian-Lower Vereyan, Upper Kashirian-Lower Podolskian, Upper Podolskian and Kasimovian. Further, several species can be considered characteristic because their broad geographic and restricted stratigraphic distributions. These species must be the basis of the biozonation with corals of the Carboniferous from Cantabrian Mountains.</ABSTRACT>

11955 <SOURCE>Palaeontographica A190: 1-81.</SOURCE>
11956 <ABSTRACT>(Rugose corals of the shallow-water-facies in the Upper Carboniferous of the Cantabrian Mountains (N. Spain)On several

expeditions (1975-78) to the Carboniferous in the Cantabrian Mountains, the author collected many rugose corals of the shallow-water-facies (corals with dissepiments). This collection has been completed by material from our team F 10 of the [Sonderforschungsbereich 53](#). In the palaeontological part 48 species and subspecies of 20 genera are described. Almost half of the forms belong to new species. Altogether one genus and 22 species and subspecies have been established: Kullmannophyllum n.gen. with the typespecies K. triolloense n.sp. and species and subspecies of the following genera. Namurian A: Lithostrotion, Dorlodotia, Kullmannophyllum n.gen., Lonsdaleia, Gangamophyllum; Namurian B/C: Dorlodotia, Caninia, Westphalian A: Caninia, Skolekophyllum, Kionophyllum; Westphalian C/D: Dorlodotia, Koninckophyllum, Caninia, Bothrophyllum, Ivanovia, Kionophyllum; Lower Stephanian: Corwenia, Kionophyllum. Also problems of coral taxonomy, evolutionary trends and the significance of environmental influences are discussed.

11967 <TITLE>Taphonomic alterations in upper Viséan dissepimented rugose corals from the Sierra del Castillo unit (Carboniferous, Córdoba, Spain).</TITLE>

11968 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 214, 1-2: 135-153.</SOURCE>

11969 <ABSTRACT>Dissepimented rugose corals are common in the Sierra del Castillo Unit (upper Viséan from SW Spain). A complete taphonomic study has been made of the corals from three localities, each representing different environmental conditions: Antolín rocks are interpreted as mid-ramp and contains mainly reworked corals from reefs, Sierra del Castillo rocks are regarded as originating on a shallow-water platform, and Sierra de la Estrella rocks are typical of the middle to outer platform. The occurrence and distribution of taphonomic features are different at each outcrop and even in each bed, but a general temporal scheme with the timing of all processes is proposed. Borings, encrustations, fragmentation, abrasion, recrystallization, compression, stylolitization, silicification, cleavage, dissolution, and ferruginization are documented. Some processes which are generally regarded as biostratinomic (borings and encrustations) and even as fossil diagenetic (cementation) began before the death of the polyps. Other processes occurred only during the biostratinomic phase (abrasion) or during the fossil diagenetic phase (silicification, stylolitization, cleavage), but many processes occurred during both the biostratinomic and fossil diagenetic phases (fragmentation, cementation).</ABSTRACT>

11980 <TITLE>Serpukhovian (Mississippian) rugose corals with dissepiments from the La Cornuda section (Córdoba, Spain).</TITLE>

- 11981 <SOURCE>Coloquios de Paleontología 55: 51-101.</SOURCE>
- 11982 <ABSTRACT>This paper deals with the dissepimented rugose corals from La Cornuda (Córdoba, Spain). The section is composed of terrigenous and carbonate sediments, Serpukhovian in age (Early Namurian). Rugose corals have been identified only in units 1 and 7; 23 species that correspond to 13 genera belonging to 4 suborders, have been identified. A new genus and two new species included in the subfamily Amygdalophyllinae are described here: Amygdalophyllum cornudensis sp.nov. and Guadiatia pseudocoloniale gen. nov., sp.nov. Two endemic genera belonging to the Lithostrotionidae and the Axophyllidae are maintained in open nomenclature owing to the scarcity of the material.</ABSTRACT>

- 12007 <SOURCE>Geobios 35, 2: 187-200.</SOURCE>
- 12008 <ABSTRACT>The disused quarry east of Castelsec offers a view of shallow-marine carbonates of the poorly known Uppermost Mississippian of the Montagne Noire. At Castelsec, sections are studied in two characteristic facies types (bioclastic wackestone and microbial dominated boundstone) of the Upper Mississippian. The succession is rich in rugose corals and carbonate microfossils. Six genera with seven species belonging to a rugose coral fauna consisting of at least eight genera with several species are described herein; Dibunophyllum castelsecensis sp.nov. is described as new. Twenty-seven carbonate microfossils of different groups have been identified. The Castelsec succession is Brigantian in age, based on the stratigraphic occurrence of rugose corals, foraminifers, and calcareous algae observed in both sections. The rugose coral fauna shows relationships with the well-known fauna of northwestern Europe and the Ouralian-Asian Province. Typical elements of northwestern Europe are missing at Castelsec and vice versa. The differentiation between north and south is interpreted as responses to different palaeolatitudes and tectonic settings.</ABSTRACT>

12020 <SOURCE>Kölner Forum für Geologie und Paläontologie 10: 1-155.</SOURCE>
12021 <ABSTRACT>The habitats of colonial rugose corals - reef coral fauna of Hill 1938 - are investigated in the upper Lower Carboniferous (Mississippian) of western Europe. The studied area consists of two geotectonic realms, the stable southern shelf of Laurussia (Belgium, Great Britain, Ireland) and the southern shelf of Armorica (Southern France), which has been reworked during the Variscan orogeny. Based on the diversity and frequency of colonial taxa, the distances of the colonies, the lateral and vertical dimensions of the single corals occurrences, and their facies setting, six gradually intermerging ecotypes are differentiated: A: level-bottom communities, B: coral meadows, C: biostromes, D: mound-dwelling communities, E: bioherms, divided into the subtypes corals-microbe reefs (E1) and coral reefs (E2) and F: reef complexes. This division is applicable to coral-bearing bioconstructions on a world-wide scale. The analysis of the habitats shows that colonial rugose corals actively contributed to reef-formation in bioherms and reef complexes, and partly in biostromes. Coral-dominated bioconstructions are more frequent than hitherto and occur in all shallow-water carbonate systems studied. Colonial rugose corals are dwellers in various microbial shallow-water mounds. The potential of rugose corals to form bioconstructions is mostly limited to frame-building due to their inability to encrust substrates. Only exceptionally intergrowing cerioid rugose corals actively stabilized certain bioconstructions. Normally, encrusting and binding was achieved by associations of microbes, algae, and bryozoans. This fundamental functional difference provides the differentiation of coral-microbe reefs and coral reefs. Generally, Mississippian coral-dominated bioconstructions consist only of a pioneer stage; a true diversification is never observed and domination stages developed rarely. The bioconstructions had been limited to one 4th or 5th order sequence. Their growth was restricted by a complex system of limiting factors. High-frequency eustatic sea-level fluctuations and/or siliciclastic input and biotic competition are the most important factors on a local scale. Rapidly varying, they caused only briefly ecological niches resulting in small and undifferentiated biotic buildups. The faunal turnover at the Mid-Mississippian Boundary caused final collapse of the coral-dominated Late Mississippian bioconstructions. The study of coral-dominated bioconstructions also supplied new litho- and biostratigraphic data in the western Europe Asbian to Serpukhovian. The monography also includes a taxonomic description of the important rugose corals in late Lower Carboniferous bioconstructions.</ABSTRACT>

</TITLE>
12033 <SOURCE>Coloquios de Paleontología 52: 85-94.</SOURCE>
12034 <ABSTRACT>Viséan rugose corals with aulos are studied in this paper. Corals are recorded in four localities from three areas (Sierra de Castillo, Sierra de la Estrella and Peô arroya) at the Guadiato Area (Ossa Morena). Three species belonging to two genera have been identified and described in detail: Solenodendron furcatum, Solenodendron horsfieldi and Aulokoninckophyllum carinatum. Aulokoninckophyllum carinatum and Solenodendron horsfieldi are recorded for the first time in Spain. Microstructural features of Solenodendron are described for the first time. Solenodendron possesses septa with fibrous (water-jet) microstructure. On the contrary, Aulokoninckophyllum shows trabecular microstructure of the septa in the dissepimentarium. The trabeculae are disposed as a fan system. When the septa reach the tabularium the trabeculae are substituted by fibrous microstructure with water-jet disposition. Microstructural differences between Solenodendron and Aulokoninckophyllum allow to propose evolutive origin for these two genera.</ABSTRACT>

12071 <TITLE>Life strategies of solitary undissepimented rugose corals from the upper member of the Picos de Europa Formation (Moscovian,

- Carboniferous, Cantabrian Mountains, NW Spain).</TITLE>
- 12072 <SOURCE>Lethaia 34, 3: 203-214.</SOURCE>
- 12073 <ABSTRACT>Rugose corals belonging to the orders Metriophyllina, Stereolasmitina and Plerophyllina have been identified in the upper member of the Picos de Europa Formation (Moscovian). Corals occur in crinoidal limestones containing common bryozoans. The coral assemblage shows a high diversity. Mode of preservation and spatial distribution of corals demonstrate close relationships with biogenic components such as crinoids, bryozoans, brachiopods and bivalves. The morphology of corals provides valuable data for identifying their life strategies, for which have been identified: liberosessile with straight growth, liberosessile with curved growth, fixosessile with straight growth and fixosessile with curved growth. Most corals from the Picos de Europa Formation appear to have been fixosessile with straight growth; they attached themselves to bioclasts and subsequently developed radiciform processes (mainly talons) to remain straight.</ABSTRACT>

- 12111 <SOURCE>Trab. Geol. Univ. Oviedo 16: 37-60.</SOURCE>
- 12112 <ABSTRACT>Systematic studies of Carboniferous corals in the Cantabrian Mountains of northern Spain have progressed to the point where they are quite useful for biostratigraphic and zoogeographic analyses. This report presents a distribution analysis based on 1369 specimens assigned to 163 species representing 56 genera of rugose corals. A preliminary biostratigraphic zonation based on generic ranges is useful to identify series or stages of Carboniferous in the area studied. Twenty-nine genera are known only from one series or stage, 25 genera are not known to occur below a particular series or stage, and 16 genera are not known to occur above a particular series or stage. Future studies should be directed toward construction of a time scale independent series of stage boundaries. Coral abundance, frequency of occurrence, generic and specific diversity, influx of new genera, and morphotype diversity, all known maxima in Namurian A-B, Westphalian A, and Westphalian D, and intervening minima in Visean, Namurian C, Westphalian B, and Cantabrian-Stephanian A. Because most of the rugose coral genera originated outside the area studied, these maxima and minima seem to represent invasions and retreats of the coral fauna related with changes in coral habitats. Although there is a general correlation of increased abundance and diversity with regression of the sea through Late Carboniferous time in northern Spain, smaller cyclical variations in abundance and diversity are related to increases in habitat size (ecospace) and habitat diversification. A general migration of corals from deep-water environments to generally shallow water environments through late Carboniferous time is similar to pattern seen in the Lower Carboniferous of the western conterminous USA and may be related to larger regional events. Zoogeographic comparisons with North America and the Donetz Basin of the USSR by means of similarity index (SI) suggest that a sea way along the juncture of the African, South American, and North American plate provided a communication route for coral gene flow between Spain and North America during the entire Late Carboniferous.</ABSTRACT>

12123 <TITLE>Les Tetracoralliaires (Rugosa) du Carbonifere inferieur du Massif Armoricaïn (France).</TITLE>
12124 <SOURCE>Rennes Univ. I Diss. [in French; unpublished?].</SOURCE>
12125 <ABSTRACT>Après avoir defini le cadre geologique et la lithologie au Carbonifere inferieur, la terminologie et la classification utilisees pour les Tetracoralliaires sont precisees. L'etude systematique porte sur des nombreux specimens, dont les caracteres externes et internes sont decrits et figures. Des methodes d'analyse biometrique ont ete utilisees. Les taxons etudies appartiennent a l'ordre Stauriida et se repartissent dans huit sous-ordres, quatorze familles: Stauriina (Famille Amplexidae), Metriophyllina (Famille Cyathaxoniidae), Stereolasmatina (Familles Antiphyllidae, Hapsiphyllidae, Zaphrentoididae), Plerophyllina (Familles verbeekiellidae, Lophophyllidiidae, Hexalasmataidae), Caniniina (Familles Cyathopsidae, Uralinidae), Lonsdaleiina (Famille Axophyllidae), Aulophyllina (Familles Palaeosmiliidae, Aulophyllidae), Lthostrotionina (Famille Lithostrotionidae) et sous-ordre et famille incertains; vingt-neuf genres dont quatre nouveaux (Nominoephyllum, Delepinella, solemnophyllum, sabolia). ainsi que quarante-cinq especes dont douze nouvelles. Ce chapitre comporte egalement des donnees sur l'insertion septale chez Delepinella anastomose et sur quelques tendances evolutives relatives aux genres Siphonophyllia et Aulokoninckophyllum. La partie biostratigraphique est consacree a la repartition verticale des genres et des especes. Un essai de biozonation a ete tente pour les especes d'age tournaisien superieur a viseen moyen. Enfin, divers aspects de la paleoecologie des Tetracoralliaires ont etes traitees. L'environnement sedimentaire regit la repartition des differentes especes. L'analyse paleoautoecologique montre que suivant leurs formes externes et leurs caracteres internes, certains polypiers peuvent caracteriser un environnement particulier. Differentes associations a Tetracoralliaires ont ete reconnues, semblant se repartir en fonction d'un gradient bathymetrique; les differences observees aux niveaux generique et specifique resulteraient de l'influence des facteurs de l'environnement (turbulence de caux, nature des sediments). Dans le meme chapitre, des comparaisons sont tentees avec les faunes d'autres regions (Europe occidentale, Nord de l'Afrique, Europe orientale, Asie). De fortes similitudes au niveau specifique et generique apparaissent entre le domaine armoricaïn, l'Europe occidentale, le Nord de l'Afrique et meme la Siberie (Bassin de Kuznetsk).</ABSTRACT>

12150 <SOURCE>Abhandlungen und Berichte für Naturkunde 29: 23-71.</SOURCE>
12151 <ABSTRACT>The Late Tournaisian (Early Chadian, Levitusia humerosa Zone, Cromford Formation) of Ratingen (Velbert Anticline, Rhenohercynian Zone of Variscides) yields Cyathoclisia (Cyathoclisia) modavensis (Salée 1913). There are only two further localities of this common index coral in Germany: an olistolith of Carboniferous limestones within the Bavarian facies of Culm measures in Upper Franconia (Saxothuringian Zone of Variscides), and a borehole on the Baltic Sea island of Rügen (carbonate ramp, southern margin of Baltoscandia). The amygdalophyllid genus widely distributed in the late Early Tournaisian (late Hastarian) and in the Late Tournaisian (Ivorian, Early Chadian) of Europe and Asia is provisionally subdivided into two subgenera: Clisaxophyllum Grabau in Chi 1931 (minor septa short, never contracline) and Cyathoclisia Dingwall 1926 (minor septa long and contracline, with biform tabulae, sometimes with diplosepta arising in maturity), but the actual obsolete taxonomy of the genus and the 27 named species requires much additional revisions. The rare German materials and a comparative English sample from Clitheroe (Lancashire) give first doubts about the current, since 1981 accepted synonymy of Cyathoclisia tabernaculum Dingwall 1926 and Cyathoclisia modavensis (Salée 1913). Emended future diagnosis of specific taxa are in strong need of studied populations and revised type specimens, especially of the extremely rich Russian Cyathoclisia communities; here the classical collection of Ludwig (1862) from the Ural Mountains is well preserved in the university of Göttingen.</ABSTRACT>

12162 <TITLE>Distribution and palaeogeographic affinities of Belgian Tournaisian rugose corals.</TITLE>
12163 <SOURCE>Mem. Ass. Australas. Palaeontols 8 [Jell P. A. & Pickett J. W. (eds): Fossil Cnidaria 5 (Proceedings of the Fifth International Symposium on Fossil Cnidaria including Archaeocyatha and Spongiomorphs)]: 267-273.</SOURCE>
12164 <ABSTRACT>New research in the Tournaisian of Belgium and adjacent areas has yielded rugose coral faunas that are generally more diversified than those from the classical Tournai area. These faunas permit definition of three Tournaisian coral zones. The oldest one, whose base coincides with the Devonian-Carboniferous boundary, includes Melanophyllum, Caninia tregaensis, Saleelasma, Siphonophyllia, and Cyathaxonia. Some of the corals of this zone show affinities with those of Sando & Bamber's Zone I in the western Interior Province of North America and also with corals from the lower Tournaisian of the USSR. The second zone is characterized by an abundant but low diversity fauna including Lophophyllum and Siphonophyllia. The youngest coral zone has the most diverse fauna with Caninophyllum, Uralinia, Siphonophyllia, Cyathoclisia and Solenodendron. Corals of this zone are

- known in the upper Tournaisian of Asia (USSR and China).</ABSTRACT>

- 12190 <ABSTRACT>Rugose corals occur in all the calcareous units. Thirty six species are described. Colonial and solitary corals show distributions clearly related to the original environment represented by each unit. Nevertheless, the appearance patterns of the colonial corals are similar to those described by Poty (1984, 1985) for western Europe, providing higher biostratigraphic resolution than other fossil groups. Colonial rugose corals built biostromes in unit 1. Dominant species is Siphonodendron martini, but more than 15 other colonial and solitary species also occur in that unit. Massive corals are common in unit 3, where first appearance of Diphyphyllum furcatum is recorded. Units 4 to 6 yielded mainly undissepimented solitary corals, with high abundance of Zaphrentites and Uflmia. Some colonial specimens of the species Lithostrotion decipiens and Siphonodendron aff. pauciradiale also occur.</ABSTRACT>

- 12202 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 209-223.</SOURCE>
- 12203 <ABSTRACT>Solitary dissepimented rugose corals occur in muddy limestones and marls at Ribadesella quarry (Lower Moscovian, Eastern Asturias, NW Spain). Diversity is low and most corals belong to the families Aulophyllidae and Cyathopsidae. Geyerophyllidae, which are dominant in most Moscovian coral localities from the Eastern Cantabrian

Mountains, are scarce in this outcrop. The taxonomic features of this assemblage are described in detail. These corals inhabited soft-bottom environments, probably below the wave-base, and periodically subject to notable water movements. They developed diverse adaptations to these conditions, and many of them were able to change their growth direction several times. Additionally, they provided a substratum for development of bryozoans, auloporoids and chaetetids, which also grew on brachiopod shells. Most specimens are covered by algal crusts containing up to three kinds of algae; borings and other kinds of postmortem disturbances are not common.

 12215 <SOURCE>Palaeontographica A252: 23-92.</SOURCE>
 12216 <ABSTRACT>The Picos de Europa Formation consists mainly of massive, white to light grey limestones. In its upper member, beds of red to pink, marly, crinoidal limestones contain a rich rugose coral fauna. Its age is Upper Carboniferous (Kashirian to Myachkovian, middle and upper Moscovian, = Westphalian C, Bolsovian, and Westphalian D). Rugose corals of the suborders Cyathaxoniina Spasskiy (Metriophyllina sensu Hill, tentatively including the superfamily Duplocariniidae Fedorowski), Zaphrentoidina Schoupe and Stacul (Stereoplasmatina sensu Hill) and Plerophyllina Sokolov are described. Thirty-one species belong to 18 genera are identified; 9 species are new (Cyathaxonia pinguis, Neaxon ? multitabulatus, Trochophyllum ? variable, Kabakovitchiella triformis, Lophotichium ? espinerense, Ufimia accelerata, Lophophyllidium picoensis, Wannerophyllum carbonicum and Wannerophyllum incertum); 11 species are described in open nomenclature.

 12228 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 127-139.</SOURCE>
 12229 <ABSTRACT>In Belgium and Northern France, the middle part of the Visian is composed of massive open-marine limestones (Neffe Formation, V2a) which laterally contain two different rugose coral assemblages. The first one yields abundant Dorlodotia briarti, Siphonodendron undulosum, Palaeosmia murchisoni and few Caninophyllum cf. patulum and Axophyllum mendipense. This assemblage occurs mainly in very turbulent shallow-water grainstones. The second one includes numerous Axophyllum mendipense, Siphonodendron undulosum and Palaeosmia murchisoni, but other species are lacking; this assemblage occurs mainly in shallow-water bioclastic packstones and grainstones. These

two assemblages are considered as corresponding to different bathymetric environments. *Dorlodotia briarti* lived in a shallower-water environment as *Axophyllum mendipense*, whereas the species common in both assemblages (*S. ondulosum* and *P. purchisoni*) can show more or less important differences in their morphological characteristics which allow recognition of ecotypes. The results are compared with an assemblage from England (Orton, Ravenstonedale) which is composed of similar species than the assemblage with *D. briarti* (additionally with *Siphonodendron sociale*) and occurs in a quiet shallow-water environment. A model of the bathymetric and hydrodynamic influences on the morphology of these corals is suggested. </ABSTRACT>

12240 <TITLE>The Siphonodendron Limestone of the Los Santos de Maimona Basin: development of an extensive reef-flat during the Visean in Ossa Morena, SW Spain.</TITLE>
12241 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, Vol. 2]: 203-214.</SOURCE>
12242 <ABSTRACT>The Los Santos de Maimona Basin in Ossa Morena (SW Spain) includes 8 lithostratigraphic units numbered from 0 to 7. Unit 1, which constitutes the subject of the present contribution, is composed of marls and limestones with interbedded volcanic rocks of basaltic composition. Limestones and marls contain abundant colonies of the rugose genus *Siphonodendron*. Large brachiopods, algae and tabulate corals participate in the framework. Solitary corals, gastropods, bryozoans, ostracodes and foraminifers are also common. The Siphonodendron Limestone shows a vertical lithologic evolution from marls at the base to limestones at the top. Facies are ordered into five associations which correspond to reef-flat sequences and storm episodes. This unit, interpreted as a reef-flat, extends over the whole basin, although the thickness, the development of the framework and the distribution of organic components vary from SE (seaward) to NW (landward). The main environmental factors controlling the development of the organic framework are the tidal regime, minor subsidence pulses and periodical storms.</ABSTRACT>

12281 <ABSTRACT>The taphonomic analysis of the solitary undissepimented corals from the calcareous units at the "Los Santos des Maimona" Lower Carboniferous Basin is carried out. Two kinds of taphonomic observations are made: 1. Areal distribution of the specimens at each outcrop and relationship between them. 2. Preservational phenomena for each specimen (microborings, colonizations, fractures, recrystallization, cementation and infilling, diagenetic compression and abrasion). All these phenomena are analysed to identify the original environment in which the corals lived, and their diagenetic history.</ABSTRACT>

12293 <SOURCE>Archaeologie im Ruhrgebiet; Geologie, Palaeontologie und Vor- und Fruhegeschichte zwischen Lippe und Wupper 2 [C. Hackler, A.Heinrich & E.-B. Krause (eds)]: : 151-172.</SOURCE>
12294 <ABSTRACT>German lower Visean (Arundian) records of Dorlodotia (Dorlodotia) briarti Salee 1920 are: 1. Busbach near Aachen (Ardennes, Rhenohercynian Variscan Zone); 2. drillhole Loissin 1/1970 (near Greifswald, Mecklenburg-Vorpommern, SW margin of the East European Platform; with biostratigraphic data for the Lower Carboniferous sequence of Brigantian-Asbian Culm Measures and Arundian Carboniferous Limestone). Notes on taxonomy and Eurasian Chadian-Arundian species of Dorlodotia salee 1920 (including subgenus Pseudodorlodotia Minato 1955) are followed by a stratigraphic review of index fossils (W Europe, NW and S China): Dorlodotia (Pseudodorlodotia) pseudovermicularis (M' Coy 1849), Dorlodotia (Dorlodotia) briarti Salee 1920, Dorlodotia (Dorlodotia) mui Luo in Luo & Zhao 1962, Dorlodotia (Dorlodotia) asiatica (Yu 1934) and similar so-called "Thysanophyllum" / Thysanophylloides species. Upper Carboniferous Dorlodotia-like taxa are classified within Lytvophyllum Dobrolyubova in Soshkina, Dobrolyubova & Porfir'ev 1941; Visean species of N America are members of Acrocyathus d'Orbigny 1849.</ABSTRACT>

12306 <SOURCE>Annales de la Societe geologique du Nord 37, 2: 133-139. [in French, with English abstract]</SOURCE>
12307 <ABSTRACT>The very scarcity of the corals in the Chateaulin basin is emphasized and the only specimen of Rugosa collected in the Caouennet conglomérat is accurately described (structure and microstructure). It is assigned to Aulokoninckophyllum sp. aff. carinatum (Carruthers 1909), despite the somewhat uncertain identity of the specimen, the age given by the microfauna is precised and the pebbles of conglomerate dated as the Upper Visean.</ABSTRACT>

12539 <TITLE>Habitats of colonial rugose corals: the Mississippian of western Europe as example for a general classification.</TITLE>
12540 <SOURCE>Lethaia 43, 4: 558-572.</SOURCE>
12541 <ABSTRACT>Colonial rugose corals are a major constituent of shallow-water marine benthic communities in Mississippian times. The study of western European rugose coral habitats from the base of the Tournaisian stage to the Serpukhovian stage allows the recognition of four basic habitat types, which can be divided into a total of 11 subtypes. The classification is mainly based on field data, and thus rapidly applicable. Level-bottom communities in which large colony distances are characteristic (type A) represent the most basic community type; polyspecific (subtype A1) and monospecific (subtype A2) subtypes occur. Reduced colony distances result in the formation of coral meadows (type B), which either show homogeneous coral distribution (subtype B1) or the development of patches (subtype B2). Coral biostromes (type C) represent a spectrum between hydrodynamically controlled biostromes (nothing in place, subtype C1) and biologically constructed and controlled biostromes (subtype C2). The bulk of the biostromes represent mixtures of these two subtypes (subtype C3). Colonial rugose corals are widely encountered in Mississippian bioherms where they are dwellers (subtype D1), form capping beds (subtype D2), support framework building along with other organisms (subtype D3) and form coral framework (subtype D4). The latter is probably the most uncommon of all subtypes in Mississippian times. The classification is widely applicable to other groups. [original abstract]</ABSTRACT>

12552 <TITLE>Paleoenvironmental analysis based on rugose corals and microfacies: a case study at La Cornuda section (early Serpukhovian, Guadiato Area, SW Spain).</TITLE>
12553 <SOURCE>Lethaia 42, 1: 39-54.</SOURCE>
12554 <ABSTRACT>Combined analysis of microfacies and rugose coral features provides a useful tool for palaeoenvironmental studies in areas where outcrops are not appropriate for field observations. A detailed study of Serpukhovian rugose corals from La Cornuda section (Guadiato Area, SW Spain) by means of thin sections allowed the identification of environments where they lived. All corals were collected in unit 1 of the section where three different but intimately connected environments have been identified. Corals developed mainly in small mounds built jointly by microbial communities, algae and corals. Some corals also lived in calcareous shoals mainly composed of echinoderm plates. Finally, some corals occur in oncoidal limestone that represents a shallow ramp, but they were mainly transported from shoals and mounds. [original abstract]</ABSTRACT>

12578 <TITLE>The Lower Visean Rugosans from Cantabria (Spain).</TITLE>
12579 <SOURCE>FC&P 14, 2: 26.</SOURCE>
12580 <ABSTRACT>Horn corals from the Lower Visean of Northern Spain, e.g. the "Marbre Griotte facies" of the Cantabrian Mountains, are subject of a recent investigation program together with J. Kullmann, Tübingen. Corals are rather rare in this facies, but their taxonomy is surprisingly diversified. In addition to the earlier description by Kullmann (1966) it was possible to distinguish some new species of *Ufimia* Stuckenberg 1895, as well as other not fully identified plerophyllids and polycoeliids, several new species of *Rylstonia* Hudson & Platt 1927; *Rotiphyllum* Hudson 1942; *Weyerelasma* Kullmann & Liao 1985 and some forms of *Zaphrentes* Hudson 1941; *Cyathoxonia* Michelin 1846; "Permia" Stuckenberg 1895, and another aulate coral similar to *Neaxon* Kullmann 1965, as well as corals showing close similarity to *Metriophyllum* Milne-Edwards & Haime 1851. A new genus similar to *Claviphyllum* Hudson 1942, was already distinguished, but possessing the alar septa equal to other major septa and a kind of the key-hole counter pseudofossula developed. There are also some forms represented by single corallites showing morphology so strange that we decided to postpone the detailed description of them to the time of

collecting additional material. The fauna being investigated can by now be compared only to the Lower and Middle Visean faunas described from Great Britain in the series of papers by Hudson (1936 to 1945) and to the Upper Tournaisian fauna described by Weyer (1975) from the Island Hiddensee. Some elements of that fauna can also be found in Thuringia (Weyer 1984) and other regions of Europe in which the corals-bearing cephalopod facies of the Lower Carboniferous is developed.

12593 <ABSTRACT>Four reworked specimens of Sychnoelasma Sando 1961 have been collected from Serpukhovian olistolithic beds of Guadiato Valley (SW Spain). No strata of the usual age of Sychnoelasma (Tournaisian to Lower Visean) occur in Guadiato Valley. Several factors, including evidence of reworking, the age of associated fossils, and the biostratigraphic distribution of Sychnoelasma at other localities, suggest that the corals were derived from older strata, subsequently exhumed by erosion, and deposited in younger beds. Morphological and microstructural analyses of the Guadiato Valley specimens show the presence of fossular crests which are conspicuous only in specimens with deep calices. These observations suggest a close relation between Sychnoelasma and the genus Ankelasma. [original summary]</ABSTRACT>

12604 <TITLE>Contribution of rugose corals to Late Viséan and Serpukhovian bioconstructions in the Montagne Noire (Southern France).</TITLE>

12605 <SOURCE>SEPM Special Publications 78 / AAPG Memoir 83 (Permo-Carboniferous carbonate platforms and reefs): 119-132.</SOURCE>

12606 <ABSTRACT>Coral-bearing bioconstructions are described for the first time from upper Lower Carboniferous (Upper Mississippian) shallow-water limestone olistoliths of the southern Montagne Noire (Mont Peyroux Nappe), southern France. Microbial-induced wackestones and microbial boundstones dominate major parts of the Brigantian Roque Redonde Formation and Serpukhovian Roc de Murviel Formation, which follows on top of a paleokarst. Further subtidal facies are intercalated. The short-lived bioconstructions consist of thin monospecific and polyspecific coral biostromes, coral bioherms (patch reefs) growing in high-energy turbulent environments, and a single example of a large shallow-water microbial buildup that formed below fair-weather wave base in dimmed light. The contribution of rugose corals to the bioconstructions varies from active framebuilding in the biostromes and bioherms to passive dwelling of sparse fauna in the microbial buildup.

Microbial structures are of special importance within polyspecific biostromes and patch reefs. In a delicate balanced system they are responsible for growth or suffocation of the coral-dominated bioconstructions. That co-occurrence of coral boundstones and microbial boundstones appears to be a widespread characteristic of small reefs in Late Visean and Early Serpukhovian time. Factors limiting the growth of the bioconstructions in southern France include rapid sea-level variations, tectonic instability of the shelf, and intrinsic paleobiological features of the rugose corals, like their fragility and inability to encrust mobile substrates. Comparable upper Lower Carboniferous coral-bearing bioconstructions of the Paleotethys realm and the epeiric seas of northwestern Europe are discussed. [original abstract]

12645 <ABSTRACT>Dissepimental rugose corals are frequent in the Sierra del Castillo Unit (Guadiato Area, Ossa Morena) which is composed mainly of Viséan limestones. Aulophyllid corals from Sierra del Castillo, Sierra de la Estrella (both near Espiel, Córdoba) and Antolín (near Peñarroya, Córdoba) have been studied. Ten species belonging to the genera Aulophyllum, Auloclisia, Clisiophyllum, Axoclisia, Dibunophyllum, Arachnolasma, Koninckophyllum and Amygdalophyllum have been described. The genus Axoclisia is for the first time described in Europe. The microstructure of all species is described in detail.</ABSTRACT>

12656 <TITLE>Caninoid Rugose Corals of the Lower Tournaisian (Hastarian) of Belgium: systematics and evolution.</TITLE>
12657 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 91, 1/4: 73-84.</SOURCE>
12658 <ABSTRACT>The revision of the caninoid rugose corals of the Lower Tournaisian (Hastarian) of Belgium and the comparison with species from others regions allow recognition of 4 species and 9 subspecies belonging to 3 genera: Siphonophyllia, Uralinia and Coniophyllum and to establish some of their phylogenetic relationships. Coniophyllum is first represented by a small opportunist species (Coniophyllum priscum (Muenster), which colonized the deep water and platform areas just after the Devonian / Carboniferous boundary crisis (top of the Siphonodella praesulcata conodont biozone). It gave rise through a process of hypermorphosis to Coniophyllum streeli, a species which seems to be adapted to the shelf facies. Siphonophyllia cylindrica hasteriensis appears near the base of the Tournaisian and gave rise to Siphonophyllia rivagensis through a process of acceleration. Morphotypes of Coniophyllum streeli show morphological characters which are similar to those observed in the genus Siphonophyllia and suggest a homeomorphic trend. The relationships between the genus Uralinia and Siphonophyllia are defined on the basis of their ontogeny. The latter probably gave rise to the former. The stratigraphic distributions of all these species are defined.</ABSTRACT>

12670 <SOURCE>Annales de la Société géologique de Belgique 117, 1: 201-225.</SOURCE>
12671 <ABSTRACT>The caninoid Rugosa from the Belgian Hastarian have been

revised from specimens found in some sections of the namur-Dinant Basin and the vise-Maastricht area (Campine Basin), and from the original material of Salee (1913). This author has described two species: Siphonophyllia ("Caninia") cylindrica hasteriensis Salee and Caninia dorlodoti Salee. The second one has been defined from specimens which are assigned here to Siphonophyllia cylindrica hasteriensis, and other ones considered as being Hastarian, but coming in fact from the Strunian (Campophyllum flexuosum Goldfuss). So, that species, and in the same way Endophyllum transitorium Groeber 1910, are considered as not valid. Four other species, including three new ones, and a new genus are described: Coniophyllum streeli nov. gen. nov. sp. from the subzone RC1P, Siphonophyllia rivagensis nov. sp., from the zone RC2, and Uralinia lobata nov. sp. from the subzone RC1, and the zone RC2.

12697 <ABSTRACT>Upper Carboniferous (Westphalian) solitary corals (Rugosa) of the type "Cyathaxonia fauna" are described from the Ojosa formation of Casavegas in the eastern part of the Cantabrian Mountains (North Spain) belonging in the Upper Westphalian D (corresponding to the upper "Myachkovichian", uppermost Moscovian). The described coral fauna comprises 7 species belonging to the genera Cyathaxonia, Amplexocarina?, Zaphrentis, Calophyllum, Sochkineophyllum, Ufimia and Lophophyllidium. Two species are new: Amplexocarina? palentina n.sp. and Sochkineophyllum accelerans n.sp. The characteristic composition of the Casavegas fauna with representatives of Cyathaxonia, Zaphrentites and Polycoeliids (s. l.) is only known from four Cantabrian localities ranging from middle Westphalian D till Cantabrian (lower Stephanian A); no other coeval faunas of comparable composition seem to exist. The Casavegas fauna seems to be restricted to still water facies of slightly greater water depth; it marks the highest point within the sea-level changes at the end of the Westphalian. Regional tectonic

- unrest hindered the spreading of this fauna.</ABSTRACT>

- 12710 <ABSTRACT>The "Picos de Europa" Formation consists mainly of massive, white to light grey limestone. Its upper member contains some beds of red to pink, marly crinoidal limestone with a rich rugose coral fauna. Laccophyllidae, Cyathaxoniidae, Lophophyllidiidae and Lophotichiidae are predominant. The environmental conditions of these beds seem to be those of a shallow shelf. The fauna is unquestionably of Moscovian age, determined by the presence of Fusulinella, and it is similar to uppermost Carboniferous and lower Permian coral assemblages from North America and the Carnic Alps. The presence of some elements characteristic of uppermost Carboniferous and lower Permian (e.g. Wannerophyllum) suggests that the "Picos de Europa" fauna is a precursor of Permian coral faunas. The affinities of the "Mediterranean" Picos de Europa fauna with corals of the North American realm suggest a close connection between these regions during the Late Carboniferous.</ABSTRACT>

- 12774 <SOURCE>Mededelingen Rijks Geologische Dienst 35, 1: 1-161.</SOURCE>
- 12775 <ABSTRACT>Des recherches effectuees sur les coraux du Viseen beige ont abouti a l'identification de 72 especes de Tetracoralliaires, dont 63 (parmi lesquelles 19 sont nouvelles) sont decrites ici, et de 4 especes de Heterocoralliaires, dont 3 sont egalement decrites. Des variations morphologiques observees dans certaines de ces especes, comme par exemple la presence ou l'absence de processus de connexion chez les siphonodendron, ou encore le developpement temporairement fascicule de certaines colonies de Lithostrotion deeipiens, ont par-fois pu etre mises en relation avec des conditions particulieres de l'environnement. Par centre, d'autres variations paraissent etre la manifestation de tendances evolutives et ont permis de preciser les relations phyletiques probables existant entre les especes des genres Lithostrotion, Siphonodendron et Diphyphyllum reconnues en Belgique et en Grande-Bretagne, eellesexistent entre le genre Bothrophyllum et le genre Caninophyllum ou, encore qui semblent lier les genres Lonsdaleia, Dorlodotia, Corphalia et Thysanophyllum. Les

coraux presents dans chacune des deux grandes aires paleo-geo-graphiques reconnues en Belgique – le bassin de Namur-Dinant et le bassin de Campine-Brabant -- peuvent etre distincts ou posseder des repartitions stratigraphiques differentes qui suggerent l'absence relative de communications entre ces aires. Les coraux du bassin de Namur-Dinant ne montrent que de faibles affinites avec ceux connus en Angleterre dans la province du Sud-Ouest et en Irlande, ce qui suppose l'existence de relations etroites entre ces regions. Ceux du bassin de Campine-Brabant possedent par contre de nombreuses affinites avec ceux du centre et du Nord de l'Angleterre, d'Afrique du Nord et d'U.R.S.S.; ce bassin etait done apparemment plus ouvert aux influences exterieures que le bassin de Namur-Dinant. Une zonation du Viséen basee sur les coraux est proposee pour le bassin de Namur-Dinant.

12788 <ABSTRACT>Limestone pebbles of the post-lower Bashkirian Harbella Formation (Malaguides, internal zone of the Betic Cordillera) yielded sixteen species of rugose corals belonging to eleven genera and two species of heterocorals belonging to two genera. The fauna is uppermost Viséan age (V3b-V3c). Its paleogeographic significance within the western Mediterranean is discussed. *Lonsdaleia corbariensis*, known up to now only from debris flow deposits of the Mouthoumet massif (Southern France), covers approximately half of the total fauna. *Hexaphyllia mirabilis* is shown to have juvenile stages with five septa.

12799 <TITLE>Stratigraphy of rugose corals in the Dinantian of the Boulonnais (France).</TITLE>

12800 <SOURCE>Memoires de l'Institut Geologique de l'Universite Catholique de Louvain 35: 51-82.</SOURCE>

12801 <ABSTRACT>35 species of Rugosa and 2 species of Heterocorallia have been recognized in the Dinantian of the Boulonnais. Their stratigraphic distribution and new information about the lithostratigraphy support, and in some cases improve the accuracy of, correlations with Belgium proposed in earlier studies. Several formations defined in the Belgian Namur-Dinant Basin can be formally recognized in the Boulonnais. The Hure Dolomite equates with the Namur Formation as it is known in the south part of the Namur synclinorium. It yields two coral assemblages belonging to the RC3 Zone (Ivorian) and to the RC4a Zone (Lower Moliniacian). The Haut-Banc Limestone comprises three units: the Terwagne Formation, the Neffe Formation and the members 945; and 946; of the Lives Formation. The Neffe Formation contains the guide

corals of the *Dorlodotia briarti* and *Corphalia mosae* RC5 Subzones (Upper Moliniacian); member 946; includes at its base the Lithostrotion araneum horizon, which marks the base of the RC6 Zone, and, in the overlying beds, the same coral ecozone as in Belgium. Another ecozone defined in the sequence n°+1 of the member 947; of the Lives Formation characterizes the same sequence in the Siphonodendron martini Dolomite. The Lunel and Napoleon Limestones are respectively equivalent to the Seilles and Grands Malades Formations. The Joinville Limestone includes three units: the Thon-Samson Formation, a stromatolitic unit similar to the Poilvache Formation, and an upper unit rich in Gigantoproductids and Rugose Corals. The latter are distributed in two assemblages corresponding to the RC7 946; Subzone (34;V3b 947; 34;) and the RC8 Zone (34;V3c 34;). The Joinville Limestone is capped by beds which have yielded coral species known in the "Rylstonia shale" in Yorkshire. Differences in the lithology of the upper part of the Neffe Formation and in the member α of the Lives Formation have been observed between the Ferques autochthonous tectonic unit and the Haut-Banc allochthonous tectonic unit: the facies of the first may be compared with those known in the northern part of the Namur syncline, and that of the second with those known in the southern part. The "Banc d 039; or de Bachant", which is between the Neffe and Lives Formations, and the Lunel, Napoleon and Joinville Limestones are considered as isochronous rather than diachronous units, as suggested in recent publications. </ABSTRACT>

12813 <SOURCE>N. Jb. f. Geol. Palaeont. Abh. 149, 1: 1-58.</SOURCE>

12814 <ABSTRACT>The youngest Central European stromatoporoids are described from Lower Tournaisian (Tn 1b, Crinoiden - Kalk von Aachen) biostromes near Kornelimuenster, Aachen. Morphological transitions within 34; species 34; and 34; genera 34; can be recognized according to shape and distribution of skeletal elements. Most species belong to genera which dominate during Middle and Lower Upper Devonian. There is no clear explanation for the 34; extinction 34; of the Paleozoic stromatoporoids at the Devonian / Carboniferous boundary.</ABSTRACT>

12826 <SOURCE>Zeitschrift der geologischen Wissenschaften 11, 4: 1515-1530.</SOURCE>

12827 <ABSTRACT>The Tabulata genera Sutherlandia, Cladochonus, Rossopora? and Smythina and some few solitary Rugosa of a Zaphrentis phase constitute the coral fauna of the Culm shales from Aprath. Growing on crinoid

columns, Cladochonus colonies extend to considerable size and may comprise about 100 corallites. Apart from the autochthonous findings, some allochthonous corals of Carboniferous limestone facies origin occur in Culm facies sediments of the Rhenish Mountains.

12853 <ABSTRACT>Verolites polonicus sp. n. (Tabulata, Syringoporida) from the Lower Carboniferous (Upper Tournaisian, Lower Caninia Z) of the Silesia-Cracow Upland (Dębnik Anticline, Czatkowice Quarry) is described and illustrated. This is the third species of poorly known genus Verolites Tchudinova. The new species differs from the type species (V. rarus Tchudinova) in subcerioidal structure of corallum, composed of prismatic corallites with smaller and undifferentiated diameters, greater number of connecting pores of smaller diameters, very rare connecting tubes, lack of connecting platforms and more strongly developed spines of tabulae.</ABSTRACT>

12865 <SOURCE>Acta Geologica Polonica 52, 4: 497-500.</SOURCE>

12866 <ABSTRACT>The paper presents the results of investigations of Tabulate corals from the Lower Carboniferous (Upper Tournaisian, Gnathodus cuneiformis Zone) from several exposures in the Dębnik Anticline

- (Silesia-Cracow Upland, southern Poland). Two taxa representing the Favositida, *Roemeripora nowinskii* sp.nov. and *Roemeripora* sp., and one species representing the Syringoporida, *Pleurosiphonella* cf. *virginica* (Nelson), are described. The presence of *Michelinia tenuisepta* (Phillips) is noted. The genus *Pleurosiphonella Tchudinova* is recognised in the Carboniferous of Europe for the first time. </ABSTRACT>

12944 <ABSTRACT>The microfloral assemblages of Mississippian carbonate outcrops close to Fuenteovejuna, southwestern Spain, are analysed and the occurrence of new genera and species of Diploporaceae dasyclad algae can be highlighted. Two new taxa are described, Guadiatella delicata n.gen. n.sp., and Borladella alternans n.gen. n.sp. Both taxa are new monospecific genera without equivalence in the Mississippian. They occur in upper Viséan rocks, in the Asbian and Brigantian substages. The genus Japhetella is here considered as an invalid genus. [original abstract]</ABSTRACT>

12955 <TITLE>Growth and diagenesis of cryptalgal-bryozoan buildups within a Mid-Visean (Dinantian) cyclic sequence, Belgium.</TITLE>
12956 <SOURCE>Annales de la Societe geologique de Belgique 115, 1: 187-213.</SOURCE>
12957 <ABSTRACT>Cryptalgal-bryozoan carbonate buildups are reported from the Middle Visean (Upper Dinantian) near Namur, Belgium. They occur in a 20m-thick, upward-shallowing, carbonate rhythm - the thickest in a succession of such rhythms. The rhythm comprises three phases; from bottom to top: (1) packstones-grainstones with rich and diverse biota, indicating open, shallow marine conditions; grading to (2) wackestones, with a poorer and more restricted biota, passing upwards to cryptalgal boundstones; and (3) mudstones with highly restricted and reduced biota. Small- to medium-sized mounds (2-11m thick) occur at the top of phase 2 where they settled on coral thickets. The buildups consist of a meshwork of bryozoans encrusted by finely laminated cryptalgal coatings and encrusting bryozoans. Brachiopods, sponges and vermetid gastropods are also present. Voids were filled by internal sediments and early marine cements. The growth of the buildups was probably interrupted by a short-lived sea-level drop, recorded laterally as what seems to be a karstic surface. Vadose internal sedimentation and minor leaching by meteoric water occurred in the ?exposed buildups. Marine conditions were then restored and, at the beginning of phase 3 deposition, coral thickets (with cryptalgal coatings) colonized the top of the largest buildup. Most remaining pore space was filled by burial cements. Other minor diagenetic processes include neomorphism, dolomitization, precipitation of Ca-sulphates and silicification.</ABSTRACT>

12968 <TITLE>Large multi-biotic cyanoliths from relatively deep-water facies in the early Serpukhovian of SW Spain.</TITLE>
12969 <SOURCE>Facies 49, 1: 31-48.</SOURCE>
12970 <ABSTRACT>Large cyanoliths reaching up to 12cm in size and mainly prolate, discoidal and spheroidal in shape occur in early Serpukhovian rocks from the San Antonio-La Juliana Unit (Guadiato Area, SW Spain). The main component in the cyanoliths is Girvanella, but other important components are the problematic-algae Sparaphralysia, Calcifolium and crustose Fasciella. A diverse assemblage of invertebrates, algae and aoujgaliids also occur in the cyanoliths. The internal structure of cyanoliths shows discontinuous cortices with tabular and columnar growth of Girvanella domes, and bafflestones of Calcifolium. These cyanoliths were constructed in a quiet water, low-energy dysphotic environment, in relatively deep water facies, and on the upper part of the slope or deep outer shelf. The probably dominant factors necessary for their growth were bioturbation and gravity. The shape, size, architecture, depositional setting, multibiotic composition and lumpy

structure of these cyanoliths are similar to those of Cenozoic-Recent rhodoliths. Similarities to Osagia-type oncoids are few, and mostly related to the cyanobacterial composition. Only some Mississippian cyanoliths from Britain (digitate growth of cyanobacteria) and NW Spain and Poland (multibiotic composition) show notable similarities with cyanoliths from San Antonio-La Juliana. The San Antonio cyanoliths can be readily distinguished from coeval shallow-water oncoids in the Guadiato Area. [original abstract] </ABSTRACT>

12982 <SOURCE>Geologica Belgica 8, 1-2: 109-119.
<http://popups.ulg.ac.be/Geol/document.php?id=578></SOURCE>
12983 <ABSTRACT>A microbe-bryozoan patch-reef was temporarily exposed in the Lives Formation (middle Visean) at the Engihoul Quarry, southern limb of the Namur syncline. It developed within the Corphalie Member during the transition from bioclastic to stromatolitic facies. Reef formation is the result of a complex meshwork of calcified microbes, which formed complex layers which resemble "Osagia"-biocenose and individual columnar aggregates, fenestellid bryozoans, and early cements. Reef growth began on a hard- substrate provided by brachiopods and microbial crusts. Brachiopods (Composita sp.) are locally abundant in the reef facies, and contributed substantial firm ground for encrustation. Reef growth was controlled mainly by the abundance of fenestellid bryozoans. Their presence indicates reef formation during normal marine conditions. The reef developed in a high-energy area of the inner shelf. Reef growth probably stopped with the establishment of a peloidal mudstone facies, eventually indicating hypersaline conditions. The Engihoul reef is similar to Bome1 reefs (also in the Lives Formation). All are the same age and developed in the transitional phase of the Corphalie Member, but minor differences in the individual reef fauna occur. The transitional phase of the Corphalie Member is an important horizon for reef formation with clear independence from other reef forming episodes within the Belgian Dinantian succession.</ABSTRACT>

13009 <ABSTRACT>The 'Calcaires à Productus' of the Montagne Noire are
microbial build-ups. Two formations are defined and dated respectively
as Uppermost Viséan (Upper Warnatian-Brigantian) and Serpukhovian on
the basis on corals. That makes these limestones out to be younger than
previously stated (Lower and base of Upper Warnatian-Asbian and base of
Brigantian) and indicates that the development of the olistoliths and
thrusts including them, due to Variscan orogeny, was at least as young
as the Upper Serpukhovian. The Serpukhovian limestones of the Montagne
Noire are correlated with the Lanet Limestone (Mounthoumet Massif,
Corbières) and Ardengost Limestone (central Pyrenees).</ABSTRACT>

13020 <TITLE>Die Biokonstruktionen im Pennsylvanum des kantabrischen
Gebirges.</TITLE>
13021 <SOURCE>Kölner Forum für Geologie und Paläontologie 9: 1-139.</SOURCE>
13022 <ABSTRACT>The Pennsylvanian organic buildups from the northeastern
Cantabrian Zone (Pico de Europa Unit and Ponga Nappe) occur in
different topographic settings of a foreland basin with an adjoining
external carbonate platform during synorogenic to later orogenic
stages. They display spatial and temporal changes in biological
structure and organism association, distribution and morphology. Eleven
types are distinguished:1. Beresellid-chaetetid buildups, 2) chaetetid
biostromes, 3) coral-chaetetid reefmounds, 4) rugose corals meadows, 5)
Petchoria meadows, 6) phylloid algal boundstones, 7) Anthracoporella
mounds, 8) Archaeolithophyllum banks, 9)
bryozoan-pelmatozoan-brachiopod reefmounds, 10) pelmatozoan mounds and
10) sphinctozoan-algal boundstones.2. During the Moscovian the typical
Donetzella mounds of the Serpukhovian and Bashkirian were replaced by
equivalent shallow water communities of beresellid algae (Dvinella,
Beresella, Uraloporella), chaetetids and corals. Frequently, colonies
of syringoporids characterize the base, chaetetids the top of
shallowing upward-sequences. Relative small, typically "immature
" buildups and low-diverse biostromal and biohermal structures
reflect dynamic habitats due to sea-level changes.
Bryozoan-pelmatozoan-communities dominated especially in deeper water
environments. The platform slopes are stabilized by microbes and/or
pure or not calcifying organisms. Bioconstructing communities from the
Cantabrian Pennsylvanian in general have a low reef-building potential.
Early diagenetic cementation of the sediments is rare. Similarities
between North America and the northeastern Cantabrian zone concerning
the decrease of chaetetids at the unconform base of the Missourian (=
base of the Kasimovian) point to paleozoogeographic relationship, which
had been already observed in the coral fauna. Most benthic communities

are suppressed by siliciclastic and nutrient input. Archaeolithophyllum obviously tolerated such environments and built low diverse banks at the border of the carbonate platform, which episodically was influenced by deltaic deposition; thus these algal banks mark the progradation of the orogen. The bioconstructions of the mixed siliciclastic-carbonate sections of the Kasimovian are mainly dominated by algae. Especially Anthracoporella and Archaeolithophyllum are of great volumetric importance. The proof of widespread Anthracoporella mounds in the Cantabrian Mountains is of special interest because of the Palaeobiogeographic relations to the Anthracoporella mounds of the Carnic Alps. The decline of chaetetid dominated bioconstructions at the end of the Moscovian and the rise of algal dominated structures is a globally observed phenomenon. It coincides with an important floral change and, moreover, an important excursion of stable isotopes. Therefore, a global climatic change and associated changes of the carbon budget/nutrient input seem to be of first order importance for the reorganisation of the buildups. In </ABSTRACT>

13072 <TITLE>The occurrence of a microbial buildup at Poederlee (Campine Basin, Belgium): Biostratigraphy, sedimentology, early diagenesis and significance for Early Warnantian paleogeography.</TITLE>
13073 <SOURCE>Annales de la Societe geologique de Belgique 113, 2: 329-339.</SOURCE>
13074 <ABSTRACT>The Poederlee borehole is situated in the Campine Basin and has been drilled in the center of a domal structure at the top of the Viséan, identified by reflection seismic studies. The Viséan limestones in this borehole have an Early Warnantian (Late Viséan) age. They belong to the Carboniferous foraminifer 6<#947; subzone and to the rugose coral 7<#945; and β subzones. Two types of lithofacies, namely microbial boundstones and bioclastic packstones and grainstones, are present in these limestones. The first type represents the core of a reef mound, which developed below and near the wave base. The second type occurs above the boundstones, forms the flank and top facies of the reef mound and has been deposited above wave base. Five superimposed reef mounds have been recognized in the Lower Warnantian and are interpreted as a reef complex. A comparison of the Lower Warnantian reef mounds in the Campine Basin indicates that the paleogeographical position is a factor which influences their evolution. Diagenesis started with the precipitation of isopachous fibrous and fibrous radial calcites under oxidizing conditions in marine pore-waters. After the precipitation of the fibrous calcites, dissolution of these cements and of the host limestone possibly occurred in meteoric waters. Rim cements around crinoids and blocky calcites developed in a pore fluid which evolved from oxidizing to reducing.</ABSTRACT>

13085 <TITLE>Nouvelles données stratigraphiques et structurales sur le Dinantien dans l<#39;Avesnois.</TITLE>
13086 <SOURCE>Annales de la Société géologique du Nord 108: 125-142.</SOURCE>
13087 <ABSTRACT>Paleontology, sedimentology and tectonic fields are investigated. They allow a new paleogeographical approach of the western part of the Ardennes (Ardennes-area). The northern part contains Ivorian and Moliniacian facies with Waulsortian variations, they are similar to the <#34;Auge Dinantaise<#34; facies. * The southern part contains shallow water facies identical to those of Condroz area. A stratigraphic log is proposed using paleontological, sedimentological and lithological markers. Near Avesnes a wide quarry

- provides a tectonic model which can be applied to the Condroz area where outcrops are sparse. A detailed study of this quarry led us to a progressive deformation sequence, where narrow deformation bands follow wide less deformed bands. Regional shortening must have been accomodated by minor folding and slipping over many faults. [original summary]</ABSTRACT>

- 13113 <ABSTRACT>Six paleogeographic sedimentation areas (s.a.) are recognized in the Namur-Dinant Basin: (1) the Hainaut s.a., (2) the Namur s.a., (3) the Condroz s.a., (4) the Dinant s.a., (5) the Visé-Maastricht s.a., and (6) Avesnois s.a. (only in northern France). Together with the sea-level variations (third-order sequences), local controls influenced the nature of the sedimentary deposits, so the lithostratigraphic successions in each sedimentation area distinctive. The depositional setting was that of a carbonate platform which evolved from a ramp in the early Tournaisian to a rimmed shelf during the early Viséan and then to a regionally extensive shelf during the middle and late Viséan. Before the Livian, open marine facies were developed to the south, but from Livian onwards open marine facies were restricted to the north while evaporites developed in the south. This inversion of a normal pattern was probably related to an early phase of the Variscan shortening. Dinantian biostratigraphy is mainly based upon foraminifera, rugose corals and conodonts. Fifty formations (including members), 3 groups and 2 informal lithostratigraphic units are briefly described. [original abstract]</ABSTRACT>

- 13126 <ABSTRACT>The coral fauna of the European Zechstein (Werra cycle) is made up of only two species of Rugosa (family Polycoeliidae), Calophyllum profundum (Geinitz 1842), and Calophyllum quadrifidum (Howse 1848). Eleven additional taxa based on Zechstein materials are synonyms of these very variable species, as demonstrated by a rich collection of about one thousand specimens from 35 localities. A possible generic division between normal (Gerthia Grabau 1928) and ampleximorph polycoeliids (Calophyllum Dana 1846) would be premature. There are no Zechstein Tabulate, most old records now referring to Bryozoa. Corals lived everywhere in the Zechstein sea and are found both in near-shore and basinal regions. Other Rugosa communities, generally dominated by polycoeliids, from the Upper Permian of the boreal realm are reviewed. Relations are only indicated by striking similar species of Calophyllum from Zechstein sea, Kazanian sea, and eastern Greenland: Calophyllum profundum (Geinitz 1842), Calophyllum permianum (Nechayev 1894), Calophyllum permicum Fluegel 1973. Remarkable regional differences occur in Upper Permian Rugosa faunas of the palaeotethyan realm, too (Armenian assemblage of plerophyllids and southern Chinese Lophophyllidium-waagenophyllidae assemblage, both of lower Dzhulfian = Baisalian age).</ABSTRACT>

Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???
</SOURCE>
13191 <ABSTRACT>Stromatolites and laminated mats are characteristic of
Zechstein reefs which reach heights of 100 m. Bryozoans and other
macroscopic fauna are only additional attributes. Their baffling
effects are of minor importance. Reef-types vary from fringing and
barrier reefs to patch and pinnacle reefs. Occurrence and construction
of these reefs are very similar to those of modern coral reefs, mostly
depending on hydrodynamic conditions and the influx of siliciclastics.
Extensive reef-flats are controlled by sealevel. Macrofossils are
missing at the uppermost part of the reefs as a result of increasing
salinity. Very early marine lithification protected the buildups
against browsing and wave action, but pervasive dolomitization
destroyed the microstructures of reef-builders. Sealevel fluctuation
and changes in salinity are the most important parameters controlling
growth and termination of Zechstein reefs.</ABSTRACT>

- 13243 <ABSTRACT>This paper deals with the mode of occurrence, growth forms, skeletal preservation and the life conditions of some of the oldest, stratigraphically well-documented Anisian (Pelsonian-early Illyrian) scleractinian corals, occurring in situ, in shallow-water carbonate rocks in the Lower and Middle Muschelkalk of the Cracow-Silesian region, Southern Poland (northern Peri-Tethys, Central Europe). Among 18 species (from 14 genera; some of generic names require emendation), one of the important Anisian coral species is Pamiroseris silesiaca (Beyrich) (=former Thamnastraea silesiaca Beyrich), frequently occurring and widely distributed in the Peri-Tethyan (Germany, Poland) and found in the Tethyan provinces (Alps and S. China). The paper also presents skeletal growth bands of P. silesiaca and its septal microarchitecture, important because of high morphological homeomorphy of thamnasterioid corals e.g. Pamiroseris, Thamnasteria.</ABSTRACT>

- 13281 <SOURCE>Palaeoworld 19, 3-4: 382-388.</SOURCE>

- 13282 <ABSTRACT>Anisian scleractinian corals are known from the Lower and Middle Muschelkalk of the Cracow-Silesian region, but in bioherms they occur only in the western part, i.e., in the Upper Silesian area, in the higher part of the Lower Muschelkalk (Karchowice Beds). Silesian reefs of Anisian (middle Permian-early Illyrian) age are, so far, the oldest in situ coral reefs following the Permian / Triassic extinction. In Anisian time, Silesian corals formed a Tethys marginal reefal rim, separating offshore Tethyan open marine waters from the backreef area (Germanic Basin). The shallow-water coral-bearing facies capped sponge buildups, following a general shallowing trend in the basin. Final emersion in the early Illyrian halted coral reef growth. Anisian scleractinian corals appear to have been zooxanthellate, as suggested in Morycowa, 1988. [original abstract] </ABSTRACT>

- 13295 <ABSTRACT>The genus Eckastraea Morycowa, 1988 from the Middle Triassic of Cracow-Upper Silesian region has been created on the basis of the holotype of Isastraea prisca Weissermel, 1925. The systematical position of this genus was however, undetermined. The recent findings of better preserved specimens enabled to place the genus into the new family Eckastraeidae. This new family is closest to the family Margarophylliidae Cuif, 1977 belonging to the superfamily Volzeioidae suborder Caryophylliina.</ABSTRACT>

13332 <TITLE>Sponge / crinoidal / coral bioherms from the Muschelkalk of Upper Silesia (Middle Triassic, Poland).</TITLE>
13333 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 049-059.</SOURCE>
13334 <ABSTRACT>Sponge / crinoidal / coral bioherms have been found in the Karchowice Formation which is the uppermost lithostratigraphical unit of the Lower Muschelkalk in the Upper Silesian region. Taxonomic composition and biohermal structure show similarities to younger buildups, well-known during the Jurassic. Their lower part is made of primary lime mud with loosely packed clumps of siliceous sponges Hexactinoderma trammeri, accompanied by echinoderms, brachiopods, ecologically diversified bivalves, polychaetes, solitary corals, ostracos and foraminifers. In the middle part, sponges are successively replaced by encrinids, and infaunal bivalves disappear. In the upper part, both sponges and encrinids are replaced by corals (mainly Pamiroseris silesiaca) which form a rigid skeletal framework. Moreover, a significant increase in the number of species and individuals of herbivore gastropods is visible in this part of the bioherms, as well as the dominance of cemented and byssate bivalves. Such development of the biohermal structure can be referred to the shallowing of the sedimentary basin and to taphonomic feedback. Sponges (and other reef-builders) served as a substratum for the epifauna which was a source of skeletal hardparts. In this way, a hard substratum was originated, infaunal bivalves disappeared and the rigid coral framework developed. The bioherms developed at the edge of a shallow carbonate platform during regression of the Lower Muschelkalk sea. The coral community lived in shallow, euphotic water.</ABSTRACT>

13373 <ABSTRACT>Le bassin de Algarve a ete affecte par une transgression pendant l''Oxfordien moyen a laquelle s''est suivie une regression a partir de l''Oxfordien superieur. Au cours de cette periode regressive s''y sont installees des facies coralliques qui ont occupe de vastes surfaces surtout a Algarve oriental. L''installation de recifs de madreporaires a commence pendant l''Oxfordien superieur, le maximum etant atteint au Kimmeridgien inferieur. En meme temps a Algarve occidentale il y a eu des conditions qui correspondent a une mer peu profonde. Sur la cote occidentale actuelle (Carrapateira) se sont formes des biostromes de madreporaires qui ont occupe de vastes aires. Au cours de l''etape finale du Jurassique superieur la sedimentation a Algarve occidental a progressivement subi des influences continentales. A Algarve oriental, au dessus des recifs des madreporaires apparaissent des biostromes de polypiers a facies carbonatee ou marneuse, la formation de recifs n''etant plus possible.</ABSTRACT>

13385 <SOURCE>Estudios geol. 40: 455-461.</SOURCE>
13386 <ABSTRACT>The presence of coral colonies and oncoid facies in the Dogger of the External Subbetic is first shown in this paper. It is worthy of remark that the Dogger materials (oid limestones basically) are placed between pelagic formations. Really, they represent a part of a shallowing-upward sequence which begins with the pelagic sediments of the Domerian-Toarcian. Over these materials a shallow carbonate shelf is established where bioherms, coral colonies, oncoid and oid facies are developed, capping the sequence a hard-ground of the Upper Bathonian. The Upper Jurassic materials are clearly pelagic with ammonitico rosso facies. This work represents a contribution to the scientific controversy about the interpretation of the oid limestones of the Dogger. In other areas (Venetian Alps, Balearic Islands, etc.), these limestones have been interpreted as deep redeposited sediments and attempts to extend this interpretation to all the Dogger oid limestones of the Alpine realm have been made. The features shown in this paper about the shallow marine nature of these materials in the External Subbetic are conclusives.</ABSTRACT>

13411 <SOURCE>Palaeontographica A214, 3-6: 121-207.</SOURCE>
13412 <ABSTRACT>The Upper Jurassic marine strata in the northwestern Iberian Range and in adjacent areas have been studied by using sections from 78 localities. The main subjects of research are the coral-bearing beds of the Lower Kimmeridgian. A model of the palaeogeographical development is presented, with the northern epicontinental borders of the betic syncline in the Southeast and with the Jurassic Cantabrian basin in the North. The differentiated facies development proves the shallow character of this channel over the entire area. With only few exceptions the facies sucesion shows continuously open-marine

conditions which merely end just before the continental wealden sedimentation starts. Striking is the widespread occurrence of corals. Thick coralline limestones are to be found in the Sierra de los Cameros, the Sierra del Madero and the Noviercas-Ciria-Torrelapaja-Bijuesca-region. They generally indicate a decreasing sea-level in three steps: The initial stage is characterized by the flat colonies, especially by *Microsolena* settling in the different lithofacies. Even in sandy sediments and micritic limestones they are to be found, forming a widely extended biostromal slab up to 20 m in thickness. The following stage of differentiation shows a great variety, both in lithofacies and in the composition of coral faunas. A terminal stage with pebbly oolitic Chaetetid-limestones, originating from very shallow water, brings the marine development of the Upper Jurassic in the central part of the investigated region to an end. In spite of its shallowness and morphological impediments (reefs, oolite-and sandbars) permanent currents passed through the channel; otherwise the widespread coral growth and the complexity of the coral faunas could not have been developed. The palaeontology of the rich coral fauna from the northwestern Iberian Range is examined for the first time. The research is supplied by additional collections and investigations in the surrounding areas, mainly the Montes Universales, from where Geyer already has described a coral fauna. Altogether 1366 corals have been determined belonging to 49 genera with 96 species, including 7 new ones. The coral fauna described in part 1 is distributed to the families Actinastreaeidae, Amphiastraeidae, Cyathophoridae, Stylinidae, Euhellidae, Montlivaltiidae, Isastraeidae, Placosmiliidae, Faviidae and Dermosmiliidae. The voluminous fauna shows close connections to other Upper Jurassic coral occurrences in Central Europe, the Mediterranean and Caucasian areas, thus marginal domains of the Tethyan sea.

13424 <SOURCE>N. Jb. Geol. Palaeont. Mh. 1990, 10: 622-638. [in German, with English summary]</SOURCE>

13425 <ABSTRACT>The silicification of the corals of the Upper Jurassic of wuerttemberg (SW Germany) is described in regard to the different observed silica-phases. LS-chalcedony (quartzine) is the most common silica-phase; it occurs generally as a replacement of the neomorphic spar of the corals, rarely as a cavity filling. It is spherulitic and nearly always found beneath the surface of the corals, where it can form a skin. LF-chalcedony and megaquartz exist in corals only as cavity fillings, whereas megaquartz may occur in other shell fragments as a replacement. Microquartz is not too abundant and is only found as a replacement in micritic fillings of cavities between the septa of the corals. Lutecite was only found in echinoderm fragments, opale not at all. The aragonite of the coral skeletons was transformed into neomorphic spar in a marine environment. The Mg content of the neomorphic spar made the silica precipitate as LS-chalcedony, whereas in the adjacent cavities LS-chalcedony developed only initially but mainly LF-chalcedony and megaquartz. This is connected with an increasing burial under marine cover and concurrent decrease of the bulk pore-water in Mg²⁺ and SO₄²⁻ contents. As the sea retreated from

- the area of the Swabian Alb after the Lower Tithonian, the silicification has to be supposed to be of early Tithonian age. The silicified areas were submitted to beginning recalcitisation.

13437 <SOURCE>Palaeontographica A226, 4-6: 77-123.</SOURCE>
13438 <ABSTRACT>During Late Oxfordian and Middle Kimmeridgian (Late Jurassic), small patch reefs were formed at numerous localities in northern Germany. The richly structured neritic sea was characterized by seasonally varying environmental factors, such as water movement and illumination as ecological requisites, and sedimentological conditions and bioerosion as ecological addends. These factors evidently affect the faunas. Thus, palaeontological facies interpretation is possible according to qualitative and quantitative criteria supported by sedimentological results. Twenty six species of reef corals are described in detail and arranged in various guilds (builders, bafflers, binders, dwellers) on the basis of the impact of growth forms on the skeletal frame. However, intraspecific variation of guild membership may occur due to different reefal architecture. The most important synecological parameters, dominance and diversity, are calculated for all localities. *Thamnasteria concinna* (Goldfuss) which can tolerate partial mortality well is the dominant species in various environments, thus showing ubiquitous characteristics. The diversities of the associations examined are generally low and strongly vary within comparable facies. These facts prove the oscillation of important environmental factors. Despite the ecological preferences of some taxa, the distribution of reef corals seems to be mostly random, at least in more favourable environments. [list of species: *Actinastrea pentagonalis* (Muenster 1829), *Cyathopora* (C.) *bourgueti* (Defrance 1826), *Convexastrea sexradiata* (Goldfuss 1829), *Sfyliina* (S.) *limbata* (Goldfuss 1826), *Styliina* (S.) *delabechii* Edwards & Haime 1851, *Goniocora socialis* (Roemer 1836), *Cladophyllia dichotoma* (Goldfuss 1826), *Heliocoenia variabilis* Etallon 1859, *Montlivaltia obconica* (Muenster 1829), *Thecosmilia trichotoma* (Goldfuss 1826), *Th. costata* Fromentel 1861, *Latiphyllia suevica* (Quenstedt 1858), *Isastrea crassa* (Goldfuss 1826), *I. helianthoides* (Goldfuss 1826), *Placophyllia minima* Geyer 1955, *Microsolena agariformis* (Etallon 1859), *Thamnasteria concinna* (Goldfuss 1826), *Th. seriata* Becker 1875, *Calamophyllia disputabilis* (Becker 1875), *Dermosmilia? nana* (Roemer 1836), *Latomeandra plicata* (Goldfuss 1826), *Ovalastrea michelini* (Edwards & Haime 1851), *O. caryophylloides* (Goldfuss 1826), *Microphyllia brevivallis* (Becker 1875), *M. seriata* (Becker 1875), *Actinaraea granulata* (Muenster 1829)]</ABSTRACT>

- 13450 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 143-160.</SOURCE>
- 13451 <ABSTRACT>The studied reefs are situated around the Cameros Basin (Late Jurassic-Early Cretaceous; North Spain) in a rim of marine Jurassic outcrops. The last marine Jurassic sediments in the area are characterized by the development of coral reefs which correspond to the Kimmeridgian. These reefs were situated in an epicontinental seaway which lay between the Iberian and Ebro massives. This sequence is best exposed near Torrecilla en Cameros where a fringing reef has been identified. In each buildup of this reef complex, the reef-core, with a fore-reef and long-shore carbonate sand bars can be distinguished. The reef complex in Soria has a different geometry for vertical growth dominates, although some progradation occurs and a back reef grainstone facies prograded over the core reef facies. Many diagenetic processes have affected these reefs although cementation is particularly important because it has provided a clear paragenetic sequence related to the diagenetic evolution of these limestones. The most common sequence evolves from submarine cements (only present in primary cavities) to cements precipitated under active fresh-water phreatic conditions, stagnant phreatic afterwards, and finally under burial conditions. This sequence represents progressive burial of these reefs when a very thick series of essentially continental sediments was deposited. Another less common sequence is present in some dissolution cavities generated in the subsurface. This sequence evolved from cements precipitated in a reduced environment to shallower oxidizing ones precipitated under telodiagenetic conditions.</ABSTRACT>

- 13464 <ABSTRACT>Coral associations occur in situ within fine-grained siliciclastics in the Oxfordian (Late Jurassic) of northern Germany. Compared with contemporaneous localities representing other environments, their diversity was slightly lower; species tolerating sedimentation were more important. The morphology of their coralla with large well-integrated calices and strongly ornamented septa was flat, resulting from reduced light levels; no branching forms occur. Terrigenous clastics reached the areas of coral growth seasonally during times of increased runoff in a warm-temperate climate, probably without being fenced off somehow. Corals show strong partial mortality but were able to recover by overgrowing the sediments. Since coral surface was quickly covered unless living polyps removed sediment continuously, encrusters and borers found hardly any suitable substrate; their abundance in the associations was very low therefore.</ABSTRACT>

13488 <TITLE>Upper Jurassic coral communities within siliciclastic settings (Lusitanian basin, Portugal): implications for symbiotic and nutrient strategies.</TITLE>
13489 <SOURCE>Proceedings of the 8th International Coral Reef Symposium Panama City 2: 1755-1760.</SOURCE>
13490 <ABSTRACT>Upper Jurassic coral communities of Portugal (Lusitanian Basin) grew despite high siliciclastic influx. Small, reef-rimmed carbonate platforms existed on basement uplifts over an extended period of time. Other reefs grew whenever episodes of tectonic quiescence and/or rising sea level reduced siliciclastic influx. Reefs grew within a coarse siliciclastic fan delta and on a fine grained, siliciclastic slope system. The latter is developed as a distally steepened mixed carbonate-siliciclastic ramp system, which provided excellent examples for constantly or periodically sediment-stressed reefs. Sedimentation rather than water depth was the major modifier of diversity of coral communities and coral growth forms. For example, massive to foliose *Microsolena agariciformis* changed to a *pseudobranched* morphology composed of thinly stacked encrusting layers during elevated sedimentation. Depth distribution patterns and morphologic changes clearly show that Jurassic hermatypic corals had photosymbionts. However, their frequent occurrence within, or very close to, siliciclastic settings indicates that they could tolerate higher nutrient rates than modern reef corals, probably because of a still imperfect symbiotic relation. Consistent with this interpretation are the slower growth rates and the lower low to high density band ratios of Upper Jurassic reef corals even in very shallow, non sediment-stressed reef settings.</ABSTRACT>

13503 <ABSTRACT>New data since the synthesis of Fabre et.al. (1982) concerning the fossil locality of Canjuers (Var, France) are provided. Many species are added, mainly among plants, corals, brachiopods, ammonites and echinoderms. The species previously reported are

- re-examined. The early Tithonian age, mucronatum zone (and not Berriasian as formerly presumed) of the fossil locality is based on ammonites. Flora and fauna are close to the nearly contemporaneous fossils from the lithographic limestones of Bavaria and, with fewer affinities, to those of Cerin (Ain).</ABSTRACT>

- 13516 <ABSTRACT>The Upper Jurassic coral assemblages of the Holy Cross Mts. and Polish Jura Chain are composed of: a) foliaceous and submassive colonies, b) branching colonies and c) massive subspherical colonies. The character of corals and associated fauna and flora, as well as deposits in which the assemblages occur indicate a very shallow-water environment. The character of this environment and the process of sedimentation, which accompanied the growth, indicate i.a. that the assemblages were formed by the accretion of colonies at a rate equalling that of the sedimentation. An increase in the rate of sedimentation caused the end of their development. The assemblages discussed did not supply detrital material to the sediment and did not exert a decisive influence on the course of sedimentation, which makes them similar to Recent patch reefs of the Bahamas.</ABSTRACT>

- 13555 <ABSTRACT>Coral biostromes from the Camarena Formation (External Subbetic, Betic Cordillera) are reviewed under palaeoecologic, taphonomic and palaeontologic aspects. The biostromes are dominated by phaceloid forms and are characterised by a typical shallow-marine microencruster assemblage with photophilic microencrusters and scarce microbial crusts. The abundance of stylinid corals and light-dependant microencrusters suggest oligotrophic conditions. Coral colonies were located among oolitic shoals which were unfavourable for coral growth. The corals were developed in phases without oolitic production alternating with phases of oolitic production, forming metric-scale sequences. A relative sea-level fall would have reduced the ooidal production and led to the deposition of thin layers of micritic facies in intertidal areas. The cementation and hardening of the bottom resulted in a hardground that was colonized by corals after a subsequent relative sea-level rise. The progressive increase of the energetic conditions induced an increasing production of ooids and the migration of oolitic shoals, which covered and finished the coral biostromes. Repetition of this process gave rise to sequences reflecting small pulses of oscillations in the relative sea level. [original abstract]</ABSTRACT>

13581 <ABSTRACT>Subject of the work are corals as substrate and center of activity of various organisms. The material dealt with comes from 12 localities in at least six stratigraphic positions in the northern German Upper Jurassic (Oxfordian and Kimmeridgian). Ten species of corals have to be considered in this context, their measurable surfaces summing up to more than 6.4 qm. (The other 24 species of scleractinians in the region are not examined because of their relative insignificance in ecological terms.) This area reveals some 80 different taxa with about 20.500 individuals altogether. [first part of extensive summary]</ABSTRACT>

13594 <ABSTRACT>The environmental conditions during the growth of Upper Jurassic coral reefs Northeast France and Southwest Germany were reconstructed by the detailed analysis of the reef fauna and sedimentological criteria in comparison with modern coral reef environments. The ecological interpretation of all exposed reef bodies in this regions makes up the base for the reconstruction of the local and regional environment. While the Oxfordian reefs of Lorraine and the Isteiner Klotz were situated on an extensive and low relief carbonate ramp, the comparatively small platform reef of Arnegg developed on a submarine shallow during the Kimmeridgian. For the comparison of a multitude of structurally different coral reef types in different time sections a new reef classification was worked out. This classification is based on ecological meaningful and exactly defined faunistical and structural features of the reef body and facilitates the comparison of different reef bodies, reef types and over geological time periods. As the determining physically-chemical factors for reef growth light, sedimentation rate, oxygen- and nutrient content, temperature and salinity could be worked out which secondarily were influenced by the topography of the seafloor, the substrate consistence and the position of the reefs on the shelf profile. In all examined sequences the succession of coral faunas and reef types documents a shallowing upwards. The onset of coral reef growth is generally caused by the lowering of sedimentation rates: for the Oxfordian reefs because of a global transgression - for the Kimmeridgian Arnegg platform because of an elevated structural position. Increasing sedimentation rates during the following sea-level highstand (Oxfordian reefs) and relief compensation (Arnegg platform reef) were finally leading to the killing of coral growth. 13605 <TITLE>Growth models of Bajocian coral-microbialite reefs of Chargey-les-Port (eastern France): palaeoenvironmental interpretations.</TITLE>
13606 <SOURCE>Facies 52, 1: 113-127.</SOURCE>
13607 <ABSTRACT>Very large amount of microbialites, up to 70% of the reef volume takes part in the edification of Lower Bajocian coral reefs in the Chargey-les-Port quarry (Haute-Saône, France). Such high amounts of microbialites were unknown within bioconstructions of Middle Jurassic age. Along the 16 m-thick section, seven successive biohermal or biostromal units developed on a shallow platform. Bioconstructions display a first coral growth phase with either constrictal or superstratal growth fabrics. Coral fauna is relatively poorly diversified and is dominated by massive forms (*Isastrea*, *Thamnasteria*, and *Periseris*) or branched phaceloid (*Cladophyllia*) and ramose (*Dendraræa*) colonies. Corals can be heavily encrusted by microbialites of diverse forms and fabrics (leiolitic, thrombolitic, and stromatolitic). According to the coral growth fabrics, microbialite crusts developed on top of or at the underside of coral colonies, forming a coral-microbialite elementary unit. Microbialites show a multiphase development: (i) directly at the coral surface, a first and mm-scale microbialite layer locally developed; (ii) a second, cm-scale microbialite layer (up to 8 cm thick) covered the entire coral reef framework and assumed the main building role; and (iii) a third, mm- to cm-scale, laminated microbialite layer may also be observed overlapping previous reef structures, before having been progressively buried under sediments. Contemporaneously to the coral growth phase, the first microbialite layer developed on dead portions of coral colonies. The transition between coral growth and microbialite development (i.e., second layer of microbialites) is interpreted as a result of a coral reef crisis, probably reflecting more nutrient-rich conditions. The passage to a stromatolitic (third) layer suggests a control of the accumulation rate. Composition and architecture of coral-microbialite reef units of Chargey-les-Port highlight the relations between high-frequency fluctuating environmental factors (mainly accumulation rate and trophic conditions) and reef development.</ABSTRACT>

" dans le Jurassique supérieur du Portugal.</TITLE>
13645 <SOURCE>Geobios 38, 5: 653-666.</SOURCE>
13646 <ABSTRACT>From the Kimmeridgian (Upper Jurassic) of Portugal, the
coralline sponge Sobralispongia densespiculata nov. gen. and nov. sp.
is described. Main characteristics are a crustose habit, a primary
spicule skeleton of very densely packed styles and subtylostyles
arranged in a plumose architecture, microscleres of possibly
aster-type, and a microgranular to fibrous secondary calcareous
skeleton. The primary mineralogy of the calcareous skeleton was
probably high-Mg calcitic. An assignment to the demosponge Order
Axinellida is proposed.</ABSTRACT>

13657 <TITLE>Comparative palaeoecology of marly coralline sponge-bearing
reefal associations from the Kimmeridgian (Upper Jurassic) of Portugal
and Southwestern Germany.</TITLE>
13658 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester
P. (ed.) Proceedings of the VI. International Symposium on Fossil
Cnidaria and Porifera, vol. 2]: 381-397.</SOURCE>
13659 <ABSTRACT>Three marly reefal associations from the Kimmeridgian of
Portugal (Alcobaca, Serra Isabel) and southwestern Germany (Faulenhau),
which share a high proportion of coralline sponges as a main unifying
element, were studied in a comparative manner. The two Portuguese
associations are dominated by corals and coralline sponges (Alcobaca),
and by crinoids and corals (Serra Isabel), respectively. Both
sedimentological and palaeoecological analysis evidence a very shallow
environment at Alcobaca and a deeper slope setting at Serra Isabel. The
association at Faulenhau, occurring within the sponge mound fades of
Southern Germany, is dominated by hexactinellid and lithistid siliceous
sponges, but contains an unusually high proportion of coralline
sponges. Comparison of the three associations allows the establishment
of bathymetric gradients and enables interpretation of the somehow
enigmatic association at Faulenhau. All three associations grew in a

fully marine, low-energy, low-sedimentation environment. The compositional differences are due to increasing bathymetry (presumably Alcobaca less than 20 m, Serra Isabel 50–60 m, Faulenhau 70–90 m). This is well reflected only at the generic and species level, where several taxa from various groups (coralline sponges, bivalves, microbes and microproblematica) are stenobath, whereas many others are not. The main trends towards deeper water are decrease in the diversity of corals, coralline sponges and *algae*; increase in the diversity of siliceous sponges, change in the composition of encrusting bivalves, and decrease in the activity of boring bivalves. Changes in morphotypes and dominance of guilds occur among corals, sponges and bivalves, but are only partially helpful in discriminating environmental differences. Bathymetric change is commonly, but not necessarily correlated with a change in nutrient and oxygen levels. Partial decoupling of these factors is obvious at Serra Isabel, where siliceous sponges are, at a cm-scale, replaced upwards by a hermatypic coral-crinoid association. However, the dominance of sponges at Faulenhau cannot be explained solely by slightly increased nutrient levels, since the diversity of coralline sponges is much lower than at Alcobaca and Serra Isabel. It is expected that the bathymetric position of the majority of the Upper Jurassic sponge-crust mounds grew in water deeper than for the Faulenhau example, i.e. below 70–90 m, although siliceous sponge facies could have occurred at lower depths in regions or at times of lowered oxygen contents or slightly increased nutrient levels, e.g. during rapid sea-level rise.

 13683 <TITLE>Coraux constructeurs du Bajocien inférieur de France. 1ère partie.</TITLE>
 13684 <SOURCE>Geobios 33, 1: 51–72.</SOURCE>
 13685 <ABSTRACT>Lower Bajocian (Propinquans and Humphriesianum) reef-building corals of France are rather poorly diversified: 16 to 19 genera (including morphogenera) and 17 to 26 species. The new genus *Atelophyllia* is created and the poorly known genus *Ebrayia* is revised. Synonymies of species are well understood, owing to a statistical analysis of populations sampled in the field (1410 samples, 900 thin sections). The taxonomic list and statistics offer first paleogeographical tool to study the trends of diversity. Because this diversity increases southwards (South Jura, Maconnais), it suggests that a climatic control underlies the diversity gradient. Functional

morphological analysis of various taxa offers a second method to evaluate ancient light intensities and sedimentation rates. For instance, a comparison with *Montastrea*, a recent zooxanthellate coral, shows that the variations of the colonial shape of *Isastrea* are light-dependant. An interpretation of Bajocian bioherms as lithoherms built by nonzooxanthellate corals must be rejected. The average annual growth rates of Bajocian corals are very low. The new findings suggest evolutionary and climatic explanations. </ABSTRACT>

13696 <TITLE>Analyse de populations d'Isastrees bajociennes (Scleractiniaires jurassiques de France). Consequences taxonomiques stratigraphiques et paleoecologiques.</TITLE>
13697 <SOURCE>Geobios 21, 3: 269-305.</SOURCE>
13698 <ABSTRACT>The present statistical study of two Bajocian populations of *Isastrea* from eastern France uses different methods of measurement taking into account the colonial character. The results of the univariate and the multivariate analyses together with direct observation of qualitative characters show that only two species are present in the samples: *Isastrea bernardiana* and *I. tenuistriata*. A new synonymy is suggested for the Bajocian species. Genera such as *Andemantastrea* Alloiteau and *Parisastraea* Alloiteau correspond to the common variation of *Isastrea*. The taxonomic position of other Jurassic *Isastrea* is examined. It is probably possible to use extreme morphotypes as stratigraphic markers owing to an eventual anagenesis. A comparison between the two samples denotes that the variation range or the mean value of some quantitative characters (number, thickness of septa, dimension of corallites, trabecular density) contributes to the paleoecological interpretation. The present paper emphasizes the necessity of well-defined species based preferably on population study, for a reliable generic definition.</ABSTRACT>

13723 <SOURCE>C. R. Acad. Sci., Paris 308, ser. II: 887-892 [en francais avec abridged english version].</SOURCE>
13724 <ABSTRACT>Isastrea, a mesozoic genus of Scleractinia usually shows a massive form and a cerioid colonial structure. Samples from the Bajocian of Lorraine (France) demonstrate for the first time that the corallum can be branching and phaceloid. This structure is interpreted as the result of a partial death of the colony.</ABSTRACT>

13749 <SOURCE>Paläontologische Zeitschrift 63, 3-4: 193-205.</SOURCE>
13750 <ABSTRACT>Development and growth of Upper Jurassic colonial corals Actinastrea matheyi from Portugal was ruled by abiotic factors (water energy, sedimentation rate) and biotic factors (predation and parasitism). Phases of growth were interrupted by high energy events which caused tilting of the corals. In addition, intensified parasitism and predation occurred.</ABSTRACT>

13761 <TITLE>Periseris: scleractiniaire colonial jurassique. Revision structurale et taxinomie de populations bajociennes de l'Est de la France.</TITLE>
13762 <SOURCE>Geobios 23, 1: 10 pp., 6 pls.</SOURCE>
13763 <ABSTRACT>For a long time, Periseris Ferry 1870 (Jurassic scleractinian) has been confused with Thamnasteria Lesauvage 1823, in spite of their different septal morphology. A new diagnosis of the

genus, a specific redefinition using a numerical population approach and an illustration of the type species, *Periseris elegantula* (d'Orbigny) are given here. The studied colonies have been collected at several Bajocian outcrops in Eastern France. The data used consist of measurements of the distance between corallite centers, the corallite density, the number of septa, the septal density, the trabecular density, the pennular width, the trabecular width and the vertical distance between pennulae. Direct observation of qualitative characters, univariate analyses and principal component analysis suggest the presence in the samples of one single variable species: *Periseris elegantula*. Discriminant analysis shows that outcrops are well explained by the variations of characters. These variations are ascribed to an environmental origin. Among Middle Jurassic species, 14 junior synonyms have been enumerated. [communication presentee au premier congres national de l'association paleontologique francaise: Paris, 17-20 mai 1990]

 13776 <ABSTRACT>The palaeontology of the rich coral fauna from the Northwestern Iberian Range is examined for the first time. The research takes into account additional collections of surrounding areas as well, for instance from the occurrences of the Montes Universales, previously described by Geyer (1965). The determined corals are distributed to 49 genera with 96 species, 7 new ones among them. The second part submitted contains 3 of these new descriptions. The portion of the fauna dealt with in here includes the families Rhipidogyridae, Haplaraidae, Actinacididae, Thamnasteriidae, Latomeandridae, Synastraidae and Microsolenidae.</ABSTRACT>

13878 <TITLE>Die Korallenfauna des Korallenooliths (Oxfordium, Oberjura, NW-Deutschland): Zusammensetzung, Stratigraphie und regionale Verbreitung.</TITLE>
13879 <SOURCE>Paläontologische Zeitschrift 77, 1: 77-94.</SOURCE>
13880 <ABSTRACT>The stratigraphic and regional distribution of the Oxfordian scleractinian reef corals in the Korallenoolith Formation (NW German Malm Group) is described from the Suntel, Deister, Kleiner Deister and Osterwald Mountains. In the study area four horizons with (par-)autochthonous corals are developed two of which can be traced region-wide (Untere Korallenbank Member and florigemma-Bank Member / Obere Korallenbank Member). * The coral fauna of the biostromes, forming the Untere Korallenbank Member, is impoverished and dominated by ubiquitous r-strategists. In contrast, the reefal bioconstructions of the florigemma-Bank Member show a high variability in their regional appearances, partly forming highly diverse coral associations. The highest diversity is developed in the patch reefs from the Obere Korallenbank Member of the Osterwald Mountains (about 40 species). *

Corals are an important part of the Korallenoolith fauna. Altogether 20 species belonging to 15 genera have been identified which were formerly unknown from NW German Oxfordian successions. [original abstract]

13905 <SOURCE>Geobios 29, 5: 577-603.</SOURCE>

13906 <ABSTRACT>A population study has been carried out on Bajocian montlivaltiid corals. Some colonies determined as *Complexastrea* come from reef-building environments; others, non reef builders, were collected from the outcrop of Denney and display all the transitional morphological steps between the genera *Montlivaltia*, *Coenotheca*, *Latiphyllia*, *Complexastrea* and *Thecosmilia*. A statistical study shows an unimodal distribution of usual quantitative specific characters, a comparable mean for reef building and non reef building forms but a larger variability range for non builders. Discriminant analysis does not allow to separate infallibly these two sets. Both are put in a common specific, transgeneric, taxonomic unit through use of the spectral nomenclature. The study of serial sections confirms the non-reef building population as corals stopped at a young phase of their astogeny. This kind of populations is not exceptional in the Jurassic, probably controlled by the unstable nature of the substrate. Relatively to evolutionary patterns, it is impossible at present to consider the cited genera as being phyletic. Several alternative hypotheses are proposed, among which, some renew our vision of this group, emphasizing the iterative production of generic morphologies explained by the hypothesis of heterochronic process. The study of the microarchitecture demonstrates that the laminar layers of the septa in montlivaltiid corals are in full continuity with the dissepiments of the endotheca. Their geometry supports the idea of a genesis of dissepiments linked to a rising of the soft body.</ABSTRACT>

13919 <ABSTRACT>[Description of Thecomeandra nov. gen. from Tithonic beds of Stramberk (Moravia). This genus differs from other meandroid genera of Montlivaltiidae by a septothecal wall and lamellar linkages between centers.] En étudiant les coraux des calcaires Tithoniques de Stramberk (Moravie) j'ai trouvé parmi eux un nouveau genre de la famille Montlivaltiidae, que j'ai nommé Thecomeandra. Diagnose: polypier colonial, massif, méandroïde, présentant des séries calicinales séparées par des collines tectiformes continues, sans ambulacres. Rares calices isolés. Les calices dans les séries sont reliés par des septes de vallée. Les costoseptes entre les séries ne confluent pas, ou apparemment seulement, formant par leurs extrémités périphériques une septothèque. Dissepiments abondants, subhorizontaux ou obliques. Bourgeoisement intracalical. Le nouveau genre ne comprend qu'une espèce, T. remesi n.sp. Affinités: Le genre nouveau diffère des autres genres méandroïdes de cette famille surtout par la muraille septothécale et les septes de vallée.</ABSTRACT>

13931 <SOURCE>Berliner geowissenschaftliche Abhandlungen E13: 397-417.</SOURCE>
13932 <ABSTRACT>In the uppermost facies of the Oxfordian / Kimmeridgian " Korallenoolith" of Oker small lagoonal patchreefs are present. They are constructed of exogyrid oysters, serpulids, and large single scleractinians. Framebuilding algae are absent. The surrounding sediments were stable soft bottoms with large numbers of nerineid gastropods and semi-infaunal bivalves. Dasycladacean algae are rarely present. Within small caves, empty conches of exogyrids, and inter biogene spaces settled a large number of cryptic sponges (mainly tetractinellid demosponges). Caused by bacterial ammonification part of the sponge soft tissues were altered in automicrite. Therefore the sponge skeletons exhibit more or less their entire shapes. Beside this type of automicrite stromatolitic and thrombolitic microbialites play an important role in stabilizing the patchreef frame.</ABSTRACT>

- 13958 <ABSTRACT>Spongiolitic facies occurs widespread in the northeastern part of the Iberian Chains, spanning the humphresianum to parkinsoni zones of Bajocian age. The study area extends from Chelva in the South to Ricla in the North (provinces of Valencia, Teruel and Zaragoza). Spongiolite development include biostromes and bioherms which overlies a generally regressive succession of bioclastic limestones punctuated by occasional hardgrounds. Spongiolite development was surrounded by coeval biomicritic or ooid-bearing detrital limestones. Spongiolites of the humphresianum zone are dominated by hexactinosan (dictyid) porifera, brachiopods and bivalves, whereas ?;lithistid?; demosponges and crinoids are the predominant elements of the superimposed spongiolites of the parkinsoni zone. Glauconite grains and layered to nodular siliceous concretions are abundant within the spongiolites. Clear differences in faunal composition exist between firm bottoms (on frequent hardgrounds as well as within bioherms and biostromes) and soft bottoms (in evenly bedded limestones and intermound areas). Firm bottom communities are composed of sponges, brachiopods (rhynchonellids, Septaliphoria ssp, Loboidothyris ssp.) limid and pectinid bivalves, gastropods (Pleurotomariacea, Trochidea, Loxonematacea, Naticacea and Muriacea) regular echinoids, crinoids, ?;algae?;, serpulids, bryozoans as well as a distinct spectrum of foraminifers characteristic of sponge facies. Soft bottom communities comprise sponges (rarely in life position), brachiopods (rhynchonellids, Tetrarhynchia ssp., Lobothyris ssp.), burrowing bivalves (Myophoriidae and Pholadomyidae), rare gastropods, irregular echinoids and foraminifers which are clearly different from the sponge facies. The spatial arrangement of different lithofacies and biofacies is characteristic of an ecologically / bathymetrically and sedimentologically differentiated ramp. Spongiolites only developed in selected areas with optimum condition. Towards East and west spongiolite facies is substituted by oolitic bioclastic limestones of higher energy settings. During the late Bajocian changing environmental conditions resulted in a retreat of sponges from the Celtiberian region.</ABSTRACT>

13995 <TITLE>Ecology of sponge reefs from the Upper Bathonian of Normandy.</TITLE>
13996 <SOURCE>Palaeontology 24, 1: 1-23.</SOURCE>
13997 <ABSTRACT>Platychnonia magna (d'Orbigny), a lithistid sponge previously regarded as a calcisponge (Cupulospongia magna) forms small bioherms in rocks of Upper Bathonian age (sub-zone of Clydonioeras hollandi) at Saint-Aubin-sur-Mer on the Normandy coast. In addition to the main frame-builder, four subsidiary faunal groups are preserved. These are: (i) encrusting organisms which attached to the sponge fronds and gave the reef additional strength: (ii) byssate and pedically attached filter-feeding nestlers; (iii) vagile strollers which predated, scavenged, or grazed; (iv) borers. The encrusters may be further subdivided into a low diversity assemblage on the upper sides of the Platychnonia fronds, and a high diversity assemblage on their undersides. The reefs are envisaged as having grown in the lower photic zone, below normal wave-base but above that reached during storms. The fauna and habitat of the reefs are compared with those of Upper Jurassic lithistid sponge reefs in southern France and Germany, and with those of Middle and Upper Jurassic sponge accumulation in Great Britain. * The Platychnonia magna fronds underwent early diagenetic loss of their original hyaline silica skeleton, together with early lithification of the fine sediment which permeated their canals after death. This appears to be a common occurrence in fossil lithistids.</ABSTRACT>

14008 <TITLE>An Upper Jurassic sponge-algal buildup from the northern Frankenalb, west Germany.</TITLE>
14009 <SOURCE>SEPM Special Publications 30 [D.F. Toomey (ed.): European Fossil Reef Models]: 371-397.</SOURCE>
14010 <ABSTRACT>During Upper Jurassic time (middle-upper Oxfordian) a number of relatively small organic buildups, principally composed of siliceous sponges and algae, developed in the area of southern Germany. This study concentrates on one of these organic structures, the Mlllersfelsen buildup (northern Franconian Alb near Streitberg). It is demonstrated that the dominant buildup constructional organisms are siliceous sponges, principally of two morphologies (cup-shaped and dish-shaped forms), and cyanophycean algae, which aided in forming the mound configuration. * The Mullerfelsen buildup developed during several cyclic stages which occurred in relatively deeper water subtidal depositional environments, without strong current and wave actions. Three facies types have been recognized, these are: (1) sponge-crust boundstone facies characterized by micritic bound-stone rich in calcified siliceous sponges, tuberooids, and crusts; (2) lithoclastic packstone facies in which spheroidal sedimentary particles (lithoclasts, tuberooids, and bioclasts) are the dominant grain-supported allochems; and (3) tuberolitic wackestone facies in which mud-supported sedimentary particles are dominant. * The spatial distribution of these microfacies indicate that the sponge-crust boundstone facies is the mound constructional facies, whereas both the tuberolitic wackestone and packstone facies are only developed in those areas marginal to the main organic buildup. The uppermost portion of the Mullerfelsen buildup is dolomitized. [original summary]</ABSTRACT>

14022 <SOURCE>Bulletin de la Societe geologique de France 172, 5: 637-647.</SOURCE>
14023 <ABSTRACT>The Upper Liassic series in the western border of Iberia (Lusitanian Basin, Portugal), show an important lutitic sedimentation, characterized generally by a monotonous marl/limestone alternation. Small scale siliceous sponge mudmounds occur in these deposits from Middle Toarcian to Lower Aalenian age. The scope of this work is to pinpoint the stratigraphical and sedimentological context and to characterize controlling factors of the spongioliths. [initial fragment of extensive summary]</ABSTRACT>

14034 <TITLE>Kieselschwamme als potentielle Indikatoren fuer

- Sedimentationsrate und Nährstoffangebot am Beispiel der Oxford-Schwammkalke von Spanien.</TITLE>
- 14035 <SOURCE>Profil 8: 281-304. [in German, with English abstract]</SOURCE>
- 14036 <ABSTRACT>The siliceous sponge fauna of the Oxfordian spongiolites of eastern Spain clearly demonstrates that the shape of morphovvariable sponges as well as the taxonomic composition of morphoconstant sponges precisely mirrors external environmental factors. Richness of hardgrounds, automicrites and glauconite, very reduced sediment thicknesses as well as overall character, abundance, low diversity and uniformity of benthic fauna over a minimum area of 75000 qkm suggest a moderately deep, uniform low-energy ramp setting with extremely reduced carbonate and terrigenous background sedimentation. The very reduced influx is interpreted to have resulted in a very low nutrient level, which is reflected by a strong reduction in filter-feeding organisms such as bivalves, crinoids, brachiopods or serpulids frequent in other Late Jurassic sponge settings. The sponge fauna itself is characterized by the almost exclusive occurrence of a uniform low-diversity, specimen rich fauna of hexactinosan dish-shaped sponges, uncommon in most other Late Jurassic sponge faunas. These observations indicate that the major factors controlling the morphological and taxonomic composition of siliceous sponge faunas are sedimentation rate and food supply. When food is available filter-feeding sponges live on free bacteria. The mesohyl of these sponges shelters a rich microflora of symbiotic bacteria. At low nutrition rates two different strategies are developed. Demosponges enlarge their mesohyl so that more bacteria can be stored during times of reduced food supply. In morphoconstant demosponges, this strategy results in a thickening of the sponge walls in order to increase the available volume. Morphovvariable sponges are able to completely change their form and will preferably develop thick knob-like or tube-like morphologies. [part of extensive summary]

- 14061 <SOURCE>Zeitschrift der Deutschen Geologischen Gesellschaft 153, 2/4: 159-186.</SOURCE>
- 14062 <ABSTRACT>Based on microfacies analysis, the sedimentary succession of the Korallenoolith Formation cropping out in the Hainholz limestone quarry in the Osterwald Mountains has been studied. The 42m thick

deposits almost completely represent the Korallenoolith Formation in the Osterwald Mountains and allow the subdivision into three lithological units: the section starts with (1) the Ahrensberg Member, a 26m thick succession with an alternation of oolitic bioclastic limestones and marls at its base that swiftly grades into a monotonous oolite sequence. It is separated from (2) the overlying Hainholz Member ("Obere Korallenbank" of Hoyer 1965) by a prominent erosional unconformity. The Hainholz Member represents reefal deposits 12m in thickness. It is followed by (3) an unit of quartz-bearing calcarenite vertically grading into oolite, and cortoid limestone upsection, the Barenburg Member. Although the Korallenoolith Formation is traditionally subdivided into three (litho-) stratigraphical subunits ("Unterer Korallenoolith", "Mittlerer Korallenoolith", and "Oberer Korallenoolith", see Schulze 1975), they cannot be equated with the tripartite lithology of the studied section. According to comprehensive geological mapping and microfacies analysis, the lithological units recognized in the Hainholz quarry can be traced - with lateral variations in facies development and thickness - throughout the Osterwald Mountains. However, even at a distance of few km from the Osterwald Mountains, the Korallenoolith Formation differs in facies development and vertical facies patterns, so that a correlation of the sedimentary succession up to now appears almost impossible. When compared to the overall development of the Korallenoolith Formation in NW Germany, the reduced thickness of the Korallenoolith Formation exposed in the Osterwald Mountains is a notable feature. Furthermore, the erosional unconformity at the top of the basal oolite succession indicates a prominent hiatus in the Osterwald Mountains that is positioned at the base of the reefal deposits. Whether or not this unconformity can be correlated with the well developed lowstand unconformity at the top of the widely distributed florigemma-Bank Member ("Hauptdiskontinuitätsfläche") that terminates reefal development remains unsettled. The middle lithological subunit (Hainholz Member) is developed as a reef complex with abundant coral thrombolite patch reefs imbedded in and interfingering with reef rubble. Its exposed dimensions make it the largest reef complex known from the Late Jurassic sedimentary succession in the Lower Saxony Basin.</ABSTRACT>

- 14087 <SOURCE>Comptes Rendus Geosciences 336, 1: 59-66.</SOURCE>
- 14088 <ABSTRACT>The study of sedimentary facies in the quarry of Dompcevrin (Middle Oxfordian) located northwestward of St-Mihiel (Meuse department) provides evidences of high-energy depositional conditions. The occurrence of beaches associated with hurricane coral breccias containing megaclasts is characteristic of platform edge environments. The open sea was located northeastward, in the direction of Germany, as it is indicated by the direction of progradation of beaches. It is concluded that the Oxfordian carbonate platform of Lorraine was opened to the northeast toward the Germanic Sea during the Middle Oxfordian.</ABSTRACT>

- 14125 <TITLE>Coral-microbialite reefs in pure carbonate versus mixed carbonate-siliciclastic depositional environments: the example of the Pagny-sur-Meuse section (Upper Jurassic, Northeastern France).</TITLE>

- 14126 <SOURCE>Facies 50, 2: 229-255.</SOURCE>
- 14127 <ABSTRACT>Middle to Upper Oxfordian reefs of a shallow marine carbonate platform located in northeastern France show important facies changes in conjunction with terrigenous contents. The Pagny-sur-Meuse section shows coral-microbialite reefs that developed both in pure carbonate limestones and in mixed carbonate-siliciclastic deposits. Phototrophic coral associations dominated in pure carbonate environments, whereas a mixed phototrophic/heterotrophic coral fauna occurred in more siliciclastic settings. Microbialites occur in pure carbonate facies but are more abundant in mixed carbonate-siliciclastic settings. Reefs seem to have lived through periods favourable for intense coral growth that was contemporaneous with a first microbialitic layer and periods more favourable for large microbialitic development (second microbialitic layer). The first microbialitic crust probably developed within the reef body and thus appears to be controlled by autogenic factors. The second generation of microbialites tended to develop over the entire reef surface and was probably mainly controlled by allogenic factors. Variations in terrigenous input and nutrient content, rather related to climatic conditions than to water depth and accumulation rate, were major factors controlling development of reefs and their taxonomic composition.</ABSTRACT>

- 14139 <SOURCE>Geologische Beiträge Hannover 02: 51-64.</SOURCE>
- 14140 <ABSTRACT>An overview is given here on the palaeobiography of the Korallenoolith Formation (middle Oxfordian to early Kimmeridgian) in NW Germany (Lower Saxony Basin). Based on microfossils observations, abundant faunal and floral elements of the tropical tethyan realm are recognized in shallow-marine calcareous sediments of the Korallenoolith Formation. Foraminiferal fauna is both highly diverse and abundant and mostly of mediterranean character. Also, there is a small flora recorded, which includes heavily calcified red algae, aragonitic green algae, and cayeuxiid algae. They display restricted diversity when compared to those of shallow-marine tropical tethyan seas. Chaetetids and diceratids are locally abundant. Lithocodium aggregatum and Bacinella irregularis have been observed in Late Jurassic palaeolatitudes north of the Tethys for the first time. Corals are present in numerous genera and species. Their occurrence is restricted to a few horizons of the Korallenoolith formation where they build patch reefs, coral biostroms and coral meadows. The overall character of the coral-thrombolite-reefs (florigemma-Bank Member) is very similar to those of the Tethys. The presence of these marine tethyan taxa assigned the position of the Lower Saxony Basin during middle Oxfordian to early Kimmeridgian paleobiographically into the submediterranean province and reflects northward migration of tropical tethyan fauna and flora which reach in the Lower Saxony Basin their northern limit. These biota seem to be biogeographically transitional between communities present in England and the Tethys.</ABSTRACT>

14151 <TITLE>Entwicklung und Faziesverteilung eines Riffkomplexes im Korallenoolith (Oberjura) des Osterwaldes (Niedersachsen).</TITLE>
14152 <SOURCE>Geologische Beitrage Hannover 02: 31-50.</SOURCE>
14153 <ABSTRACT>The Hainholz quarry in the Osterwald hills of NW-Germany is the most impressive outcrop in the Lower Saxony Basin exposing Late Jurassic (Korallenoolith, Oxfordian) coral buildups. The Korallenoolith deposits in the quarry commence with a oolitic sequence about 20 m thick which is limited by a distinctive hardground at its top. This sequence is overlain by the so called "Obere Korallenbank"-Member about 13 m in thickness which is mainly build up by coral reef complexes. Throughout a lateral extend of about 400 m exposed in the quarry, the Obere Korallenbank Member shows numerous pillar-shaped reefal build ups which are flanked by a reefal debris limestone. The coral fauna of the in situ reefal bioconstructions comprises not less than 37 taxa most of which have been described from the Lower Saxony Basin for the first time. Probably, the pillar-shaped reefs formed a small positive relief of only a few dm against the debris deposits during deposition. The interreef debris limestones in the lower and middle part of the Obere Korallenbank Member show three intercalated biostromal coral layers. In the upper part of the member, the interreef facies is represented by a mikritic peloidal limestone rich in sponge remains and, unusual in such a depositional environment, ammonites (Dichotomosphinctes bifurcatoides, D. sp.). Additionally, at the top of the peloidal limestone a layer enriched in nerineids and other gastropods limits the reefal constructions of the Obere Korallenbank Member against the overlaying "humeralis-Oolith" sequence. On the basis of the facies development of this depositional sequence the reef formation in relation to sea-level changes is discussed.</ABSTRACT>

- 14192 <ABSTRACT>The coral patch-reef of Laisacker (Neuburg a.d. Donau, Southern Franconian Alb) exhibits three facies zones: the reef core consists of reef debris, there is almost no reef framework. The core facies, interfingering with the reef debris facies is built up by fine-grained reef detritus with intercalated coarse-grained layers of partly high porosity (up to 24%). They mainly consist of coral fragments (up to 83%) and reach 0.80 m in thickness. These coarse-grained layers have been formed by storms. The interreef facies corresponds to massive limestones. Destruction of the reef framework was favoured by bioerosion. The high still open porosity of the coarse-grained reef rubble was caused by high freshwater flow rates delimiting cementation and favouring dissolution.</ABSTRACT>

- 14204 <SOURCE>Facies 52, 3: 441-467.</SOURCE>
- 14205 <ABSTRACT>Small reefal bioconstructions that developed in lagoonal settings are widespread in a few horizons of the Late Jurassic (Oxfordian) succession of the Korallenoolith Formation, exposed southwest of Hannover, Northwest Germany. Especially the florigemma-Bank Member, "sandwiched" between oolite shoal deposits, exposes a high variety of build-ups, ranging from coral thrombolite patch reefs, to biostromes and to coral meadows. The reefs show a distribution with gradual facies variations along an outcrop belt that extends about 30 km from the Wesergebirge in the NW to the Osterwald Mts in the SE. The patch reefs from the Deister Mts locality at the "Speckhals" are developed as coral-chaetetid-solenoporid-microbialite reefs and represent a reef type that was hitherto unknown so far north of its Tethyan counterparts. They are mainly built up by coral thickets that are preserved in situ up to 1.5m in height and a few metres in diameter. They contain up to 20 coral species of different morphotypes but are chiefly composed of phaceloid Stylosmilia corallina and Goniocora socialis subordinately. The tightly branched Stylosmilia colonies are stabilized by their anastomosing growth. The coral branches are coated with microbial crusts and micro-encrusters reinforcing the coral framework. Encrusters and other biota within the thicket show a typical

community replacement sequence: *Lithocodium aggregatum*, *Koskinobullina socialis* and *Iberopora bodeuri* are pioneer organisms, whereas the occurrence of non-rigid sponges represents the terminal growth stage. The latter are preserved in situ and seem to be characteristic so far poorly known constituents of the Late Jurassic cryptobiont reef dweller community. The distance and overall arrangement of branches seems to be the crucial factor for the manifestation of a (cryptic) habitat promoting such community replacement sequences. Widely spaced branches often lack any encrusting and/or other reef dwelling organisms, whereas tightly branched corals, as is *St. corallina*, stimulate such biota. Hence, such reefs are well suited for research on coelobites and community sequences of encrusting and cavity dwelling organisms.

</TITLE>

14217 <SOURCE>Sedimentary Geology 197, 3-4: 235-266.</SOURCE>

14218 <ABSTRACT>In the present study, the difficulty which lies in the identification of sea-level fall discontinuities in deep depositional environments led the authors to use the transgressive surfaces (i.e. the most noticeable surfaces in the present case) to determine depositional cycles. Four (3rd order?) Lower and Middle Oxfordian cycles were identified (S1, S2, S3, and S4) in the Eastern Paris Basin. These four cycles can be organised into two lower frequency cycles (So I and So II) which comprise the S1, S2 and the S3, S4 cycles respectively. During the time intervals of the S1, S2, and S3 cycles, sedimentation occurred along a southward dipping carbonate-siliciclastic ramp, prograding from the northern Ardennes area. The S4 cycle shows the development of a reefal distally steepened ramp which subsequently evolved into a flat-topped platform as a result of the compensation infill of the available accommodation space by the carbonate production during a climatic warming, in this case reef growth. Isopach and facies maps suggest syndepositional activities of Hercynian faults coevals with the floodings of the So I and So II cycles. One of these events generated a diachronism of the maximum flooding (Plicatilis zone) during the So II cycle between the northwestern and southeastern parts of the studied area. The depositional patterns found in the Eastern Paris Basin and the Swiss Jura show great similarities for the Early-Middle Oxfordian. Both regions were probably connected and recorded the same tectonosedimentary evolution. In contrast a tectonic control certainly generated differences between the sequence-stratigraphic framework of the Eastern Paris Basin and the eustatic chart.</ABSTRACT>

14230 <SOURCE>Terra Nova 18, 3: 191-201.</SOURCE>
14231 <ABSTRACT>Oxfordian reefal episodes of Lorraine and Burgundy have a long time been considered as contemporaneous. Biostratigraphic data and sequential evolutions peculiar to each region indicate their structural autonomy during Oxfordian times. A north-south oriented well-logging transect shows that, during the Middle Oxfordian, a shallow reefal platform developed in Lorraine while thin deeper deposits occurred in Burgundy. In spite of their different ages, reefal episodes of Middle Oxfordian in Lorraine and Upper Oxfordian in Burgundy exhibit a broadly similar vertical evolution of coral communities. During the Late Oxfordian, the contemporaneous occurrence of a diversified assemblage in the Burgundy region, a colder coral assemblage characterized by eurytopic genera and the decrease in seawater isotopic temperatures in Lorraine can be explained by a shift in trophic conditions, a climatic change related to structural rearrangements in this strategic place and a modification of oceanic circulations between the arctic and the Tethyan regions.</ABSTRACT>

14256 <SOURCE>Bulletin de la Societe geologique de France 8, 5, 6: 1217-1225.</SOURCE>
14257 <ABSTRACT>The coral limestones from the Lower Callovian of Etrochey, near Chatillon-sur-Seine (Cote-d'Or) represent one of the last sequences of the Burgundy platform at the end of the Middle Jurassic. The geometrical arrangement of the reefs and associated facies shows a progressive development with competition between constructive and other organisms, and interference between biological and physical factors of the environment. Three sedimentary units can be recognized, corresponding to three successive steps in the coral complex formation. The size and the frequency of corals decrease up through the reef. The

development of the biological frameworks, their biodegradation by borers (bivalves and clionid sponges) and their colonization by encrusting organisms (sponges and oysters) are controlled by the amount and frequency of the oolitic and bioclastic sand supply which is a major limiting factor. The successive steps of biological constructions and biological destructions, controlled by organisms can be considered as a palaeoecological succession. However the action of the limiting factor, linked with a decrease in water depth results in a termination of the reef growth and biodegradation, and this occurs at an earlier stage in the younger units. Thus the three successive units appear as an upside down palaeontological succession, reflecting a stronger external control on reef development.</ABSTRACT>

14308 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 139, 3-4: 139-175.</SOURCE>
14309 <ABSTRACT>During the late middle Oxfordian, patch reefs grew on the northern margin of the Paris Basin. According to the facies analysis of the reef and inter-reef sediments, the environment was a warm, clear and agitated sea with highly episodic sedimentation. The bioherms were a short-lived phenomenon during the third phase of regional reefal development. Sequence stratigraphically, they are associated with a highstand system tract. Volumetrically and trophically dominant organisms were microbes now represented by massive clotted leiolite; 'stalactitic'; hemispheroids with purely thrombolitic texture are restricted to open caves. Corals were of structural, reef-building importance due to their rapid upward growth. The patch reefs are characterized by thickets of ramose corals which developed a very open framework. In the vicinity of these patch reefs, though in hydrodynamically higher-energy environments, grew thickets of more stoutly branched corals; however, they are rarely preserved in situ and are generally represented as abundant coral rubble. The reef taxa are characterized by the notable absence of several groups (e.g. oysters, serpulids, bryozoans, pectinids) occurring at other localities where reefs of similar age developed in similar environmental conditions. The reefs also have strikingly modern aspects to them, in particular the presence of cryptic elements within caves and a sponge-dominated borer association. Dwellers belong to various life-form types although encrusting taxa are exceedingly rare. This may be explained by the presence of soft microbial films on most surfaces. The palaeoecological analysis suggests that the major controls on faunal composition and high diversity were elevated nutrient levels, highly episodic sedimentation and probably seasonal environmental disturbances. Structural and functional aspects of the reef community (grazers trigger framebuilders, borers trigger binders, binders hamper borers) allow ecological comparisons to be made with contemporaneous, as well as Recent, reefs. The unique combination of ecological comparisons to be made with contemporaneous, as well as Recent, reefs. The unique combination of ecological factors resulted in a specialized, previously undescribed, community which differs from both Tethyan and northern localities in various aspects; these include cavities with cryptofauna, prominence of grazing gastropods and high faunal diversity in a microbially dominated build-up.</ABSTRACT>

14334 <SOURCE>Geol. Bl. NO-Bayern 43, 1-3: 33-56. [in German, with English summary]</SOURCE>
14335 <ABSTRACT>Case studies of two early Tithonian coral reefs in Southern Franconia exhibit the quantitative importance of bioclastic debris not only in the composition of reef talus adjacent to the reef core but also for the reef core itself. Extensive bioerosion in combination with episodic storms might have been responsible for the formation of these sand piles which were stabilized by micritic pellet crusts and early marine carbonate cements. Allochthonous and autochthonous parts of the reefs are characterized not only by different microfacies types but also by the distributional patterns of fossils (specifically foraminifera).</ABSTRACT>

14347 <SOURCE>Profil 6: 1-207. [in German, with English and Portuguese summary]</SOURCE>
14348 <ABSTRACT>During the Late Jurassic, the Lusitanian Basin of Portugal experienced an intensive rifting phase which caused pronounced bathymetric and, hence, facies differentiation. Particularly during the Kimmeridgian and Tithonian, siliciclastics were fed into the basin, resulting in a mixed carbonate-siliciclastic basin fill. Carbonate platforms and isolated coraliferous reefs of different dimensions and composition frequently developed within this setting. A shallow-water carbonate platform exhibiting distinct facies zonation is represented by the narrow Ota Platform (Kimmeridgian). The buildup exhibits an aggradational architecture and is rimmed by a high-energy, high-diversity coral reef. In contrast to most other Upper Jurassic high-energy reefs, the Ota coral reef contains abundant microbial and algal crusts. This was due to the achievement of equilibrium conditions

between production and export of debris, which can be explained by the existence of a tectonically caused, steep by-pass margin. Sedimentation in interior platform settings is mostly characterised by stacked, autocyclic, small-scale shallowing-up sequences. The narrow Ota buildup developed over a basement horst and was protected from surrounding siliciclastics by its elevated position and a strong longshore current. The Castanheira slope-type fan delta (Kimmeridgian) also formed at the strike-slip margin of a continental pull-apart subbasin. The fan sediments are dominated by coarse arcose conglomerates. Coral-microbial reefs grew on deactivated fan areas during two phases of relative sea-level rise. Collapse events in the course of sea level falls led to resedimentation of allochthonous limestones in more distal fan areas. [part of extensive summary] </ABSTRACT>

14360 <SOURCE>Profil 8: 1-237. [in German, with English abstract]</SOURCE>

14361 <ABSTRACT>Upper Jurassic deposits occur widespread along the northern Tethyan shelf and the marginal basins of the young North Atlantic Ocean. This work focusses on the sedimentological and palaeoecological comparison of two Portuguese sedimentary basins (Arruda Subbasin, eastern Algarve Basin) and the Celtiberian zone of eastern Spain. Based on this comparative analysis, regional and global factors controlling the depositional development are deduced. The Upper Jurassic sediments in all three Iberian basins are characterised by large-scale, mixed carbonate-siliciclastic, shallowing-upward successions. Typically the development started with Oxfordian, ammonite-bearing deeper water carbonates which were overlain by slope deposits consisting of marls, turbiditic sandstones and intraclastic limestones (Lower Kimmeridgian). Superimposed were reefal shallow water carbonates of Lower / Upper Kimmeridgian age. Besides rimmed shelves (Ota Limestone, Arruda Subbasin) and buildups on deactivated fan-lobes (Castanheira reef, Arruda Subbasin), the mixed carbonate-siliciclastic systems were more frequently arranged in ramp configurations. The Celtiberian zone, located on the stable northern Tethyan shelf represented a homoclinal ramp situation, whereas the Arruda Subbasin was characterised by an intense differentiation due to tectonic activity. Hence distally steepened ramp settings could only develop on the shallow dip slope of the tectonically inactive eastern margin of the half-graben basin. The eastern Algarve Basin exhibited both distally steepened and homoclinal ramp configurations, which was due to halokinetic differentiation and regional tectonic. This study concentrates on the coral-bearing shallow water deposits, which encompass a great variety of different reefal structures. According to their morphology and composition (amounts of metazoans, microbial crusts and reefal debris) 16 reef types with at least 15 faunal assemblages and associations could be distinguished. 14372 <TITLE>Etude du complexe récifal de Bellême (Normandie, France).</TITLE>
14373 <SOURCE>Proceedings of Second Intern. Symposium on Coral Reefs, Great Barrier Reef, Australia: pp??</SOURCE>
14374 <ABSTRACT>Le récif de Bellême signalé par L. Dangeard (1939-1940) et décrit par le même auteur (1950), est étudié à nouveau à la lumière des nouvelles méthodes de pétrologie sédimentaire et de paléocéologie. Ainsi, nous avons pu donner des détails plus précis sur sa description et établir des comparaisons plus objectives avec certaines formations actuelles. * La répartition stratigraphique des faunes a permis de donner un âge Séquanien supérieur - Kimméridgien inférieur à la formation. L'étude de la répartition écologique des fossiles récoltés, celle des différents faciès, microfaciès, nanofaciès et de leurs répartitions dans le complexe récifal, ainsi que les variations géochimiques mesurées au sein de la formation ont conduit à conclure que le terme de récif ne peut être appliqué à la formation du jurassique supérieur de Bellême et qu'il doit être remplacé par le terme de mud bank (l'élément madréporique de la lentille est monospécifique, l'espèce *Thamnasteria cf. dendroidea* est une espèce à branches ténues, les colonies ne sont pas jointives mais séparées les unes des autres par une fine micrite). Ce mud bank situé dans la zone subtidale pouvant passer en zone intertidale avec formation de calcarénite, d'oolithes et de beach rock, était probablement entouré de chenaux de marée divagants où la vitesse de l'eau était plus grande que celle des eaux des zones contiguës. Les conditions de vie étaient confinées (faible taille des individus, nombre restreint de genres et d'espèces). * Le remplacement du terme récif par celui de mud bank à cette place du Jurassique supérieur de Normandie a probablement une signification paléogéographique qui sera étudiée dans la suite de nos recherches sur les formations carbonatées de Normandie.</ABSTRACT>

- 14490 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 193, 3-4: 383-404.</SOURCE>
- 14491 <ABSTRACT>During the Early Kimmeridgian, the northern margin of the Aquitaine Basin (Western France) is characterised by a significant development of coral reefs. The reef formation of the Chay Peninsula comprises two main reefal units, in which the microbial structures can contribute up to 70% of framework. The microbial crusts, which played an important role in the stabilisation and growth of the reef body,

show the characteristic clotted aspect of thrombolitic microbialites. Corals are the main skeletal components of the build-ups. The bioconstructions of the Chay area are thus classified as coral-thrombolite reefs. Four main morpho-structural types of microbial crusts are distinguished: (1) pseudostalactitic microbialites on the roof of intra-reef palaeocaves; (2) mamillated microbialites, found either on the undersides or on the flanks of the bioherms; (3) reticular microbialites in marginal parts of the reefs and between adjacent bioconstructed units; and (4) interstitial microbialites in voids of bioclastic deposits. Thrombolitic crusts developed on various substrates such as corals, bivalves, or bioclasts. The thrombolites formed a dense, clotted and/or micropeloidal microbial framework, in which macro- and micro-encrusters also occur. Variations in accumulation rate strongly influenced the reef morphology, in particular its relief above the sediment surface. The coalescence of the coral-microbialite patches created numerous intra-reef cavities of metre-scale dimensions. The direction of microbial growth, which defined the macroscopic microbialite forms, strongly depended on the position within the reef framework but was also controlled by water energy, accumulation rate and light availability. 14542 <SOURCE>Zapadne Karpaty, ser. paleont. 13: 81-107. [in French, with English summary]</SOURCE>
14543 <ABSTRACT>The coral fauna from the Pribor area has already been known on the basic of F. Trauth's (1911) paper. The corals form part of the clastic rocks redeposited in the Frydek and Trinec Members (Senonian to Paleogene) of the Subsilesian unit of the Carpathian Flysch. Thus, the probably Upper Cenomanian to Lower Santonian age of the coral fauna, does not agree with the age of the host rock which is younger. In the present paper 18 coral species are described, of which one belongs to a new genus and 3 species are new. The coral assemblage is of a transitional character between the Cretaceous coral assemblages of the epi-Variscan platform and those of the Tethys (the Carpathians and the Alps). The coral fauna from the Pribor area represents a pioneer assemblage existing during a short stage of favourable conditions, probably on the western side of the Baska cordillera. During the Laramian or younger movements, the already silicified coral colonies were redeposited in rather deep parts of the Subsilesian basin.</ABSTRACT>

14554 <TITLE>Sedimentation of a Lower Cretaceous (Aptian) coral mound complex, Zaraya Mountains, northern Spain.</TITLE>
14555 <SOURCE>Geological Magazine 120, 4: 423-434.</SOURCE>
14556 <ABSTRACT>A Lower Cretaceous mixed carbonate-siliciclastic sequence is well exposed in Zaraya Mountains in Guipuzcoa Province, northern Spain. The sequence begins with interfingering deltaic platform facies and marine patch-reef carbonates. This unit is dominated by mudstones and

sandstone with minor interbeds of shallow-water carbonates (calcareous mudstones and sandstones and grain-stone-packstones). A thick mixed carbonate-terrigenous unit overlies the siliciclastics and is composed principally of limestones and marls. Periodic influx of terrigenous sediments over a dominantly carbonate sea-floor gave rise to repeated cycles typical of a mixed shallow-water platform. Demise of a southerly derived deltaic input allowed the development of a mainly carbonate third unit. Large (several metres across) bioherms resulted from high in situ organic productivity (mechanical breakage of bioclasts, algal-induced precipitation, trapping and baffling of lime mudstone). The mounds grew making up a coral carbonate mound complex. This progrades to the south, towards a small backreef basin, and slightly retreated in its forereef margin. A period of tectonic instability is thought to have been responsible for the drowning of the shallow-water complex, which was unable to keep pace with relative sea-level rise.

14595 <ABSTRACT>Coral material which has been systematically collected in the past 15 years - mostly in the Cenomanian of the Upper Cretaceous of Saxony (Cenomanian-Turonian) - indicates that the corals (Hexacorallia and Octocorallia) dominate in the limestone facies of the transgressive horizons. The revision of the rich collections has not yet been finished, however, in this paper the taxonomic state of knowledge is given, which is accompanied by a short introduction on the history and a description of the localities. Up to now, 63 species in 43 genera are known: 29 species from the Lower Cenomanian, 37 species from the Upper Cenomanian and three species from the Turonian.</ABSTRACT>

14620 <SOURCE>Coral Research Bulletin 02: 1-19.</SOURCE>
14621 <ABSTRACT>The monograph outlines the geology, facies and palaeoecology of the Cretaceous coral-bearing sediments of the Kassenberg quarry in Muelheim/Ruhr (Westfalian Cretaceous Basin, NW-Germany), access to which has become difficult. Several particularly reconstructed profiles give an overview over the bedding. On its base the possible sedimentation cycles from the Lower Cenomanian to Upper Turonian are discussed. The palaeontological research is documented by a list of the published papers on the locality. A reconstruction of the Cenomanian habitat, facies and sedimentation of the Kassenberg site is attempted with the aid of studies conducted on Mediterranean abrasions platforms. The occurrence of the corals is discussed and compared to other localities of Cenomanian / Turonian age.</ABSTRACT>

14634 <ABSTRACT>Part 2 of the monograph deals with the corals found at the Kassenberg site. The relatively small fauna of a pronounced Jurassic character comprises 41 species of hermatypic corals belonging to 30 genera of both Hexacorallia and Octocorallia. A comparison with type material from the Cretaceous in France, Saxony (Germany), Austria, Slovenia, Serbia, the Czech Republic and from the Jurassic in Poland and Romania augments the existing knowledge of some species and genera. The families Stylinidae and Haplaraeidae and the genera Acrosmilia, Adelocoenia, Epistreptophyllum and Mixastraea are dealt with in detail. In the concluding chapter, the coral fauna is compared - both geographically and stratigraphically - with other coral faunas of the Lower to Middle Cretaceous.</ABSTRACT>

14660 <ABSTRACT>[this is] the first part of the monograph [which] outlines the geology, facies and palaeoecology of the Cretaceous (Lowermost Cenomanian to Upper Turonian) coral-bearing sediments of the Kassenberg quarry in Mülheim / Ruhr (Westfalian Cretaceous Basin, NW-Germany), access to which has become difficult. Several particularly reconstructed profiles give an overview over the bedding. On its base the possible sedimentation cycles from the Lower Cenomanian to Upper Turonian are discussed. The palaeontological research on the locality is documented. A reconstruction of the Cenomanian habitat, facies and sedimentation of the Kassenberg site is attempted with the aid of studies conducted on Mediterranean abrasion platforms. The occurrence of the corals is discussed and compared to other localities of Cenomanian / Turonian age. In addition, two assemblages of calcareous nannofossils

- are introduced and their stratigraphical value discussed. </ABSTRACT>

- 14671 <TITLE>Reef development on a deepening platform: two Early Cretaceous corallgal patch reefs (Catí, Llacova Formation, eastern Spain) compared.</TITLE>
- 14672 <SOURCE>Cretaceous Research 26, 6: 864-881.</SOURCE>
- 14673 <ABSTRACT>Two corallgal patchreefs of the Hauterivian Llacova Formation (Maestrat Basin, E-Spain), subsequently exposed within one section, were investigated to reveal the taxonomical implications of changing environmental controls on reefal palaeocommunities. After taxonomical work on the coral fauna, microfacies analysis and palaeoecological interpretation, two communities could be distinguished that differ in coral taxonomical composition, microbialite formation pattern and in abundance and composition of encrusters and bioeroders. The coral fauna comprises 14 species (e.g. Actinastrea pattoni, Cladophyllia aff. catalaunica, Dimorphocoenia cf. crassisepta, Dimorphocoenia rudis, Eocomoseris raueni, Eocomoseris sp., Holocoenia jaccardi, Latusastrea irregularis, Mesomorpha sp., Microsolena kugleri, Polyphylloseris cf. mammillata, Polyphylloseris mammillata, Polyphylloseris sp., Styliina parvistella) and differs on the species level between the reefs. Only one coral species (S. parvistella) occurs in both the lower (abundant) and the upper reef (rare, occurs near the reef base). The lower reef was dominated by phototrophic fauna and coral species that show small corallites with nonperforate septa (a stylinid, thamnasteriid, heterocoeniid, actinastreid association) predominate together with Abacinella-Lithocodium dominated encruster association. The upper reef had a balanced phototrophic-heterotrophic fauna that gradually passed into a heterotrophic-dominated fauna during its latest growth stage where microsolenid corals predominated. The encruster spectrum is dominated by an association of sponges, polychaets and bryozoans. Moderate deepening during a transgressive systems tract (TST) depositional sequence and elevated nutrient supply are interpreted to represent the driving environmental parameters that caused this change in reefal palaeocommunity composition. In addition, we determined nine coral species that were only known from younger strata (Barremian, Aptian, Albian, Cenomanian) which emphasizes the importance of the Hauterivian as a time of evolutionary transition from Late Jurassic to Cretaceous coral faunas.</ABSTRACT>

14698 <SOURCE>Berliner geowissenschaftliche Abhandlungen A134: 107-117.</SOURCE>
14699 <ABSTRACT>From the lower Campanian of the quarry "Alemania Hover " a lot of sponge spicules mainly microscleres are described. This discovery is the first record of microscleres from this outcrop. These microscleres are related to the demosponge taxa Poecilosclerida (chelae, diancistra, toxa), Tetractinellida (sterraster, oxyaster) and the hexactinellid taxon Amphidiscophorida (hemidisc). Sterraster microscleres are firstly reported from the lower Cambrian of South Australia. These spicules, and the Cretaceous ones, are compared with the taxon Rhaxella perforata Hinde. Besides these microscleres some monaxonic demosponge megascleres (strongyles, oxea, subtylostyles, cricoamphioxea) were also collected.</ABSTRACT>

14723 <TITLE>The Hexactinellid Sponge Genus Becksia Schlueter 1868 from the Campanian of the NW Muensterland (Upper Cretaceous, NW Germany).</TITLE>
14724 <SOURCE>In: Reitner J. & Keupp H. (eds): Fossil and Recent Sponges: 21-35.; Springer, Berlin - Heidelberg.</SOURCE>
14725 <ABSTRACT>In the district of Coesfeld near the villages of Holtwick, Osterwick, Darup and Lette, northwest area of the Muenster Cretaceous Basin, extraordinary associations of hexactinellid and lithistid

sponges are exposed. These occur in Late Senonian strata [late Lower Campanian (Campanian 2-3)]. The regional so-called Osterwicker Schichten include alteration layers of glauconitic-sandy, argillaceous and calcareous marls, and marly limestones. A first systematic review indicates a dominance of hexactinellid sponges as opposed to lithistid ones. The Lithistida are represented by species of the genera Callopegma, Seliscothon, Verruculina, Jerea, and Siphonia. The Hexactinellida comprise species of the genera Aphrocallistes, Becksia, Camerospongia, Coeloptychium, Coscinopora, Lepidospongia, Leptophragma, Plocoscyphia, Sporadoscinia, Tremabolites and Ventriculites (Gasse et al. 1988). Well known from this region is the occurrence of specimens of the genus Becksia. Also from this area the type species Becksia soekelandi was erected by Schluter (1868). Recently collected and well-prepared individuals of this species have stimulated the following remarks [on Becksia].

 14749 <TITLE>First record of the hydroid Protulophila gestroi Rovereto, 1901, a serpulid symbiont, from the Middle Cenomanian primus Event, northern Germany.</TITLE>
 14750 <SOURCE>Neues Jahrbuch für Geologie und Paläontologie, Monatshefte 2005, 4: 219-232.</SOURCE>
 14751 <ABSTRACT>The colonial hydroid Protulophila gestroi Rovereto, 1901, a common serpulid symbiont, is recorded for the first time from the lower Middle Cenomanian Praeactinocamax primus Event of northern Germany. It is represented by a reticulate system of thin stolons, small subcircular openings or chimney-like bosses, and elongate polyp chambers preserved by in vivo bioimmuration in the outer layers of the calcareous tubes of serpulid worms. From the rich serpulid fauna of the primus Event, only representatives of the genus Rotulispira Chiplonkar & Tapaswi are infested whereas other genera (e.g., Nogrobs (Tetraditrupa) Regenhardt and Pentaditrupa Regenhardt) appear to be not affected. This observation may indicate that P. gestroi was selective in the choice of its hosts, a phenomenon known also from recent colonial hydroids living as polychaete symbionts. A commensalic relationship is inferred for P. gestroi from the primus Event as the percentage of infestation (ca.40%) indicates that infested and non-infested serpulids were roughly equally successful in the same environment.</ABSTRACT>

14762 <TITLE>Hydrozoan build-ups of Millepora irregularis sp nov. and fungiid coral Meadows of Cunolites Alloiteau (Anthozoa).- Palaeoecological and Palaeoceanographical implications for the Upper Cretaceous of North Cantabrica (Northern Spain).</TITLE>
14763 <SOURCE>Facies 39, 1: 125-138.</SOURCE>
14764 <ABSTRACT>The Cantabrian Basin of northern Spain yields an Upper Santonian / Lower Campanian carbonate sequence, where both milleporid hydrozoans and fungiid corals established uncommon and hitherto unknown bioconstructions. The section where these bioconstructions are exposed can be divided in four lithological units. The hydrocoralline bioconstructions are developed as biostromes in unit one and as bioherms in unit three. Biostromes and bioherms are separated by unit two, a carbonate facies rich in "lithistid" and hexactinellid sponges. The hydrozoan colonies were preserved due to early diagenetic silicification of their formerly aragonitic skeleton. The examined fauna strongly resembles the Recent milleporid taxon Millepora alcicornis. Significant differences between fossil and Recent skeletal structures can be recognized only in the distribution of zoecial tubes within the coenosteum. The hydrozoan facies is topped by unit four, a quartz-rich limestone, with at least a dozen bed surfaces, each covered by dense meadows of a more or less monospecific fungiid coral fauna, assigned to the genus Cunolites Alloiteau. The milleporids developed in, at least intermittently agitated, shallow water environment with normal, open marine salinities. The sediment yields a microfacies rich in benthic foraminifera and bioclasts and poor in terrestrial components. The Cunolites fauna, instead, probably spread in a quiet, more restricted environment of a deeper lagoonal facies, poor in marine biogenes, except for some rare associated gryphaeid oysters and irregular echinoids. This facies is conspicuously influenced by terrigenous input, as is substantiated by abundant quartz minerals, wood fragments and small coal flakes. The conspicuous environmental change from the hydrozoan into the fungiid coral facies matches an approach of the coastline, obviously related to an Upper Santonian / Lower Campanian "tecto-event", which has been proved on a superregional scale. Both the milleporid hydrozoans and the fungiid corals point to a temporary influx of subtropical Tethyan ocean waters in the Boreal Realm of the Biskaya Ocean during this time.</ABSTRACT>

14827 <TITLE>An almost complete specimen of the Late Cretaceous (Campanian) octocoral *Isis ramosa* Voigt (Gorgonacea) from the Lower Saxony Basin, northwest Germany.</TITLE>
14828 <SOURCE>Cretaceous Research 24, 1: 35-40.</SOURCE>
14829 <ABSTRACT>An almost completely preserved specimen of the octocoral *Isis ramosa* (Mitteil. Geol. Staatsinst.Hamburg 27 (1958) 5) (Gorgonacea) is described. The specimen was found in Campanian strata in the Lower Saxony Basin near Hannover (NW Germany), presumably in the *Pachydiscus stobaeil* Galeola *basiplana* Zone of the regional northwest German zonation. It consists of a small, rigid, fan-shaped corallum that was formerly known only from a few poorly preserved fragments. This feature separates *Isis ramosa* significantly from related extant Isididae that expose a corallum subdivided into calcified internodes and horny nodes. *Isidid* species from deeper shelf settings with rigid branches and a presumed articulation only between root system and fan are interpreted as ancestral to extant gorgonaceans.</ABSTRACT>

14868 <ABSTRACT>A lectotype has been assigned for Placosmilia? robusta Umbgrove, 1925. This taxon, although fitting into the original diagnosis of Placosmilia, is not defined by the emended diagnosis of Alloiteau and later authors. Specimens from the Upper Maastrichtian of The Netherlands, that were formerly wrongly attributed to Galaxea fasciculata (Lamarck, 1816), a homonym of the extant species Galaxea fascicularis (Linnaeus, 1758), belong to Placocoenia macrophthalma (Goldfuss, 1826). The specimen depicted as P. macrophthalma by Umbgrove does not belong to this taxon and is placed in open nomenclature.</ABSTRACT>

14880 <SOURCE>Revista Espanola de Paleontología 16, 1: 131-144.</SOURCE>
14881 <ABSTRACT>Montlivaltia multiformis Toula (Scleractinia, Faviina, Montlivaltiidae), formerly reported from the Carpatho-Balkan domain is described from Lower Aptian beds of the Prebetic Domain (SE Spain). Taxonomic attributes include the organisation of radial elements, septal trabeculae, carinae and endothecal elements while the external morphology of the coralla is fairly variable. The sedimentological context suggests a circalittoral environment also supported by palaeoecological features of the surrounding fauna. Owing to its stratigraphic position in the Carpatho-Balkan region and in Spain, Montlivaltia multiformis appears as a potential marker for both shallow carbonate or outer shelf settings of the Lower Aptian Tethys European margin.</ABSTRACT>

14893 <SOURCE>Geologisches Jahrbuch A157: 69-97.</SOURCE>
14894 <ABSTRACT>The chalk quarries of Lägerdorf, Krons Moor (southeast of Itzehoe, Holstein) and Hemmoor (northwest of Stade, Lower Saxony) expose an early complete section from the upper Cretaceous (Middle

Coniacian to the Upper Maastrichtian) which has a thickness of 520m. It is chalk facies. Most of the solitary corals in this section are of the genera *Parasmilia* and *Trochosmilia* (*Coelosmilia*). From 300 corals more than 50% belong to these genera. The genus *Parasmilia* can be found from the Coniacian to the Maastrichtian, *Trochosmilia* can only be found in the Maastrichtian. Material for comparison from other quarries in North-Germany were not studied.</ABSTRACT>

14905 <TITLE>First Mesozoic record of the scleractinian *Madrepora* from the Maastrichtian siliceous limestones of Poland.</TITLE>

14906 <SOURCE>Facies 53, 1: 67-78.</SOURCE>

14907 <ABSTRACT>The objective of the present article is to document the first stratigraphic occurrence of the colonial oculinid *Madrepora*, known from the modern seas as azooxanthellate taxon that contributes to formation of deepwater coral reefs. The Upper Cretaceous specimens of *Madrepora* sp. reported herein from Poland were recovered from Upper Maastrichtian (Nasiłów and Bochotnica localities) and Lower Maastrichtian (Bliżów locality) siliceous limestones. The corals are preserved as imprints of the branch fragments and molds of the calices. Despite their moldic preservation, the coral remains exhibit key generic features of the genus *Madrepora*: (1) sympodial colony growth form with calices arranged in opposite and alternating rows in one plane of the branch, and (2) imprints of the granular coenosteum texture, occasionally showing peculiar reticulate patterns. Some features of the Cretaceous *Madrepora* sp., such as the reticulate coenosteum texture, the range of the corallite diameter (2.8-4 mm), and the arrangement of the septa in three regular cycles resemble the skeletal features of the modern, typically constructional, species *M. oculata* (type species). The lack of any evidence of coral buildups and related debris in the whole Upper Cretaceous/Paleogene sequences from Poland and the sparse occurrence of colony fragments, suggests that the Cretaceous *Madrepora* sp. formed small, isolated colonies.</ABSTRACT>

14919 <SOURCE>Abhandlungen und Berichte für Naturkunde und Vorgeschichte 21: 63-71.</SOURCE>

14920 <ABSTRACT>Five Lower Cretaceous localities in Northern Spain (near Castellví de la Marca, Masarbones and Montsec de Rubies) with rich coral faunas known from the historical literature were sampled and dated as Upper Aptian on the basis of foraminifers, rudists and calcareous algae. The dating was confirmed by the coral associations, despite their low stratigraphical value.</ABSTRACT>

14944 <TITLE>Colonial corals from the Early Aptian siliciclastic Montlivalentia Marls of Jumilla (Murcia, Spain).</TITLE>
14945 <SOURCE>Revista Espanola de Paleontologia 23, 1: 1-6.</SOURCE>
14946 <ABSTRACT>Three species of colonial scleractinian corals are reported from Early Aptian sandy marls of the so-called Montlivalentia marls from a section exposed on the SE flank of the Sierra de Sopalmo, south of Jumilla in Murcia, Spain. While solitary corals of the genus Montlivalentia are extremely common in the marls, colonial corals are rare. The three colonial coral species presented here (Cryptocoenia sp. n. aff. C. pygmaea, Holocystis elegans, and Columnocoenia aragonensis) are all common Early Cretaceous species. They range in age from the late Barremian to early Albian with the exception of Columnocoenia aragonensis, which ranges from the Valanginian to Cenomanian. Their geographical distribution is large and all species were found in the central Tethys as well as in the Caribbean province. All species were previously found in siliciclastic environments and while Holocystis elegans occurs primarily in such facies, the other two species occur in pure carbonates as well.</ABSTRACT>

14957 <TITLE>Low-light and nutrient-rich coral assemblages in an Upper Aptian carbonate platform of the southern Maestrat Basin (Iberian Chain, eastern Spain).</TITLE>
14958 <SOURCE>Cretaceous Research 29, 3: 509-534.</SOURCE>
14959 <ABSTRACT>A Lower Cretaceous (Aptian) succession of carbonate rocks in the southern Maestrat Basin (Iberian Chain, Spain) was analysed in terms of sedimentological and palaeontological criteria. The shallow

marine sequence was deposited upon a homoclinal carbonate ramp. Five main facies types were distinguished: (A) peloidal and bioclastic grainstones and rudstones of the inner ramp shoals; (B) orbitolinid wackestones-packstones of the distal outer ramp; (C) peloid and *Ostrea* wackestones-packstones of the middle outer ramp; (D) coral-algal sheetstones of the proximal outer ramp; and (E) coral-algal platestones-domestones of the middle ramp. Coral-bearing facies types (D) and (E) showed similar major environmental factors: low energy hydrodynamism, low light intensity and apparently nutrient-rich water. Slight differences in these conditions are reflected in the different growth forms and coral assemblages. Coral-algal sheetstones are characterized by sheet-like and lamellar forms with a low coral diversity not clearly dominated by any taxon. Coral-algal platestones-domestones develop platy, tabular and irregular massive forms with a slightly higher coral diversity characterized by a *Microsolenina*-*Faviina* association. The coral fauna is revised taxonomically and yielded a total of 22 species in 18 genera (21 *Scleractinia* species, one *Octocorallia* species). Genera of the suborders *Microsolenina* and *Faviina* predominate, those of the suborders *Stylinina*, *Fungiina*, *Rhipidogyrina* and the order *Coenothecalia* are subordinate.

 14970 <TITLE>Fauna and palaeoecology of the Middle Cenomanian *Praeactinocamax primus* Event at the type locality, Wunstorf quarry, northern Germany.</TITLE>
 14971 <SOURCE>*Cretaceous Research* 28, 3: 428-460.</SOURCE>
 14972 <ABSTRACT>A systematic account of the fauna from the early Middle Cenomanian *Praeactinocamax primus* Event, a 50-60cm thick marl bed, at the type locality, Wunstorf quarry, to the west of Hannover (northern Germany), is given. Numerous invertebrate taxa (over 50 in total) have been collected, including two species of belemnites, ten ammonites, at least 12 bivalves, a single scaphopod, five gastropods, at least eight brachiopods, two solitary corals, a single hydrozoan, four echinoids, and ten polychaetes. The benthic community of the *primus* Event clearly represents a soft-bottom fauna, with hard-bottom elements limited to secondary hard substrates. Most of the macrobenthic elements constitute suspension feeders; shallow-infaunal deposit feeders, grazers and microcarnivores occur as well, while deeper infaunal elements are largely missing. [first fragment of extensive summary]</ABSTRACT>

 14983 <TITLE>Die Korallen der sächsischen Oberkreide, Teil 1, *Hexacorallia* aus dem Cenoman.</TITLE>
 14984 <SOURCE>*Abhandlungen des Staatlichen Museums für Mineralogie und Geologie zu Dresden* 36: 88-164.</SOURCE>
 14985 <ABSTRACT>In den transgressiven Ablagerungen der sächsischen

Oberkreide im Suedosten der DDR nehmen Korallen in der Anzahl der Arten wie der auffindbaren Exemplare stellenweise einen hohen Rang ein. Die zumeist kolonialen, seltener solitaeren Formen sind relativ schlecht erhalten und erschwerten eine Untersuchung. Auf der Basis der Arbeit von Bolsche (1871) wird unter Einbeziehung der Originale mit vorliegender Publikation ueber die Scleractinia des Cenomans eine vollstaendige Neubearbeitung eingeleitet. Von den hier beschriebenen 31 Arten in 26 Gattungen, vor allem der Unterordnung Fungiina Duncan 1883, weniger der Unterordnungen Archaeocoeniina Alloiteau 1952, Astraeonina Alloiteau 1952 und Heterocoeniina M. Beauvais 1977, werden acht Arten offen, weitere drei vergleichsweise bestimmt. Die in Loeser (1987) vorgestellten beiden neuen Arten werden anhand den ihnen zugeordneten Arten naehr charakterisiert. Eine neue Art der Gattung Mesomorpha Pratz 1883 wird beschrieben.</ABSTRACT>

 14996 <TITLE>Dos nuevos generos de corales cretacicos.</TITLE>
 14997 <SOURCE>Batalleria 1: 39-45.</SOURCE>
 14998 <ABSTRACT>Two new genera of Cretaceous Scleractinia are described. They belong to superfamily Montlivaltioidae but the familial assignment is open. The diagnosis of the first one, named Pseudocunnulites is as follows: Solitary circular or discoidal. Lower face epithecate with many growth concentric rings. Upper faci with numerous radial septa strongly perforate. Columella fasciculate. Endotheca very thick. without synaptacula. The type species is Pseudocunnulites rosendoi n.sp., coming from Santonian of La Llobera (Villanova de Meia), Prepyrenees of Catalonia, NE of Spain. The diagnosis of the second genus, Angelismilia, is: Solitary, trochoid and with parathecal wall, covered by a smooth epitheca, followed by a second inner wall. Perforate septa. Abundant endotheca. Columella spongy and pseudolamellar. This new genus encloses the following species, described by De Angelis (1905): portisi (type species), neviani and sandalina. They were collected in Cenomanian of Castelvi de la Marca (Catalonia, NE of Spain).</ABSTRACT>

15076 <ABSTRACT>The origin Cretaceous genus Glenarea Pocta 1887 was rather unknown but often reported also from the Upper Jurassic. Now it is finally revised. In view at the main characters (a septothecal wall in a fashion zig-zag, a lamellar columella, a well developed and partial vesiculous endotheca, microstructure) Glenarea is placed in the family Meandrinidae. The genus Melikerona Alloiteau 1958 is considered to be a younger synonym of Glenarea. In addition a new species, Glenarea poctai, is described.</ABSTRACT>

15115 <ABSTRACT>Two coral faunas are described from the lower Cretaceous of northern Spain. Both are assigned to the Urgonian facies of Aptian-Albian age. Fifteen different species are reported from each fauna. They belong to the genera Heliocoenia, Cyathophora, Pseudocoenia, Pentacoenia, Latusastraea, Eugyra, Budaia, Lochmaeosmia, Columnocoenia (the worldwide distributed C. ksiazkiewiczi), Complexastraea, Epistreptophyllum (!), Placophyllia, Cladophyllia, Axosmia, Trochoidomeandra, Diploastraea, Dimorphastraea, Fungiastraea, Astraeofungia, Comoseris (!), Meandraraea, Meandrophyllia, Calamophylliopsis and Acrosmilia. A strong relation to upper Jurassic and lower Cretaceous faunas of Europe and Asia is shown.</ABSTRACT>

15139 <TITLE>Cretaceous scleractinian corals from the Albian of Cabo de Ajo (Cantabria Province, N-Spain).</TITLE>
15140 <SOURCE>Paläontologische Zeitschrift 71, 1-2: 35-40.</SOURCE>
15141 <ABSTRACT>For the first time a detailed stratigraphic section of the Lower Cretaceous (Albian) of Cabo de Ajo peninsula (Cantabria Province) is logged. The Ajo facies represents a subtropical shallow-water carbonate platform environment. When the platform was subjected to relatively high-energy conditions, calcarenite skeletal shoals developed. In periods of higher sealevel, deeper-water marls were deposited in intraplatform basins. The outcrops yield abundant fossils of scleractinian corals. Three selected stratigraphic horizons containing corals were sampled. Fauna 1 and 2 grew on a shallow-water soft bottom substrate (marl) below wave-base level and contain very small plocoid and phaceloid growth forms. Fauna 3 is associated with a calcarenitic matrix and large forms suggesting a more agitated and wave-influenced environment. 16 species of corals belonging to 7 suborders are described taxonomically. These rather diverse coral associations are among the youngest from the Urganian facies of Europe, and compare well with other Urganian Tethyan faunas.</ABSTRACT>

15154 <ABSTRACT>The present paper contains the last part of the new taxonomic descriptions of the Upper Cenomanian, Lower Turonian and Lower Coniacian corals from the Bohemian Cretaceous Basin. Nineteen taxa of scleractinian suborder and one species from Coenothecalia were described. One new genus *Colonicyathus* gen. nov. for *Placoseris geinitzi* Bolsche 1871, and the new species *Micrabacia wellsii* sp. n. (sooner described from the Bohemian Cretaceous Basin as *Micrabacia coronula* Goldfuss 1827), *Onchotrochus hatifnatus* Stolarski & Eliasova sp. n., and *Protrochocyathus* (?) *pergratus* sp. n. were proposed. All these three new species were ahermatypic scleractinian corals of Lower Turonian and Lower Coniacian ages.</ABSTRACT>

15167 <ABSTRACT>One of the two species is provisionally identified as
Trochocyathus conulus. According to the literature it should be quite
common in the Cretaceous of Europe. The generic attribution of the
other species is still uncertain. It is remarkable by its symbiosis
with a sipunculan (analogy with certain Recent scleractinians). It is
the oldest recognized case of this type of symbiosis in the Cretaceous.

15191 <TITLE>An example of auto-mobility and host substrate relationship in
"Cycloseris" escosurae Mallada 1887, scleractinian coral from
Lower Aptian of Spain.</TITLE>
15192 <SOURCE>Bolletino della Societa Paleontologica Italiana, Spec. vol. 3:
191-220.</SOURCE>
15193 <ABSTRACT>"Cycloseris" escosurae is an Early Aptian solitary
coral from Spain created [described!] by Mallada (1887). The taxonomic
revision indicates that the species of Mallada shows intermediate
characters between the genus Cycloseris Lamarck and Cyclophyllopsis
Alloiteau 1959, and, may be, it is pertaining to a new genus. This
small, discoidal coral is commonly settled on Palorbitolina tests and,
occasionally, on bivalve fragments, conchostracan shells, and others.
Few specimens do not display apparent attachment. The hypothesis of
Alloiteau (1952) concerning an association of Eocene solitary corals to
macroforaminifera as a case of commensal relationship is here
discussed. Architectural criteria for self induced mobility, such as
trabeculae directed also basally and the lack of epitheca, as
demonstrated within Recent Cycloseris cyclolites (Lamarck) suggest that
the species from Spain had been auto-mobile (Gill & Coates 1977).
The relationship between the coral and its host substrate is analyzed.

15230 <TITLE>Palaeoecologie von nordspanischen Korallen des Urgon (Playa de Laga, Prov. Guernica, N-Spanien).</TITLE>
15231 <SOURCE>Berliner geowissenschaftliche Abhandlungen E13: 441-451.</SOURCE>
15232 <ABSTRACT>The Playa de Laga, Guernica Province, Northern Spain (Vasco-Cantabrian) yielded corals from two limestones (KK I, KK II)

within a carbonatic/clastic shallow water sequence. The outcropping lithological units are attributed to the Urgonian complex. Among the colonial corals there are no encrusting or sheet-like forms; among the solitary taxa discoidal or flat growth-types are lacking. Plocoid and phaceloid morphotypes dominate, to a lesser extent there are also thamnasterioid and meandroid forms. Special growth-patterns (e.g. rolling stone-type; coverage by numerous tiny polyps; subhemispherical forms) indicate adaptation to shallow water and soft bottom substrate. Microfacies studies of the lower coral limestone point to an assignment to categories I2 to III of the Energy-Index after Plumly et al. (1962). The upper coral limestone falls in category III. The composition of the coral faunas, their growth-patterns, the conspicuous small size of individuals, as well as the microfacies, suggest deposition of both limestones in a lagoonal environment.

15243 <TITLE>El genero Eugyra en el Cretacico del nordeste espanol.</TITLE>

15244 <SOURCE>Batalleria 4: 31-36.</SOURCE>

15245 <ABSTRACT>Five species of the genus Eugyra are described from the Aptian of northeast Spain, three of which are new. The new species are: E. vivesi, E. cahadai and E. casanovai. This study deals also with E. aransensis Alloiteau and E. crassisepta Reig. D'Angelis (1905) cited from an outcrop in Garraf (Barcelona Prov.) the following taxa: E. coteauai and E. pusilla pauciseptata, the last one being a new subspecies. After careful study of the specimens kept in the Geological Museum of the Seminary of Barcelona, it is concluded that E. pusilla pauciseptata does not belong to genus Eugyra. The specimens labelled as E. pusilla pauciseptata are considered by Reig (1991) as several species of genus Hydnothophora. It is possible that E. coteauai may be present in Garraf. The description [distinction] between Eugyra and Hydnothophora is underlined. A principal distinctive feature is the form of the axial part of septa: tapering in Eugyra, and clubbing in Hydnothophora.

 15284 <ABSTRACT>The new scleractinian coral genus Hexasmiliopsis is described on the basis of material from the Early Aptian (Early Cretaceous) of Murcia (Spain). The new genus of the Heterocoeniidae family is characterised by its solitary growth form, a very strong main septum and the presence of apophysal septa. It is closely related to the genera Hexasmilia (phaceloid growth form), Rodinosmilia and Tiarasmilia (both without main septum). The genus is monospecific and represents only the type species, Hexasmiliopsis saldanai. [original abstract]

15296 <SOURCE>Neues Jahrbuch für Geologie und Palaeontologie, Abhandlungen 250, 1: 45-52.</SOURCE>
15297 <ABSTRACT>The morphological characteristics of the genus Hexasmilia de Fromentel, 1870 are analysed for the first time, using material from the type locality of the type species. The position of the genus within the Heterocoeniidae family (Heterocoeniina suborder) is confirmed. The genus differs from Heterocoenia by its phaceloid growth mode and the presence of apophysal septa. Up to now, Hexasmilia was believed a monospecific genus, but in addition to the type species, the genus includes the species Hexasmilia pachythecalia (Kuzmicheva, 1980), previously attributed to Hexapetalum. Hexasmilia elmari n.sp. from the Aptian of Spain is newly described and further material is presented in open nomenclature. The genus reaches from the Late Barremian to the Santonian. 15309 <SOURCE>Neues Jahrbuch für Geologie und Palaontologie, Abhandlungen 255, 3: 315-326.</SOURCE>
15310 <ABSTRACT>From the Early to Middle Albian of south-eastern Spain (Prebetic) a small coral fauna is reported. Five species are described. Four species belonging to the Leptophyllidae, Montlivaltiidae, and Cyathophoridae families are quite common in outcrops of an Aptian to Early Cenomanian age, mainly in the central Tethys and western Hemisphere. One species belongs to the Hemiporitidae family and represents only the second colonial coral genus known from the Meandrinina suborder in the Early Cretaceous, the first being Phyllocoenia. A short account is therefore given of the suborder Meandrinina, its history, taxonomic composition and diversity through the time. Due to the low quality of the material and the availability of only one sample, the material is preliminarily assigned to the genus Lamnastrea Reig Oriol 1997, which is herein revised on the basis of thin sections obtained from the type of the type species. 15321 <TITLE>Biotic interactions and synecology in a Late Cretaceous coral-rudist biostrome of southeastern Spain.</TITLE>
15322 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 193, 1: 125-138.</SOURCE>
15323 <ABSTRACT>A coral-rudist biostrome exposed in Campanian limestones near the village of Tabernas de Valldigna in southeast Spain was analysed

with respect to its palaeontology, sedimentology and palaeoecology. Special attention was given to possible evidence for synecological interactions between corals and rudists. Changes in the rudist shell accretion process are evident in some polished slabs and thin sections and resulted from in vivo contact with coral colonies. These unusual balcony-like shell protuberances exist where the rudist's commissure was in contact with corals. They likely represent defence-reactions of rudists against the coral cnidia. Nevertheless, the fossil record of these biotic interactions is rare. This may be due to different growth-rates of rudists and corals, differing shape and size of interacting areas, or different life-spans. In consequence, the discrete window of intergroup biotic interaction was small. Sedimentation and resuspension rates were high in the biostrome and corals only established pioneer associations under these unfavourable conditions. A higher diversity of corals is reached, however, when rudists are present. This increase in diversity resulted from the availability of additional ecological niches such as rudist-shell hard substrates and elevation above mobile sediment surface. Rudists on the other hand, received support from stabilisation of their shells through coral encrustation and framework building. In consequence, both groups benefited from their co-existence.

 15334 <TITLE>Nuevos datos sobre la fauna albiense de Traiguera (Castellon).</TITLE>
 15335 <SOURCE>Cuadernos geol. Iberia 17: 371-392. [in Spanish, with English summary]</SOURCE>
 15336 <ABSTRACT>The Albian outcrop of Traiguera (Prov. Castellon, NE Spain), was studied by Canerot & Collignon (1981). They described Ammonites, Bivalves and Gastropods. Here new paleontological data about Scleractinia and other [!?] Gastropoda are reported. This fauna derives from Middle Albian beds. Two genera of Scleractinia and seven species of Gastropods are described. The genus Oonia reaches Albian age. The synonymy of Helicacanthus octavius is pointed out. This species has a large distribution in the Tethyan Albian.</ABSTRACT>

15360 <TITLE>Eine caryophylliide Koralle aus dem Campan von Höver (" Hannoversche Oberkreide").</TITLE>
15361 <SOURCE>Arbeitskreis Paläontologie Hannover 26: 101-104.</SOURCE>
15362 <ABSTRACT>Über Korallen der campanzeitlichen Mergelkalk- und Kalkmergelfazies der Lehrter Westmulde (Misburg, Höver) gibt es bisher nur wenige Angaben. Korallen sind dort ausschließlich durch solitäre Formen vertreten. Am weitaus häufigsten findet sich Parasmilia, vor allem P. centralis Mantell (Frerichs 1992). Auch die Gattung Trochosmilia (Coelosmilia) ist vertreten (Niebuhr 1995: 49, Taf. 12/10). Beide Gattungen treten nach Niebuhr (1995:49) insbesondere im Untercampan und in der "Gebankten Kalkmergelfazies" der tieferen minor/polyplocum-Zone häufiger auf. Selten, und anscheinend in allen aufgeschlossenen Zonen vorkommend, ist die "Knopfkorallen "-Gattung Micrabacia (siehe Kruger 1983; Helm 1998). Micrabacia-Exemplare werden allerdings aufgrund ihrer geringen Gröβ e meistens übersehen. Darüber hinaus nennen Ernst et al. (1997) Einzelfunde von Desmophyllum sp.; und zwar ausschließlich aus der "vulgaris"/stolleyi-Zone (frühes Obercampan) der Grube Teutonia Nord. Onchotrochus minima (Bolsche) konnte der Verfasser erst kürzlich in zahlreichen Exemplaren in der Grube Alemannia bergen (Helm 1998). Letztgenannte Funde stammen aus der lingua/quadrata-Zone, Aus demselben Niveau liegt ebenso ein nahezu vollständiges Exemplar einer weiteren Korallenart vor. Der Einzelfund wird nachfolgend beschrieben. [original introduction]</ABSTRACT>

15375 <ABSTRACT>The study contains supplements to the diagnosis of the genus Leptophyllia Reuss 1854. Reuss (1854) has described representants of two genera under a single specific name, Leptophyllia clavata. One of them, with ornamentation on septa and ribs composed of grains (cf. Reuss 1854, PI. VI -figs. 3 and 6), was reassigned to the genus Acrosmilia d'Orbigny 1849, by M. Beauvais (1982). The second genus, whose species show penular ornamentation of radial septa (cf. Reuss 1854, PI. VI - figs. 4 and 5), remained anonymous till today. It is probable that the genus Leptophyllia and Acrosmilia which lasted for decades in the literature. Leptophyllia remains a valid genus. The species Leptophyllia cenomana Milne-Edwards & Haime 1849, and Leptophyllariaea svobodai sp. n. are systematically described. [slightly modified original abstract]</ABSTRACT>

15401 <ABSTRACT>Nine solitary corals from the Late Cenomanian sediments of the Bohemian Cretaceous Basin are described and discussed in this paper. These corals are poorly known representatives of the genera Leptophyllia, Leptophyllaræa, and Neothecoseris, and constitute the new taxon Leptophyllia separata sp. n. (suborder Microsolenina, family Synastræidae). The species Dimorphastræa parallela (Reuss) has been transferred to the genus Synastræa. Microphyllia gemina sp. n., a new species of family Latomeandridae, is described. Some comments on the species Synhelia gibbosa (Siderastræidae) of the Early Turonian age are added.</ABSTRACT>

15451 <TITLE>Karbonatbanke mit Lithocodium aggregatum Elliot / Bacinella irregularis Radoicic. Palaeobathymetrie, Palaeoökologie und stratigraphisches Äquivalent zu thrombolithischen Mud Mounds.</TITLE>
15452 <SOURCE>Berliner geowissenschaftliche Abhandlungen E03: 273-293.</SOURCE>
15453 <ABSTRACT>A section including Lithocodium / Bacinella boundstones with a thickness of up to 8m is reported from the Lower / Middle Albian of northern Spain. According to microfacies and sedimentological analyses the bathymetric position of the Lithocodium / Bacinella banks ranges from deeper subtidal to shallowest subtidal / intertidal conditions. The maximum depth is related to the photic zone, which itself is controlled by the amount of muddy suspension. The upper bathymetric limit is mechanically defined and corresponds to increased depositional energy (i.e. waves and tidal currents). Together with other algae and microbes Lithocodium / Bacinella is a major constituent of thrombolitic mud mounds (Gandara mound). In the context of mud mound genesis the functional role of Lithocodium / Bacinella includes baffling and binding, the production of micrite via the calcification inside of mucilaginous sheaths, and via intensive boring activities upon and inside of skeletal hard parts. The mass occurrence of Lithocodium / Bacinella with associated algae and microbes may be explained by a longer ranging eutrophism of the environment or by shifts in seawater carbonate alkalinity.</ABSTRACT>

15491 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 119: 47-61.</SOURCE>
15492 <ABSTRACT>The discovery of a well preserved Lower Cretaceous siliceous sponge community in Islares (Cantabria, north Spain) is documented. Lower Albian sponges crop-out in great abundance as a rich necrocoenosis embedded in a marly matrix. Demosponges make up the bulk of an 11 m thick succession, which is interpreted as having formed in a slope setting. The sponges show body preservation and were buried " in situ". All types of growth forms are present; they grew so tightly that they often fused secondarily. Shape polarity suggests steady low energy, predominantly easterly palaeocurrents. The main factor limiting the community seems to have been space competition. A preliminary documentation of the systematic palaeontology is presented: only taxa from the families Tetracladinidae, Megamorinidae and Corallistidae were found. Geometrical restoration of the platform-basin transect allows estimation of a depth of approximately 40 m for the lithistid sponges. Sea-level variations driven by block-faulting controlled the available accommodation space. Sponges occur just below and above a sequence boundary and are associated with a major tectonic event linked with the opening of the Bay of Biscay.</ABSTRACT>

15516 <TITLE>The phosphatized sponges from the Santonian (Upper Cretaceous) of the wielkanoc Quarry (southern Poland) as a tool in stratigraphical and environmental studies.</TITLE>
15517 <SOURCE>Acta Geologica Polonica 59, 4: 483-504. <http://www.geo.uw.edu.pl/agp/index.html></SOURCE>
15518 <ABSTRACT>Phosphatized sponges from the Santonian of the wielkanoc Quarry are represented by 11 species of Hexactinosida and 16 species of Lychniscosida. The taxonomic composition is most similar to the Micraster coranguinum Zone fauna (Middle Coniacian-Middle Santonian) of England. Three preservational groups of sponges are distinguished: "white"; "beige"; and "dark". They are infilled by phosphatized foraminiferal/foraminiferal-calcisphere wackestone and are contained in the marly calcareous inoceramid packstone. The sponges indicate a calm and relatively deep (> 100m) life environment. After burial, phosphatization and exhumation, the fossil sponges were redeposited in Upper Santonian strata. The "white" and "beige" groups were displaced a very short distance or represent only lag deposits. The rolled and crushed sponges of the "dark" group were exhumed and phosphatized more than once. They could be redeposited (reworked) nearly in the same place and/or transported from some longer distances (but not from outside of the Cracow Swell). The phosphatized wackestone infilling the sponges, and the phosphatized clasts, are the only remains of the deposits, which formed on the Cracow Swell after the late Early Coniacian but before the Late Santonian.</ABSTRACT>

- 15542 <TITLE>Late Cretaceous siliceous sponges from the Middle Vistula River Valley (Central Poland) and their palaeoecological significance.</TITLE>
- 15543 <SOURCE>Annales Societatis Geologorum Poloniae 76, 3: 227-296.BUS7-0001-0058</SOURCE>
- 15544 <ABSTRACT>Siliceous sponges are extremely abundant in the Upper Campanian-Maastrichtian opokas and marls of the Middle Vistula River Valley, situated in the western edge of the Lublin Basin, part of the Cretaceous German-Polish Basin. This is also the only one area in Poland where strata bearing the Late Maastrichtian sponges are exposed. The presented paper is a taxonomic revision of sponges collected from this region. Based both on existing and newly collected material comprising ca. 1750 specimens, 51 species have been described, including 18 belonging to the Hexactinosida, 15 - to the Lychniscosida and 18 - to Demospongiae. Among them, 28 have not been so far described from Poland. One new genus Varioporospongia, assigned to the family Ventriculitidae Smith and two new species Varioporospongia dariae sp. n. and Aphrocallistes calciformis sp. n. have been described. Comparison of sponge fauna from the area of Podilia, Crimea, Chernihov, and Donbas regions, as well as literature data point to the occurrence of species common in the analysed area and to the basins of Eastern and Western Europe. This in turn indicates good connections between particular basins of the European epicontinental sea during the Campanian-Maastrichtian. Analysis of the taxonomic composition of the Middle Vistula assemblage suggests that the occurring sponge fauna is transitional between the faunas of Eastern and Western Europe, what may be linked with the central location of the Lublin Basin in the European epicontinental sea. The gradual upward decrease of taxonomic diversity of the Hexactinosida and Lychniscosida in the studied succession points to gradual basin shallowing, what is consistent with the global regressive trend by the end of the Cretaceous. The domination of the Hexactinellida over the lithistids in terms of diversity and abundance in the entire section allows us to estimate the maximum depth of the Late Campanian basin as 200-250 m and to constrain the minimum depth during the latest Maastrichtian as about 100 m.</ABSTRACT>

15557 <ABSTRACT>The studied field area is located in northern Spain in the Álava province south of the town of Vitoria-Gasteiz. In this region the Tertiary Ebro Basin is accompanied by a small mountain chain named the Sierra de Cantabria. In this mountain chain the southern part of the Penacerrada salt diapir was mapped at 1:10000 within a 6.1 km² sized area. During the Lower Cretaceous, sedimentation was dominated by input from a deltaic shelf. After a first delta phase a small scale marine ingression occurred. During the first diapiric uprising of the Upper Triassic evaporites, a small patch reef complex was formed until lower Aptian times. With the breakthrough of the diapir, coral growth stopped. The second delta phase (Reitner & Wiedmann 1982) started from Albian times with sand and conglomerate deposits. [from the abstract, shortened; some early Cretaceous corals are depicted; Loeser]

15570 <ABSTRACT>A locality close to the autobahn 2 close to Gelsenkirchen in the northwest Ruhr area (SW Münsterland) is reported under stratigraphic aspects. The Late Santon transgression could be correlated with the Recklinghaeuser Sandmergels on the base of the occurrence of the crinoid *Uintacrinus socialis* for the first time. In the fossil list, the coral *Micrabacia coronula* is mentioned from the base of the Late Santonian</ABSTRACT>

15594 <TITLE>Aufbau und Genese eines Slope Mud Mounds aus dem Mittelalb von La Gandara (Nordspanien).</TITLE>
15595 <SOURCE>Berliner geowissenschaftliche Abhandlungen A106: 243-265.

- 15596 </SOURCE>
<ABSTRACT>within the Urgonian facies from the middle Albian of La Gandara, micritic mud mounds occur on the slope of a carbonate platform constructed of rudists and scleractinian corals. The mud mounds are mainly constructed of floatstones and boundstones formed by lithistid sponges and crusts of cyanobacteria and other autotrophic organisms. The mound is located on the weakly dipping margin of the rudist carbonate platform. The margin of the rudist platform is built up by layers of platform debris which are fixed by *Bacinella irregularis* and *Lithocodium aggregatum*. The rudist carbonate platform progrades over the sponge mud mound. On the former southern margin of the mound the platform debris are settled by coralline algae, corals, stromatoporoid chaetetids and other sponges. On the northern part of the buried mound a deltaic environment was established. Reef biota are not observed within this particular environment.</ABSTRACT>

- 15621 <SOURCE>Coral Research Bulletin 06: 1-139.</SOURCE>
15622 <ABSTRACT>During the Late Mesozoic, thick successions of marls and limestones were sedimented. The basin was situated at the northern margin of the Iberian Peninsula and its formation was influenced mainly by the opening of the Bay of Biscaya in the northwest. During the Aptian homoclinal carbonatic ramps were developed with biohermal buildups mainly of rudists and corals. Parts of the ramps were preserved in the Boixols thrust sheet, which is situated in the central Catalanian Pyrenees, in the middle part of the Segre valley. Biostratigraphical indications showed that the carbonate ramps were of Upper Aptian age. Selected sections provided data on the sedimentology, microfacies and palaeontology of the ramp. The development of the facies and fossil assemblages is described. The formation of bioconstructions is discussed in detail. The association of corals and rudists shows clear distribution patterns of middle and inner ramp

areas. whilst rudists lived on the shallowest parts of the ramp, corals preferred slightly deeper environments. In ranges of a changing sedimentation rate, corals and rudists settled in the same area. Corals show three types of colonization: shallow coral meadows, lens-shaped biostromal buildups and coral banks (bound-and-rambles). Their various morphotypes indicate a clear adaptation to soft bottoms and changing sedimentation rates. The formation of bioconstructions is mainly due to regional factors, less to global ones. For two time spans (Senyis and Font Bordonera Formation), palaeogeographical reconstructions are provided. Based on the microfacies and the distribution of fossils, the sea level changes in the Basin of Organya are documented. [part of extensive summary] </ABSTRACT>

15634 <SOURCE>Vestnik Ceskeho geologickeho ustavu 72, 1: 83-100.</SOURCE>

15635 <ABSTRACT>The Velim locality represents a prime example of a nearshore sedimentary environment of the Cenomanian-Turonian boundary interval, in the Bohemian Cretaceous Basin. This extraordinary locality highlights the rocky-bottom morphology with its distinct lithology; carbonate microfacies; clay mineralogy; phosphates; and macrofaunal characteristics. Eight geological sections represented by depression fillings and rocky-bottom coverings, were studied. Micropaleontological studies, discussion and interpretations are included into a second paper (same journal).</ABSTRACT>

15646 <TITLE>Rocky coast facies of the Unhost'-Tursko High (late Cenomanian-early Turonian, Bohemian Cretaceous Basin).</TITLE>

15647 <SOURCE>Acta Musei Nationalis Pragae (B) Historia Naturalis 54, 3/4: 79-116.</SOURCE>

15648 <ABSTRACT>A study of the Late Cretaceous rocky coast deposits of the Unhost'-Tursko High lying west-northeast of Prague is undertaken here. Based on the record of the rocky bottom characters, overlying sediments, phosphates, distribution of foraminifers, palynomorphs and macrofaunal taphocoenoses, two sedimentary settings each with its own phosphogenesis have been distinguished. The phosphogenic products are in part reworked and redeposited into younger beds. The older phosphatic remains are reported from the conglomerate in which the taphocoenose with *Gisilina? rudolphi* and *Goniopygus cf. Menardi* occurs. Parts of the two sections (Predboj and Cernovicky) characterized by this taphocoenose belong to the upper part of *Metoicoceras geslinianum* Zone and are discussed here in more detail. The younger phosphogenic episode is probably of the early Turonian age. Both the proper

phosphogenic episodes and subsequent development of strata are correlated with the updip succession of the Pecinov Member and the Bila Hora Formation in the Pecinov quarry. The palaeoenvironments of principal intervals are briefly discussed to elucidate problems of phosphogenesis and distribution of faunal remains.</ABSTRACT>

15659 <TITLE>Cenomanian / Turonian sponge microbialite deep-water hardground community (Lienres, northern Spain).</TITLE>

15660 <SOURCE>Facies 32: 203-212.</SOURCE>

15661 <ABSTRACT>A benthic community of sessile metazoans dominated by coralline sponges (e.g. Acanthochaetetes and Vaceletia) is found within a Cenomanian-Turonian deep water hardground succession cropping out at the coastal area of the Bay of Biscay near Santander. The characteristic K-strategic community exhibits a very close taxonomic relationship with modern communities from the Pacific realm, which allows for a comparison with Recent environmental conditions. The sponge community was associated with automicrites, microbialites, and thin mineralized limonitic biofilms. This biofacies is typically found in cryptic niches of reefal buildups ("telescoping"). The iron-rich biofilms had a strong electrochemical corrosive ability which explains the distinct submarine dissolution patterns. The hardground conditions are controlled, in part, by strong contour current regimes linked with extremely oligotrophic water masses. This system was established during the drowning of a distal carbonate ramp during the early Middle Cenomanian (A. rhotomagense zone). In the uppermost portion of the hardground (Late Cenomanian, upper R. cushmani zone) the coralline sponge community was replaced by thick limonitic stromatolites with numerous encrusting foraminifera (Miniacina-type) and by colonies of the problematic iron bacterium Frutexites. This event is accompanied by an increase of terrigenous influx and detrital glauconite, indicating a fundamental change in food web, and terminates the sponge dominated basal hardground interval. The hardground was buried by hemipelagic sediments during the Middle Turonian (upper R. kalleesi zone).</ABSTRACT>

15711 <TITLE>Low sedimentation rate aphotic shelves with Dendrophyllia and sponges - Bartonian of the easternmost sector of the Ebro Basin.</TITLE>
15712 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 265-273.</SOURCE>
15713 <ABSTRACT>Large surfaces colonized by sponges occur among Bartonian shelf deposits (Vie Marl Fm.) in the NE sector of the Ebro Basin. Sponges developed in the aphotic zone during periods of low sedimentation rate. These surfaces are overlain by bioclastic accumulations almost exclusively composed of remains of the coral, Dendrophyllia. These remains are in a calcareous mud, siliciclastic silt and sand matrix. Pollen/spore dinoflagellate ratios are similar

both in Dendrophyllia packstones, wackestones and sandy deposits and in sponge-colonized surfaces. Dendrophyllia "in situ" are not preserved. We interpret these deposits as corresponding to the accumulation of Dendrophyllia corals periodically eroded from hard substrates by high density/low viscosity currents. The features of these deposits suggest them to be the deepest shelf environments recorded in this sector of the Ebro Basin.</ABSTRACT>

15816 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 297-304.</SOURCE>
15817 <ABSTRACT>At the margins of the Tertiary Ebro Basin an alluvial-fan complex is well developed with an abundant and diversified marine fauna. Good reef bodies were developed and adapted to deltaic lobe paleogeography, associated with deltaic system progradation. This paper describes five new upper Eocene coral species from Igualada, in the western margin of the Ebro basin. This coral fauna has been dated as Bartonian. The coral fauna is notably diverse, with 43 and 35 species. (Alvarez 1993). The new coral species from Igualada are: Stylocoenia aurelii, Acropora bancelisae, Hariosmilia gasseri, Hariosmilia viai (all these can be found in back reefs of patch- and fringing-reefs and Desmophyllum castellolense (anchored in the sediment and dominant in marls with scarce corals).</ABSTRACT>

15906 <TITLE>Eine neue Poriferen-Fauna aus dem Septarienton (Oligozan, Rupelium) von Bad Freienwalde (NE-Deutschland) und der erste fossil erhaltene Vertreter der nicht-rigiden Hexactinelliden-Gattung Asconema.</TITLE>
15907 <SOURCE>Paläontologische Zeitschrift 77, 2: 263-280.</SOURCE>
15908 <ABSTRACT>The hexactinellid sponge fauna, which is described here for the first time, originates from the "Septarienton" (Rupelium, Oligocene) of the "Kirchenziegeleigrube" near Bad Freienwalde (NE Germany). This fauna includes lyssacinosan, as well as hexactinosan species, represented by Asconema oligocaena n.sp. (Hexasterophora, Lyssacinosa), the first occurrence of this genus from the fossil record, Aphrocallistes sp. (Hexasterophora, Hexactinosa), and Hyalonema sp. (Amphidiscophora). The three-dimensional, pyritic body-preservation of these non-rigid sponges suggests fossilization by rapid burial. Episodic mudflows are suggested to be responsible for this. The environment of deposition is suggested to have been a moderately shallow shelf, possibly in the distal range of a delta, characterised by relatively low sedimentation rates and no turbulence, except when disturbed by episodic mudflows. Low energy conditions are a precondition for the settlement of the described Hexactinellida. [original English abstract]</ABSTRACT>

15919 <TITLE>Biofacies of the outer continental shelf in the Bartonian of the Eastern part of the Ebro Basin (NE Spain).</TITLE>
15920 <SOURCE>Boletín de la Real Sociedad Española de Historia Natural, Sección Geológica 92, 1/4: 249-256.</SOURCE>
15921 <ABSTRACT>The thick marly deposits of the Bartonian of the Vie area are very rich in various benthic fauna. The analysis of this fauna,

especially sponges, bryozoans and larger foraminifera allows these deposits to be interpreted as having been laid down in a deep, outer shelf setting. It is possible to distinguish in these deposits two groups of biofacies, euphotic and aphotic respectively. The biofacies of the deep euphotic shelf are characterized by the alternation of marls and marly limestones, and include abundant siliceous sponges, but also larger foraminifera, brachiopods, bivalves and crustaceans among other fauna. The fauna of the marls is less diverse and is represented almost exclusively by bryozoans. The deposits of the aphotic shelf are composed of marls, and different biofacies may be distinguished: small bryozoan bioherm biofacies; bryozoan mud mound biofacies; siliceous sponge bed biofacies, and siliceous sponge and ahermatypic coral bed biofacies. The sponge fauna is dominated by hexactinosan and lychniscosan sponges, but other hexactinellids are also present. The detailed characteristics of other faunal elements common in particular biofacies and the interpretation of each biofacies are also discussed.

15932 <TITLE>Structural and faunal evolution of Chattian - Miocene reefs and corals in western France and Northeastern Atlantic Ocean.</TITLE>

15933 <SOURCE>Concepts in Sedimentology and Paleontology 5: 105-127.</SOURCE>

15934 <ABSTRACT>Chattian and Miocene coral reefs and faunas of the western France basins are reviewed within a paleogeographic context. Several new outcrops have been discovered, and extensive new and historic collections have been studied. Coral diversity was very high in the Aquitaine basin during the Chattian(1) (ca. 150 species) and a little less so during the Early Miocene (110 species); during these times, relatively small reefal buildups formed in a tropical climate. The Mid-Miocene coral faunas show a marked decrease in diversity (some 75 species in all), with "subreefal" facies in the Langhian of southwestern and northwestern France. The Upper Miocene fauna is even poorer (just about 20 species) and only known in northwestern France. Throughout the Miocene, the proportion of hermatypic taxa also decreased notably; in the coral assemblages, these species were strongly predominant from Chattian to Burdigalian. Afterwards, the ahermatypic taxa became progressively predominant. Other northeastern Atlantic areas (Portugal, Morocco) are also investigated. Some biogeographic data sketch the evolutionary trend of these coral communities. During the Chattian, an (eastern and western) Atlantic-Mediterranean bioprovince was differentiated. During the Early Miocene, this bioprovince was restricted to eastern Atlantic and Mediterranean. From the Mid-Miocene, the coral faunas were disconnected from the Mediterranean, and an impoverished eastern Atlantic bioprovince became established without real renewal. A comparison with Mediterranean reefs shows that maximum coral building took place within the Mid-Miocene in the Mediterranean realm (with continuation of reefs in the Late Miocene), instead of Chattian (and Early Burdigalian) as in the Atlantic areas. Tortonian-early Messinian of the Lorca Basin, SE Spain.</TITLE>
15959 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 213: 163-185.
</SOURCE>
15960 <ABSTRACT>Coral reefs represent on of the main carbonate factories that
contributed to the control of stratigraphic architecture of carbonate
platforms, which had a widespread development during the late Miocene
in the paleo-Mediterranean area. The late Miocene reef complexes of the
Lorca basin in southeastern Spain are composed of five mixed
siliciclastic/carbonate units, middle Tortonian to early Messinian in
age. The development of coral reefs probably ceased when the first
evaporite event occurred in the basin centre in the early Messinian.

15971 <TITLE>The Lower Badenian (Middle Miocene) coral patch reef at Grobie
(southern slopes of the Holy Cross Mountains, Central Poland), its
origin, development and demise.</TITLE>
15972 <SOURCE>Acta Geologica Polonica 52, 4: 521-534.</SOURCE>
15973 <ABSTRACT>The Lower Badenian (Middle Miocene) patch reef of Grobie
(southern slopes of the Holy Cross Mountains, Central Poland) is the
only coral buildup in the Polish Miocene. It contains four hermatypic
coral taxa, of which *Tarbellastraea reussiana* (Milne Edwards &
Haime) and *Porites collegniana* Michelin dominate, whereas *Montastraea*
sp. and *Stylophora reussiana* Montanaro-Gallitelli & Tacoli are
subordinate. wide diversities of colony shapes in this coral
nassemblage reflect natural development of the reefal structure and/or
energy of environment; it varies from platy colonies (first settlers on
an unconsolidated, pebble.strewn substrate), through branching, to
massive forms. Wave activity was the most significant factor that
influenced the reef core and distribution of associated facies.

Disintegration and removal of reef core sediment led to the formation of crack crevices in freshly lithified deposits. Redeposited sediment formed the back-reef talus, where its composition varied with distance from the reef core. Reef-associated molluscs and decapods are abundant, the bivalves being represented by high-energy resistant borers (*Lithophaga* sp., *Jouannetia* (J.) *semicaudata* Des Moulins) and the squatter *Sphenia* (S.) *anatina* (Basterot). Among 21 decapod taxa, the species *Dardanua hungaricus* (Lorenthey, 1929) is reported from Poland for the first time. Recognition of the diversity of facies and their distribution enabled reconstruction of Grobie area during the Early Badenian transgression. Slowing and/or stopping of sealevel rise encouraged development of the patch reef, while the subsequent, rapid transgression pulse caused its demise. Shortly after all reefal deposits were buried, diagenetic processes of neomorphisation and/or dissolution of aragonitic skeletal elements took place. This diagenesis could have continued till the Late Miocene and Pliocene, synchronously with rapid erosion that progressed since the Early Sarmatian until the Pleistocene glaciation.

15997 <TITLE>Les faunes de scléractiniaires dans les faluns du Miocene moyen d
'Atlantique-Est (bassins de la Loire et d'Aquitaine):
paléobiogéographie et évolution climatique.</TITLE>
15998 <SOURCE>Annales de Paleontologie 91, 1: 33-72.</SOURCE>
15999 <ABSTRACT>The Aquitaine and Loire basins show in the Middle Miocene numerous marine littoral deposits, often shelly or crag-type. Scleractinia are present, with a distribution and an abundance very variable according to the outcrops. A detailed study of all the available material, recently or historically cropped, allowed to draw up an accurate faunal inventory and to compare the distribution of taxa between the two basins. Out of 90 taxa in total, 62 are known in Aquitaine and 48 in Loire. In the Aquitaine Langhian, when is noted an obvious reduction of hermatypic taxa in comparison with the rich regional Burdigalian faunas, the association includes 44 species (25 reef-building ones). In the Serravallian, the reef-building taxa become significantly scarce and are residual (9 taxa out of 33 in Aquitaine, present in levels belonging to the lower sequence of the stage, and located in sheltered internal parts of the south-Aquitaine and central-Aquitaine gulfs). In the Loire basin, the corals are quite diversified in the Pontilevian facies (19 reef-building taxa out of

48), and much scarcer in the Lublean and Savignean facies. Globally, the Scleractinia are few abundant everywhere. If in the two basins hermatypic taxa persisted in the Langhian, indicating subreefal type facies, varied factors have impeded permanently the settlement of reefs. In comparison with the Burdigalian, the thermic deterioration gradient, evidenced since the Chattian on the northeastern Atlantic frontage, had an important influence, and the Langhian waters were only subtropical. Other factors acted, at least locally, as the hydrodynamics, the bathymetry, the kind of substratum, the salinity proparte. Moreover, a latitudinal gradient between the two basins is evidenced by the global species richness and by the ratio of hermatypicity, created here and defined as the fraction of hermatypic taxa reported to ahermatypic ones from a same basin. This ratio can be used at generic level or specific one as well. In the Serravallian, when the diversity was everywhere obviously lower, the influence of the climatic gradient went on, together with other unfavourable conditions (often abundant detritic supplies, high hydrodynamics, spatial biocompetition). Diverse biogeographic and paleogeographic data are also reported. A vast East-Atlantic coralline bioprovince, settled as early as the Chattian with a dispersion center located in Aquitaine, was still active in the Middle Miocene, when large transgressions favoured the faunal exchanges; its history was to be completed at the end of this period.

16011 <SOURCE>Geobios 32, 1: 33-62.</SOURCE>

16012 <ABSTRACT>An abundant fauna of Scleractinian corals has been studied from a Mid Miocene (Serravallian) new outcrop in the North Aquitaine Basin (SW France). It consists of more than fifteen taxa, with a noticeable diversification in the genera Flabellum and Balanophyllia; 10 of these taxa are new in the Miocene of the Aquitaine Basin. This is probably the richest assemblage of the French Serravallian. The name Flabellum montanaroe nov. nom. is set. Biogeographically, the studied locality bears witness to Northern, Atlantic and Mediterranean influences. The ahermatypic content of the fauna agrees with the observed general trends to a gradual disappearance of reefal species and to a cooling in neritic waters during the Mid Miocene along the Northeastern Atlantic frontage. In terms of paleoecology, the corals-rich deposit contains an abundant malacofauna, which indicates an infralittoral, euhaline, and fairly calm environment, with a marly-sandy substrate; this biofacies looks like the muddy facies of the modern assemblage SFBC ("Sables Fins Bien Calibré+M1324s").</ABSTRACT>

16064 <ABSTRACT>Tortoflabellum sp. occurs in the Lanzendorf series (" Lower Tortonian") of Borac near Brno (Moravia). This species has a prominent tabularium, hitherto not known from any member of the family Flabellidae. Tabulae are formed by centripetal growth within interseptal chambers.</ABSTRACT>

16088 <TITLE>The regeneration in some caryophyllid corals from the Korytnica
Clays (Middle Miocene; Holy Cross Mountains, Central Poland.)</TITLE>
16089 <SOURCE>Acta Geologica Polonica 34, 3-4: 213-221.</SOURCE>
16090 <ABSTRACT>A common case of regeneration from very small fragments
(composed even of those containing at least one entoseptum) is reported
in some scleractinian corals coming from a specific,
solitary-coral-dominated community of the near-to-shore facies of the
Korytnica Clays (Middle Miocene, Badenian; Holy Cross Mountains,
Central Poland). It concerns the specifically indeterminable
caryophyllids, some individuals of which underwent regeneration twice.
The regeneration itself (growth from tiny fragments of the primary
individual) is discussed in its relation to the reparation (a repair of
an injury within the animal's skeleton). The whole population of
the regenerated caryophyllids, which dominated a near-to-shore
community within the Korytnica Basin, characterizes by the size
distinctly smaller than that of normal individuals. This event is
compared to that recognized in some populations of the present-day and
ancient free-living bryozoans, those inhabiting the Korytnica Basin
including. In both these groups (caryophyllid corals, and free-living
bryozoans) the regeneration is discussed as an important mean of some
selected reproduction of these species, and as an immanent biological
feature of some selected taxa. (Original summary)</ABSTRACT>

16128 <SOURCE>Acta Geologica Polonica 35, 1-2: 89-155.</SOURCE>
16129 <ABSTRACT>The reefs are built mostly of laminar crusts of coralline algae, shells of sessile gastropods *Petalocochus intortus* (Lamarck), and of detrital internal sediments. The secondary encrusters of a reef frame are bryozoans, serpulids, foraminifers and cirripedes *Verruca*. Seven species of coralline algae are common among 21 species found in reef deposits. Corallines show most species in common with the Ukraine and only some with the Vienna Basin.</ABSTRACT>

16192 <TITLE>Une faune de fond dur du bathyal supérieur dans le Miocène terminal des Cordillères Bétiques (Carboneras, SE Espagne).</TITLE>
16193 <SOURCE>Mesogée [Bulletin du Museum d'histoire naturelle de Marseille] 51: 3-13.</SOURCE>
16194 <ABSTRACT>The Carboneras area is located at the NE of the Miocene volcanic massif of Cabo de Gata. The red breccia is an olistostrome that resulted from mass sliding, in bathyal environment, of a large volcanic structure, in which fissures opened by traction. The fissures preserved an upper bathyal hard ground fauna, and foraminiferans indicating a Messinian age. The fauna is remarkable by its diversity, comprising notably calcified sponges, stylasterids, scleractinians, gorgonians (Isididae, Primnoidae, Corallium), various gastropods (some of them living associated with corals), stalked crinoids. Various genera that seem to be faunal elements from Tethys, no longer exist in the Mediterranean and the NE Atlantic. With at least 14 species in at least 8 genera, the stylasterids from Carboneras are the most diversified fossil assemblage presently known of this group, and comparable to Recent upper bathyal faunas of the Indo-Pacific (e.g.

of New Caledonia). Three types of stylasterid symbionts, or their traces, have been recognized: the gastropod *Pedicularia*, a polynoid polychaete and a siphonostomatoid copepod, the two latter causing characteristic galls. Polynoid galls have also been found on *Corallium*, and an ascothoracid gall (of the *Isidasculus* type) on an isidid gorgonian (the latter from the marls of La Atalaya de Mazarron, a deposit of similar age).</ABSTRACT>

16219 <SOURCE>Sedimentary Geology 107: 61-81.</SOURCE>

16220 <ABSTRACT>As suggested by the title, we report the changes in depositional geometries of a prograding Messinian fringing reef in response to sea-level oscillations. Two orders of sea-level cyclicity are reflected in upward and downward shifts of reef facies. During lowstands no reef growth took place. Deduced sea-level changes are of magnitudes similar to the ones recognised in the Quaternary.</ABSTRACT>

16245 <SOURCE>Acta Geologica Hispanica 15, 4: 97-104.</SOURCE>
16246 <ABSTRACT>Excellent exposures in Cabo de Gata area reveal two major Messinian depositional sequences, the Reef Complex and the Terminal Complex, which are overlying a complicated erosional morphology with several terraces on the volcanic basement. A typical Porites reef developed on the 200m platform and originated extensive fore slope deposits adosed to the terraced volcanic basement. This Reef Complex is severely truncated by an important erosion surface, which also presents a terraced morphology (80, 160, 220m) and follows similar trends than the erosion surface on the volcanic basement. This intra-Messinian erosion surface is onlaped by the Terminal Complex, consisting in alternating layers of oolites, stromatolites and Porites thickets. Hypothetically, layers of evaporites could had been associated to the stromatolites in the lower section of the Terminal Complex before the pre-Pliocene erosional episode. 16374 <TITLE>Oberjurassische Korallen-Geschiebe (Thamnasteria concinna) aus einer Kies-/Sandgrube bei Freden/Leine (Leinebergland).</TITLE>
16375 <SOURCE>Mitteilungen aus dem Geologischen Institut der Universitat Hannover 38: 115-121.</SOURCE>
16376 <ABSTRACT>Upper-Jurassic geschiebe-corals (Thamnasteria concinna) from a gravel-/sandpit at Freden/Leine are described. They are slightly bored by bivalves (Gastrochaenolites) and worms (Trypanites). Some oysters (Nanogyra) encrusted the surface. The corals grew as massiv head-like (bulbous) colonies in a "multicolumnar growth form" with a ragged outline. Similar shaped colonies are reported from East-European Upper Jurassic (Pomerania), but are never reported from NW-Germany. Beds in which the coral-geschiebe were found - Drenthe stage in age - contain a high content of local geschiebe material. The

- low degree of abrasion of the coral-geschiebe indicates short glacial transportation. It is possible, that the drift material originates from the Heersumer Schichten from Selter to Thiister Berg. [modified abstract]

16413 <TITLE>Les Formations du Devonien moyen de la Belgique.</TITLE>
16414 <SOURCE>Memoires pour servir a l'Explication des Cartes Geologiques et Minieres de la Belgique 30: 1-106.</SOURCE>
16415 <ABSTRACT>The authors present proposals to standardize the subdivision into formations of the Middle Devonian strata of the Dinant Synclinorium, the Namur Synclinorium and the Vesdre Massif. They recognize ten formal formations, and one informal, in the Couvinian (uppermost Emsian and Eifelian) and the Givetian strata of the southern flank of the Dinant Synclinorium. These formations are from older to younger : the St.-Joseph Fm, the Eau Noire Fm, the Couvin Fm, the Jemelle Fm, the Lomme Fm, the X Formation at Wellin, the Hanonet Fm, the Trois-Fontaines Fm, the Terres d'Haurs Fm, the Mont d'Haurs Fm and the Fromelennes Fm. The Middle Devonian

succession of the northern flank of the Dinant Synclinorium and of the southern flank of the Namur Synclinorium comprises the Riviere Fm, the Nevremont Fm and the Le Roux Fm. On the northern flank of the Namur Synclinorium, the Middle Devonian is represented by the Bois de Bordeaux Fm. In the Middle Devonian succession of the Vesdre Massif, the authors recognize the Vicht Fm, the Pepinster Fm, the Nevremont Fm and the Le Roux Fm. The authors describe and figure a stratotype and, in some cases, an other reference section for each formation. Lateral changes and age of the formations are also discussed. </ABSTRACT>

16440 <SOURCE>Bulletin de la Societe belge de Geologie 103, 1-2: 171-203.</SOURCE>
16441 <ABSTRACT>The Glageon quarry in northern France is situated west of the classical Givetian outcrops on the southern margin of the Dinant Synclinorium. Because of its location and the excellent outcrop, a detailed sedimentological and paleontological study has been carried out. Sixteen carbonate microfacies, ranging from open marine to supratidal environments have been described. The Terres d'Haurs, Mont d'Haurs and Fomelennes Formations are relatively similar to their equivalents from the Givet type area. However, the Trois-Fontaines Formation is partly different, due to the absence of a lagoonal complex above the first biostrome. Sequential analysis shows that sedimentation is controlled by three orders of paleobathymetric cycles. The diagenetic sequence has been established. The burial diagenesis is very important, after a brief distal meteoric cementation phase.</ABSTRACT>

16491 <TITLE>Depositional Models and Sequence Stratigraphy of Non-Tropical Carbonates: The Miocene of the Agua Amarga Basin (SE Spain).</TITLE>
16492 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
16493 <ABSTRACT>The lower Tortonian and upper Tortonian / lower Messinian carbonates of the Agua Amarga Basin in Southern Spain (Prov. Almeria)

provide examples for neritic non-tropical, Mediterranean-type carbonates, which occur alternating with subtropical to tropical chlorozoan reefs. The carbonate factory of the non-tropical depositional systems was situated in a shallow water area around wave base. Main carbonate producing organisms were nodular and robust bryozoans, bivalves, and red algae. We demonstrate that sequence stratigraphy of these non-tropical carbonates markedly differs from the established sequence stratigraphy models of tropical carbonates. The non-tropical carbonate depositional sequences display many features of siliciclastic depositional sequences. In addition, we show that the intrinsic link of surface water temperature fluctuations and sealevel changes has a high potential to shape carbonate depositional sequences.

16506 <ABSTRACT>A first supplement on the Catalogue of Holotypes housed in the Geological Museum of Seminary of Barcelona is offered. The first Catalogue was issued in 1992 and 148 new taxa are listed here. Mainly these new taxa are dealing with Scleractinia, Gastropoda, both from Cretaceous until Eocene, Miocene Crustacea, Bryozoa, etc. Some new data and opinions concerning several taxa erected before 1992, are given.

16517 <TITLE>Der Glimmerton-Aufschluß Gross Pampau (Herzogtum Lauenburg / N Germany; Langenfeldium, Obermiozaen), seine Entwicklung und Fossilfuehrung.</TITLE>

16518 <SOURCE>Geschiebesammler 27, 4: 143-183.</SOURCE>

16519 <ABSTRACT>Es wird ueber die zeitliche Entwicklung und die Fossilfuehrung in den Aufschluessen Gross Pampau I und II mit 65 bisher hier nicht beobachteten Molluskenarten, 2 Korallenarten, 10 Knorpelfischarten, 16 Knochenfischarten und ueber einige Walreste berichtet und diese teilweise abgebildet. Aus den neuen Fundergebnissen werden die stratigraphisch-palaeoekologischen Folgerungen diskutiert. Die Korallenfauna. Massenhaft tritt die kleine Einzelkoralle Ceratocyathus granulatus (Goldfuss 1826) auf und vereinzelt finden sich sehr groe Exemplare von Flabellum vaticani Ponzi 1876, beschaenkt auf die unteren Lagen von Gross Pampau II. Besonders E. vaticani, bekannt nur aus dem mediterranen Raum und aus dem Mittelmiozaen des Nordseebeckens wie Twistringen und Dingden, die hier eine Kelchbreite von 5cm erreichen, kommt in Gross Pampau II in sehr grossen Exemplaren mit ueber 10cm Kelchbreite vor. Offensichtlich hatte diese Art hier optimale Lebensbedingungen! Besonders die Wassertemperatur, aber natuerlich auch

- Licht, Reinheitsgrad des Wassers und ein gutes Nahrungsangebot sind entscheidend fuer gutes Wachstum. Welche Wassertemperaturen sind im Obermiozaen zu erwarten? Am Niederrhein wird mit einem Mittelwert von 15° C im festlandischen Obermiozaen gerechnet. [extracted from original paper]

16584 <ABSTRACT>Prof. F.F. Steininger und Dr. U. Jansen vom Forschungsinstitut Senckenberg versuchten deshalb seit 1998, die deutschen paläontologischen Sammlungen systematisch zu erfassen, wobei reine Privatsammlungen natürlich nicht berücksichtigt werden konnten. Die vorliegende Schrift stellt die erste Auswertung der gesammelten Daten dar. Ihr Zweck besteht darin, die Situation der paläontologischen Sammlungen in Deutschland darzustellen. Die Liste soll der Politik und der Öffentlichkeit vor Augen führen, wo finanzielle, technische und personelle Hilfen nötig sind. Die Auflistung der Daten repräsentiert zugleich eine Informationsquelle für den Geowissenschaftler zur Lokalisierung bestimmter Sammlungen und Sammlungsobjekte. 16634 <TITLE>Sequence stratigraphy of the Belgian Lower Carboniferous - Tentative correlation with the British Isles.</TITLE>
16635 <SOURCE>Canadian Society of Petroleum Geologists, Memoir 19: 41-51.</SOURCE>
16636 <ABSTRACT>The Lower Carboniferous of southern Belgium (Dinantian Subsystem) is well documented and serves as reference for the Tournaisian and Viséan Series. Hundreds of sections and boreholes were measured bed by bed and collected for faunas. Biostratigraphy relies mainly on information on foraminifers, conodonts and corals, but most of other fossils groups typical of platform carbonates are abundant and diversified. Despite this great amount of data, many correlations remained questionable, mainly due to rapid facies changes and scarcity of fossils in some levels. During the Tournaisian and the Lower Viséan, these changes are related to the facies evolution from nearshore to outer shelf with building of a distant Waulsortian barrier during Upper Tournaisian. Moreover, extensional synsedimentary faulting during Lower Viséan, have played a major role, controlling subsidence and facies distribution. During Middle to Upper Viséan (up to the base of the Upper Warnantian), spectacular cyclothemic sedimentation developed over a large area, reflecting a quite regular paleotopography, that later reduced in surface under the influence of the early phase of Variscan deformation. The uppermost part of the Viséan was not deposited. Re-evaluation of the former Dinantian biostratigraphical pattern in a sequence stratigraphical approach gives new insight, particularly for the Tournaisian-Viséan transition. From the base of the Tournaisian to the base of the Upper Warnantian (=Brigantian), 9 third-order sequences have been recognized in southern Belgium. Most of the lowstand systems tracks (LST) are lacking, probably because the high rate of eustatic variation exposed of the

studied areas. One of the most striking events is the important sea level fall followed by a relatively low rise, at the time of the T-V transition, with deposition of the transgressive systems tract (TST) and the highstand systems tract (HST) of a third-order sequence (sequence 5, corresponding to most of the Soviet Formation) only in the deeper part of the outer shelf. The recognition of this sequence and of its corresponding stratigraphic gap on the shallow shelf allows a better understanding of the T-V boundary and, therefore, merited reinvestigation (Devuyst, XIV ICCP). The duration of the Dinantian third-order sequences are variable, including different amounts of parasequences (fourth and fifth order) and resulting in the variable thickness of the sequences. Several sequences defined here have been recognized in the Bristol area of England and are more tentatively correlated with the cycles of Ramsbottom (1979) established for the Lower Carboniferous of Great Britain. These however do not correspond exactly with the third-order sequences. </ABSTRACT>

 16673 <TITLE>Correlation of Uppermost Carboniferous and Lower Permian Rugose Coral Zones from the Urals to Western North America.</TITLE>
 16674 <SOURCE>Palaios 11, 1: 71-82.</SOURCE>
 16675 <ABSTRACT>More than 40 species of uppermost Carboniferous and Lower Permian rugose corals collected from 5 areas on the Russian Platform and the Ural Mountains permit eight coral zones to be erected. They are

the (1) *Timania dobroljubovae* zone, (2) *Arctophyllum minimum* zone, (3) *Ferganophyllum* sp.nov. 1 zone and its analogue in Timan, the *Timania* sp. 1- *Heritschioides* aff. *H. carneyi* zone, (4) *Kleopatrina* (K.) *pseudoelegans*-*Tschussovskenia captiosa* zone and its partial analogue in Timan, the *Lophbillidium* zone, (5) *Timania schmidti*-*Kleopatrina* (K.) *magnifica* zone, (6) *Protolonsdaleiastraea biseptata* zone, (7) *Protolonsdaleiastraea longiseptata* zone, and (8) *Protolonsdaleiastraea juresanensis* zone. Several of these zones can be extended to Spitsbergen and North America. Especially important for international correlation are four levels at which major changes in the assemblages of rugose corals occur. These are (1) at the base of the *Timania dobroljubovae* zone, (2) at the base of the *Kleopatrina* (K.) *pseudoelegans*-*Tschussovskenia captiosa* zone, (3) at the base of the *Protolonsdaleiastraea biseptata* zone, and (4) at the top of the *Protolonsdaleiastraea juresanensis* zone. </ABSTRACT>

16686 <TITLE>Famennian and Tournaisian recoveries of shallow water Rugosa following late Frasnian and late Strunian major crisis, southern Belgium and surrounding areas, Hunan (South China) and the Omolon region (NE Siberia).</TITLE>

16687 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 154, 1-2: 11-26.</SOURCE>

16688 <ABSTRACT>The Rugosa remained almost totally absent from the platform environments of southern Belgium and surrounding areas, Hunan and Omolon during the long time interval between the end-Frasnian crisis and the early part of the late Famennian (marginifera Zone), probably owing to cool climatic conditions. They first appear in the Upper marginifera Zone, but are uncommon and poorly diversified. Few of them belong to pre-Famennian genera. It is only near the beginning of Strunian time that rugose corals radiated and became common. Their morphological and allometric variabilities were very large, indicating their high potential for adaptation to free niches. This first radiation was abruptly terminated by an extinction event, and a second radiation quickly began, mainly from new taxa and only from a few previously known ones. In western Europe and in Hunan, this second radiation was also stopped abruptly, while species were evolving, by the Hangeberg event at the end of the Strunian. In Omolon, where the position of the Devonian-Carboniferous boundary is doubtful, the second radiation may have been completed before the end of the Strunian, and probably the corals affected by the end-Famennian event were new ones, resulting from a third radiation. In the three regions and at each recovery, the rugose corals are endemic, indicating that marine connections were poor. After Hangenberg event, surviving Rugosa reappeared almost immediately (except in South China) and were widespread, indicating good marine connections. However, they remained poorly diversified, sometimes until the late Tournaisian. The two major extinctions (end-Frasnian and end-Famennian) and the Strunian ones were responsible for the major taxonomic differences between pre-Famennian and post-Famennian Rugosa.</ABSTRACT>

16699 <TITLE>A rugose coral biozonation for the Dinantian of Belgium as a basis for a coral biozonation of the Dinantian of Eurasia.</TITLE>
16700 <SOURCE>Tenth International Congress of Carboniferous Stratigraphy and Geology, Comptes Rendus 4: 29-31.</SOURCE>
16701 <ABSTRACT>Rugose Corals are fairly common in the Strunian to Uppermost Viséan deposits of Belgium and neighbouring areas. They complement the stratigraphic informations yielded by Foraminifera and Conodonts. A Rugose Coral biozonation of the Dinantian of Belgium including 8 zones is proposed here. This biozonation is based on taxonomic assemblages, which can be translated into morphological assemblages. These morphological assemblages are used for the creation of several morphozones, which can be traced not only throughout western Europe but also in other Eurasian areas. 16739 <SOURCE>Annales de la Societe geologique du Nord 06 (2eme serie):
97-104.</SOURCE>
16740 <ABSTRACT>Foraminifera, stromatoporoids, tabulate and rugose corals,
brachiopods, ostracodes, conodonts, and vertebrate microremains have
been investigated in two sections of the Strunian in the "Calcaire d
"Etroeungt" section (Avesnois, North of France) and the
Etaoucun section (Guilin of Guangxi, South China). Except for the
foraminifera which allow good correlations, the other benthic fossil
groups present very few taxa in common between the two sections. This
supports the endemism of the South China Strunian faunas, already
underlined by some authors.</ABSTRACT>

atrypid brachiopods from Europe and South China.</TITLE>
16752 <SOURCE>Journal of paleontology 70, 4: 588-602.</SOURCE>
16753 <ABSTRACT>These two genera are typical Devonian reef dwellers, one
genus found cementing to the undersides of corals, the other as
inter-coral forms with large pedicles. Davidsonia typically occurs
underneath platy alveolitids, demonstrating that these coral taxa were
elevated from the substrate (like platy modern Acropora hyacinthus),
contrary to general illustrations, which show them resting or cemented
to the substrate. The Davidsoniina (suborder: Devonian, but as old as
late Silurian, Pridoli) are nearly always reefal or peri-reefal in
their distribution.</ABSTRACT>

16778 <SOURCE>Geobios 24, 2: 141-155.</SOURCE>
16779 <ABSTRACT>Dendropora explicita Michelin 1846 has only been known until now, in the Boulonnais, by the two small specimens from the Michelin 's collection discovered and described by Lafuste (1981). Eighty-two new specimens have been picked out recently in the type stratum of the type area (Frasnian of Ferques area, bottom of the Patures Member, Beaulieu Formation). A new species Dendropora briceae nov. sp., very similar to D. explicita is particularly abundant (180 specimens) in the Givetian of the Boulonnais and is also present in the Givetian of the Avesnois (19 specimens). D. briceae differs fundamentally from the former type species D. explicita by closer calices. The study of those samples brings new information about the morphological features of the genus Dendropora (reticulate rhombic network); some structural characteristics (few distal tabulae, pores) are specified; the particular microstructure of the genus is confirmed. The stratigraphic distribution of the two species is specified. Moreover, the genus Dendropora is also recognized in the Givetian and the Frasnian of Afghanistan.</ABSTRACT>

16804 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 91, 1/4: 145-151.</SOURCE>
16805 <ABSTRACT>The genera Oligophylloides and Mariaephyllia are widely distributed in Lower to Upper Famennian strata of the cephalopod facies (Cheiloceras, Platyclymenia, Clymenia, and Wocklumeria genozones), abundant records now extend to the German Rhenish, Thuringian and Upper Franconian Mountains and to the Moroccan Anti-Atlas (Tafilalt), with additional discoveries in France (Montagne Noire) and Poland (Sudetes Mountains / Lower Silesia). New morphological features are described, including: large colonies with corallites fused by heterothecal layers; lateral talon structures for temporary attachment to possible sea-weed;

- the probable anomalous occurrence of an aseptal early ontogenetic phase with preseptal heterotheca.</ABSTRACT>

- 16817 <SOURCE>Abhandlungen und Berichte für Naturkunde 18: 103-135.</SOURCE>
- 16818 <ABSTRACT>New records of heterocorals from the wocklumeria stage are given for the German localities Oberrodinghausen (railroad cut), Hasselbach valley near Hohenlimburg, Ense, Dasberg, Effenberg, Muessenberg, and wocklum. Eight specimens of the three first mentioned sections are described: Oligophylloides pachytecus Rozkowska 1969, Oligophylloides tenuicinctus Rozkowska 1969, Oligophylloides parvulus n.sp., Mariaephyllia famenniana (Rozkowska 1969), Mariaephyllia aff. famenniana (Rozkowska 1969). The Moroccan locality Bordj Est near Erfoud yielded Oligophylloides sp. and Mariaephyllia n.sp. II from the wocklumeria stage, and Mariaephyllia n.sp. I from the Cheiloceras stage. Heterocorals mostly come from dysphotic cephalopod limestones (together with large-eyed trilobites), rarely from aphotic environments (accompanied by blind trilobites). The enlarged knowledge of distribution (within the cephalopod facies) indicates a cosmopolitic habitat during the Famennian, surely favoured by the postulated pseudoplanctonic mode of juvenile life. Concerning the Mid-European Variscan Mountains, both Oligophylloides and Mariaephyllia now are known in the Rhenohercynian zone (Holy Cross Mountains, Rhenish Mountains), and in the Saxothuringian zone (recent collections from Dzikowiec, Polish Sudetes, and from Schuebelhammer, Upper Franconia). * Intensive serial sectioning provides new morphological data, above all about ontogenetics of heterocorals (with insertions and reductions of septa). The complete 12-septal apparatus of Oligophylloides occurs already at a minimum diameter of 0.4 mm. A completely aseptal initial stage is surprising: it consists of a larval fixing talon and a hollow tube of purely tabular heterotheca. The original collection of the famous Heterocorallian study of Schindewolf (1941) was used for a revision of his fundamental error (upside down, with presumed concave tabulae) in corallite orientation.</ABSTRACT>

16881 <TITLE>Catalogue preliminaire des types et originaux de scleractiniares fossils conserves au Muséum d'Histoire Naturelle de la Ville de Genève.</TITLE>
16882 <SOURCE>FC&P 13, 2: 66-72.</SOURCE>
16883 <ABSTRACT>Les collections de cnidaires fossiles conservés au musée de Genève comprennent plus de 2000 échantillons dont 1160 dans la très riche "Collection Pictet" du XIX siècle (voir Bechon et al. 1981). La plus grande partie de ces échantillons est constituée par des scleractiniares du Mésozoïque (principalement du Crétacé inférieur). * En outre, il y a un bon nombre d'échantillons de l'Eocène des Alpes et du Bassin de Paris ainsi que du Miocène de l'Italie du Nord. Quelques coraux du Paléozoïque (surtout Dévonien de l'Allemagne et de l'Angleterre) complètent les collections. La liste suivante comprend exclusivement les types (holotypes, syntypes et types figurés) des cnidaires fossiles du musée de Genève. Ils sont tous du Mésozoïque et à l'exception de la "Collection Martin" et

- de la "Collection Salève" ils ont été exclusivement décrits dans les monographies classiques de Koby. * Les listes sont établis à partir des données fournies par Mme Danielle Decrouez, Genève. [from introductory part of the catalogue] </ABSTRACT>

- 16922 <ABSTRACT>The discovery of Archaeocyathan faunas in the Gonnese Formation (Cambrian, SW Sardinia) gives for the first time the age of its two members. In the "Dolomia rigata" Member, a scarce fauna of small sized Regular Archaeocyathan fauna of Botomian age was found in an oncolitic horizon. In the "Calcareo cerroide" Member a scarce Archaeocyathan fauna of Toyonian age (Elankian Auct.) was discovered only along the outer rim of the "Iglesiente platform". The presence of these faunas confirms the existence of a more open western basin either in an arid-hot climate, during the deposition of

- the *Dolomia rigata* Member or the supposed bahamian-like deposition in an humid tropical climate of the *Calcare cerroide* Member.

16948 <ABSTRACT>Archaeocyatha are recorded for the first time in Pyrenees mountains; they have been recently discovered in the Spanish part of Oriental Pyrenees (Gerona area, Terrades). They belong to the genera Rasetticyathus, Coscinocyathus, Porocoscinus, Protopharetra and Anthomorpha, very similar to the Sardinian Matoppa member and the Montagne Noire upper part of the Orbiel Formation (Lower Botomian). Epiphyton, Renalcis and Girvanella are associated and contribute to build reef mounds.</ABSTRACT>

17024 <TITLE>Palaeozoic corals in Austria: state of knowledge after 150 years of research.</TITLE>
17025 <SOURCE>Coral Research Bulletin 7: 73-86. [Dieter Weyer's 65th birthday commemorative volume; S. Schröder, H. Löser & K. Oekentorp (eds)]</SOURCE>
17026 <ABSTRACT>This paper gives a brief review of coral taxa from Austria cited in literature and their tectonic position within the Alpine mountain belt. The presence of corals in Palaeozoic rocks of this Alpine region is known for more than 150 years. With the exception of a single poorly preserved steinkern of an Ashgillian Streptelasmaticid, corals occur from the Lower Silurian to the Lower Permian. Ten genera and 125 taxa (81 Rugosa, 33 Tabulata and 11 Heliolitids) on species level were described for the first time from Austria. [original summary]</ABSTRACT>

17103 <SOURCE>Geological Magazine 142, 1: 1-5.</SOURCE>
17104 <ABSTRACT>We report the discovery of Aeronian (Middle Llandoverly) graptolites, and corals of probable Devonian age, in boudins hosted by greenschists, within the Southalpine Metamorphic Basement. These discoveries provide key constrains to the depositional age range of the protoliths. This remarkable occurrence of almost undeformed graptolites and compound corals in boudins within a metamorphic shear zone indicates very marked strain partitioning.</ABSTRACT>

17169 <ABSTRACT>*Scruttonia julli* (Pedder 1986) is described from shallow-water limestones of the central Carnic Alps and thus there is evidence of Upper Devonian in this region. Hence it follows a discussion concerning the stratigraphical range of the Middle / Upper Devonian reef-complex of the Kellerwand and Hohe warte area. The Chinese subgenus *Billingsastraea* (*Sichuanastraea*) He 1978 is proven to be a junior synonym of *Scruttonia Cherepnina* 1974, and is abandoned.</ABSTRACT>

17193 <TITLE>Rugose Korallenfaunen des Mittel- und Ober-Devons der zentralen Karnischen Alpen.</TITLE>
17194 <SOURCE>Jb. Geol. B.-A. 135, 1 [Schoenlaub H.P. & Daurer A. (eds): Neuergebnisse aus dem Palaeozoikum der Ost- und Suedalpen]: 233-260.</SOURCE>
17195 <ABSTRACT>A rugose coral fauna is described from thick shallow-water deposits on top of the Kellerwand - Hohe warte area (central Carnic Alps). Its stratigraphic use is discussed with respect to the Middle / Upper Devonian boundary. The systematic studies were made with special regard to diagenetic transformations in the microstructure of the coral skeleton which are subject to a special chapter. [original summary] The following taxa are described: *Dendrostella trigemme* (Quenstend 1879), *Battersbyia* sp., *Acanthophyllum concavum* (Walther 1928), *Grypophyllum* sp., *Stringophyllum* sp. A, *Alaiophyllum jarushevskyi* Gorjanov 1961, A.

- wirbelauense (Pickett 1967), *Temnophyllum* cf. *latum* Walther 1928 and *Pexiphyllum* sp. Investigation of the microstructure was especially done with *Dendrostella* and *Battersbyia* specimens. </ABSTRACT>

 17350 <TITLE>Fund eines devonischen Tabulatenkoralls *Caliapora* in
 Vulkanogeno-Sedimentgesteinen oestlich von Rudna Glava.</TITLE>
 17351 <SOURCE>Ann. Geol. Penins. Balkan. 37, 2: 59-68; Belgrade.</SOURCE>
 17352 <ABSTRACT>Schwachmetamorphosierte Vulkanogeno-Sedimentgebilde haben
 eine regionale Verbreitung im Rahmen des Karpato-Balkanischen Bogens.
 Auf diesen Schluss weisen die Resultate neuerer Forschungen in
 Jugoslawien und in Rumaenien hin, da die erwaehten Gebilde vom
 untersuchten Getaende mit Unterbrechungen in Richtung NNW bis zur Donau
 verfolgt werden koennen, wo sie im Guertel von Boljetin und dem
 Kozicafluss die Grundlage fuer die bisher bekannten Gebilde des "
 unteren Karbons" bilden. In Richtung SSO wurden analoge Gebilde im
 Rahmen der Serie von "Crgn Vrh" und der "Inovischen"
 Serie beobachtet, woraus zu schliessen ist, dass es sich auch hier um
 Devongebilde handelt, die ihre Fortsetzung in Bulgarien im Rahmen von
 Belogradzik und der Berkovantiklinale finden. Die
 vulkano-Sedimentgebilde haben unter den Bedingungen der Zeolithfazies
 ihre Metamorphose erfahren. * Ihr Alter wurde auf Grund des
 Tabulatenkoralls *Caliapora* sp. indet.- mittleres Devon bestimmt. Die
 palaeontologische Angabe ist bedeutend, da sie auf die Entstehungszeit
 herzynischer Orogenese und "initialer" basischer Magmate
 hinweist.</ABSTRACT>

17389 <SOURCE>Mitt osterr. geol. Ges. 70, 1977: 49-73.</SOURCE>
17390 <ABSTRACT>Description of Tabulata, Sclerospongia and Stromatoporoids (list p. 63) of probably Givetian age from Menorca. The fossils occur together with Rugosa and different Frasnian limestones in form of gravels and components of Framennian (?) mud flows within a flysch-sequence. The coral fauna is very similar to coral faunas of analogous sequences of the Great Kabyle, whereas the Stromatoporoid fauna shows a cosmopolitan character. The problem of the origin of the fossil-bearing !?!. gravels is unsolved.</ABSTRACT>

17440 <TITLE>Corales y estromatopôridos de Devónico Inferior de los Alpes Cárnicos.</TITLE>
17441 <SOURCE>Comunicaciones de las XXV Jornadas de la Sociedad Española de Paleontología.</SOURCE>
17442 <ABSTRACT> Aunque en el Devonico Medio los arrecifes tenían una amplia distribución (casi mundial), durante el Praguense (Devonico Inferior), los arrecifes fueron escasos. En la formación "Calizas de Hohe warte " en el Macizo de Seewarte y Hohe warte en los Alpes Cárnicos (Hubmann et al., 2003). en la frontera entre Austria e Italia esta representado uno de estos pocos arrecifes praguenses. * Se estudia la formación "Calizas de Hohe warte" en los afloramientos situados en la base del acantilado de la Seewarte. Esta formación representa al Praguense y una parte del Emsiense inferior (Hubmann et al., 2003). La secuencia empieza con calizas de crinoideos; sobre ellas se desarrollan estructuras arrecifales; especialmente en la parte superior se observan arrecifes parches bien desarrollados. Los bioconstructores son estromatopôridos, corales tabulados, corales rugosos y Fistullella undosa Shuysky, que se interpreta como un hidrozoo problemático. La facies de las "Calizas de Hohe warte" ha sido descrita por Pohler et al. (2007). A continuación, se proporciona una lista con los fósiles identificados en las laminas delgadas: * corales tabulados:

Heliolites aff. weneri Oekentorp & Brühl, 1999, Helioplasma aff. aliena Galle, 1973, Favosites styriacus Penecke, 1894, Platyauxum (Roseoporella) altechedatense (Dubatolov, 1959), Scoliopora (Protoscoliopora) puberulus (Janet in Dubatolov et al., 1968) (muy frecuente), Coenites falsus Dubatolov, 1963, Aulopora (Mastopora) sp. * corales rugosos: Fasciphyllum sp., Stauromatidium aff. marylandicum (Swartz, 1913), Cystimorpha indet. * estromatoporidos: Actinostroma? ex gr. clathratum Nicholson, 1886?, Plectostroma latens (Pocta, 1894) (muy frecuente), Schistodictyon? sp., estromatopôridos indet. * microproblematica: Fistulella undosa Shuysky, 1973 (muy frecuente), Renalcis granosus Vologdin, 1932.</ABSTRACT>

17453 <TITLE>Depositional Environments in the Devonian Limestone Succession of the Cima Ombladet (Carnic Alps, Italy).</TITLE>

17454 <SOURCE>Facies 12: 97-112.</SOURCE>

17455 <ABSTRACT>This study deals with a paleoenvironmental analysis of the shallow-water limestones in the Cima Ombladet succession (Carnic Alps, Italy), which range in age from Givetian to Frasnian. The major depositional environments are reef flat, open lagoon, semirestricted lagoon and sand cays. Their vertical and lateral variations suggest a regressive sequence. Rocks deposited within these sub-environments can be subdivided into twelve sub-units on the basis of lithological and faunal content. Rocks of the reef flat consist of an alternation of sparitic facies (detrital crinoidal facies, detrital crinoid-stromatoporoid facies, and detrital Thamnopora facies) and micritic facies (crinoidal facies, micritic Thamnopora facies). The open lagoon is characterized by Stringocephalus-Trypanopora facies, a thin-shelled brachiopod facies and a detrital brachiopod facies. The semirestricted lagoon environment includes the dark Amphipora facies and the dark ostracod-calcisphere micrite facies, which underwent reworking by means of lagoonal storms (detrital Amphipora facies). The sand cay consists of an intraclastic facies. The facies interrelationships can be explained by a general change in water energy responsible for the progradation of bioclast-intraclast sand bodies and the shift into the lagoons. This process has a modern analogue in most of the reefs inside the Great Barrier Reef, Australia. (Original Summary)</ABSTRACT>

17466 <TITLE>Mikrofazies, Stratigraphie und Palaeogeographie des Zentralkarnischen Hauptkammes zwischen Seewarte und Cellon.</TITLE>

17467 <SOURCE>Jb. Geol. B.-A. 133: 275-343. [in German, with English summary]</SOURCE>

17468 <ABSTRACT>By a combination of microfacies analysis, stratigraphical and tectonical methods, the Devonian of the central Carnic Alps between

Seewarte and Cellon was investigated in comparison with neighbouring areas. 14 profiles were taken, which were only accessible by alpinistic methods. 10 microfacies-types with 7 subtypes could be distinguished. Conodont samples and reef-fossils provided data for stratigraphical classification. Previous workers suggest that the Devonian rocks in the western Seewarte area developed in subtidal facies and in the eastern Cellon area, in forereef to pelagic facies. The central Kellerwand and Hohe warte was believed to represent an east-west orientated transition between the different facies types. The influence of the two subordinate nappes (Cellon subordinate-nappe and Kellerwand subordinate-nappe) was considered unimportant. As a result all further workers suggested a facies differentiation from the west to the east. New investigations discussed in this paper indicate that both the subordinate nappes are facies nappes: The Kellerwand nappe is developed in intertidal, back-reef or reef facies with more than 150 meters of Givetian reefs, the Cellon nappe in transition or pelagic facies. Overthrusting came from the south-southwest. After moving back the complicated tectonics (Abb. 33) there is a obvious north-south differentiation of facies. In comparison the facies change from the west to the east in the area is unimportant. Based upon facies differentiation, stratigraphy, tectonics and with analogies to neighbouring areas, a paleogeographical reconstruction for the central Carnic Alps was developed (Abb. 33-35). In spite of the difficulties encountered while sampling vertical walls and the destruction of fossils and sediment structure by diagenesis, an important gap was filled in the geology of the Carnic Alps.

 17492 <TITLE>Ablagerungsraum, Mikrofazies und Paläoökologie der Barrandeikalk-Formation (Eifelium) des Grazer Palaeozoikums.</TITLE>
 17493 <SOURCE>Jb. Geol. B.-A. 136, 2: 393-461.</SOURCE>
 17494 <ABSTRACT>The Barrandei Limestone Formation of the Palaeozoic of the Graz area (Austria) represents a highly fossiliferous sequence whose stratigraphic boundaries are not clearly identifiable at this stage. Locally the sequence may range from Upper Emsian to lower Givetian. In this paper the depositional conditions of the formation are discussed. Four types of microfacies and thirteen types of

submicrofacies have been recognized. The comparison of Wilson's types of microfacies with the Barrandei Limestone sequence suggests that this limestone was deposited in restricted, semirestricted and open platform environments and on the platform margin and foreslope. Microfacies and palaeoecological data indicate a depositional environment of very shallow water, with some biohermal and biostromal (reefal) development as well as areas of deeper water, i.e. quiet depositional conditions. Distribution patterns and growth habits, i.e. skeletal morphology and shape of colonies, especially of stromatoporoids and tabulate corals (favositids) and special composition of the faunal content (e.g. *Thamnopora*-*Amphipora* associations) indicate typical back reef biocoenoses. Also trace element concentrations support the sedimentological and palaeoecological evidence of the depositional environment. Deposition of higher energy mud facies is predominant. Also characteristic are sequences with a "muddying-upward trend" which indicates sedimentation under stormy conditions ("tempestites"). The introduction into the system of large amounts of fine grained clastic material is a cyclic event that accounts for the alternating deposition of limestones, marls and shales and for the highly variable amounts of acid-insoluble residue in the limestone sequence itself. It is suggested that the cyclicity is a function of eustatic fluctuations (transgressions and regressions) as observed from the "Rheinische Schiefergebirge". Some taxa indicate palaeobiogeographical connections with the Rhehercynian basin and the Aquitaine-Cantabrian terrane.

17507 <ABSTRACT>The Carnic Alps of Southern Austria and Northern Italy represent one of the very few localities on the Earth in which an uninterrupted fossiliferous sequence is exposed and well documented from Ordovician to Middle Triassic times. This paper describes and illustrates the Lower Paleozoic part of the mountain chain and in particular the Central Carnic Alps, where fieldwork only was possible by alpinistic methods (Kreutzer 1986, 1990). During the Devonian in the Carnic Alps an ecological reef complex occurs with all facies belts ranging from intertidal to pelagic environments following upon an Ordovician / Silurian carbonate platform with pioneer fauna. The Lower Paleozoic rocks are chronologically documented and illustrated on 46 plates. The paleogeographical implications of the tectonically complicated Carnic Alps are presented in an updated version. Important sections are shown with stratigraphical specifications.</ABSTRACT>

17584 <SOURCE>Magyar Allarmi Foeldt Int. évi. Jelent. 1971: 249-276 [in Hungarian, with German summary]</SOURCE>
17585 <ABSTRACT>Die Fauna, die in den beiden Strukturbohrungen von 1969-1970 angetroffen worden ist, hat die Revision der fruerehen Ergebnisse berechtigt. Im Kalksteim des bituminoesen Kalkstein Komplexes - dessen Maechtigkeit auf Grund der Bohrungen zwischen 40 und 70m variiert - wurden 10 Anthozoa-Arten gefunden, von denen 3 Arten den Tabulaten, 6 Arten der Pterocorallien, 1 Art den Heterocorallien angehoeren. Besonders wichtige Angerbe fuer die Stratigraphie ist die grosse Anzahl der Heterocorallia Art Hexaphyllia mirabilis (Duncan) denn dies beschraenkt das Alter des Sedimentes eindentig auf die Visee-Stufe des Unter Karbons, genauer gesagt auf die Dibunophyllum - 2 biozone des oberen Viseen. Auf Grund der stratigraphischen Reichweite der anderen Arten ist jedoch wohl moeglich, dass der ganze Komplex dem Viseen + der Basis des unteren Namur angehoert. Fuer die Richtigkeit der Altersbestimmung spricht auch des Vorhandensein der Art Gigantoproductus transdanubiana (Foeldvari).</ABSTRACT>

17675 <SOURCE>Mem. Ass. Australas. Palaeontols 8 [Jell P. A. & Pickett J. W. (eds): Fossil Cnidaria 5 (Proceedings of the Fifth International Symposium on Fossil Cnidaria including Archaeocyatha and Spongiomorphs)]: 99-107.</SOURCE>
17676 <ABSTRACT>Study of increase in a specimen of Turnacipora using serial acetate peels shows several types of increase within one corallum. All belong to the broad category of intravisceral increase but none begins with a simple basal mural pore (i.e. lateral increase). Of 4 cases of increase described 3 are variations on a basic type: 1, a basal mural pore partitioned by a structure derived from the wall, 2, a partitioned basal mural pore of mixed origin (partly angle mural pore), and 3, a basal mural pore derived from an angle mural pore (- intravisceral - poral increase). In the fourth case, the new wall stems partly from an altered tabella, partly from a pair of mural processes (- intravisceral - epitabular budding). This case may be teratological. Increase with a partitional basal mural pore and/or screen-like basal mural pore may have evolved in the Michelininae during the Tournaisian.</ABSTRACT>

17687 <TITLE>Allogenic and autogenic controls of reef mound formation: Late Carboniferous auloporid coral buildups from the Carnic Alps, Italy.

- 17688 </TITLE>
<SOURCE>N. Jb. Geol. Palaeont. Abh. 185, 1: 39-62.</SOURCE>
- 17689 <ABSTRACT>The development of small-scaled aulopodid coral mounds within the transgressive Late Carboniferous (early Kasimovian) highstand system tract of the Carnic Alps south of the Italian / Austrian border was chiefly controlled by global and regional conditions (rising sea-level and reduced terrigenous influx), rather than by autogenic biological factors. The tabulate coral *Multithecopora* did not framebuild but baffled homogenous micritic mud. This effect was enhanced by episodic slight increases of turbulence levels. Otherwise the mound sediment is the same as in background situations (calcareous siltite). This model differs from current reef mound models but may be applied to many fossil occurrences.</ABSTRACT>

17779 <SOURCE>Facies 17: 73-90.</SOURCE>
17780 <ABSTRACT>The coral patch-reef of Laisacker (Neuburg a.d. Donau, Southern Franconian Alb) exhibits three facies zones: the reef core consists of reef debris, there is almost no reef framework. The core facies, interfingering with the reef debris facies is built up by fine-grained reef detritus with intercalated coarse-grained layers of

partly high porosity (up to 24%). They mainly consist of coral fragments (up to 83%) and reach 0.80 m in thickness. These coarse-grained layers have been formed by storms. The interreef facies corresponds to massive limestones. Destruction of the reef framework was favoured by bioerosion. The high still open porosity of the coarse-grained reef rubble was caused by high freshwater flow rates delimiting cementation and favouring dissolution.</ABSTRACT>

17791 <TITLE>A Middle Permian calcisponge / algal / cement Reef: Straza near Bled, Slovenia</TITLE>
17792 <SOURCE>Facies 10: 179-256.</SOURCE>
17793 <ABSTRACT>Middle Permian reef limestones exposed at the localities of the Straza quarry, Straza Hill and Bohinjska Bela near Bled (northwestern Slovenia) have been studied with respect to microfacies and paleontological criteria. Allochthonous carbonates (limestone breccia represented by cement-rich litho/bioclastic rudstones; matrix-rich poorly sorted litho/bioclastic rud/floatstones; coarse-grained lithoclastic packstones) are present in far greater quantities than autochthonous carbonates (calcisponge boundstones and Archaeolithoporella/calcisponge boundstones with syndimentary botryoidal carbonate cements; bioclastic crinoidal packstones) in the Straza quarry. Straza Hill is characterized by fine-arenitic bioclastic grainstones with foraminifers and algae.</ABSTRACT>

17805 <SOURCE>Palaeontographica A167, 1-3: 1-9.</SOURCE>
17806 <ABSTRACT>Permosoma Jaekel 1918 consists of a chambered skeleton, the single chambers of which are connected. They have been closed externally by a movable operculum. Within the chambers there exists an inner skeleton (crypta) that seems to have consisted, originally, of organic material and that is separated from the walls of the chambers by an "intervallum". Externally it opens in canals. A similar skeleton is shown by Khmeria Mansuy 1914. The systematic position of both is unknown. [original summary; Permosoma has also been recorded by wendt (1977) from Permian strata in Tunisia and assigned to the tabulate corals]</ABSTRACT>

17817 <TITLE>Upper Permian Richthofeniid Buildups of Chios Island (Aegean Sea) - Preliminary Report.</TITLE>
17818 <SOURCE>Jb. Geol. B.-Anst. 139, 1: 21-28.</SOURCE>
17819 <ABSTRACT>Gymnodiacean limestones of lower Upper Permian age from the northern part of the island of Chios (Greece) include mass occurrences of richthofeniid brachiopods. Paleobiological and ecological data indicate a calm water environment for these reefs. Field observations as well as conclusions from the investigation of thin sections provide new evidence for the mode of life of richthofeniids. In contrast to previous functional models favouring richthofeniids as encrustors or mudstickers, they are recliners according to our interpretation.</ABSTRACT>

17830 <TITLE>A Richthofeniid-Microbial-Sponge Buildup in the Upper Permian of Chios (Greece).</TITLE>
17831 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
17832 <ABSTRACT>The "Gymnodiacean Limestone" in the Upper Permian of Chios contains in its lower part abundant Richthofeniids. They are concentrated in the basal part of a reef-like buildup which is constructed in its upper part mainly by sponges and abundant microbial structures. The reef is interpreted as a shallow water buildup grown under low energy conditions. Our observations suggest that the Richthofeniids of Chios lived as recliners acting as substrate stabilizers and bafflers.</ABSTRACT>

17870 <SOURCE>Razprave IV razr. SAZU 32: 175-213.</SOURCE>
17871 <ABSTRACT>Above Julian-Tuvalian bedded limestone the cephalopod limestone of Hallstatt facies (anatropites domain) follows which passes conformingly into bedded Dachstein limestone. It is overlain by Dachstein reef limestone, which is, on Razor and Planja, built of corals, sponges and spongostromate encrusting formations as primary reef builders. Pelecypods, snails, brachiopods and crinoids are reef dwellers remaining in nests. Seven species of corals (among them three new: Protoheterastraea razorensis, Cyclophyllia raricorallita, Margarosmia nova) are described systematically. The bedded and reef Dachstein limestones are ranged to the Lower Norian (Latian).</ABSTRACT>

17883 <SOURCE>Abhandlungen der Geologischen Bundesanstalt 50: 477-507.</SOURCE>
17884 <ABSTRACT>From the Pantokrator limestone of the island Hydra, Greece, 24 species of corals belonging to 14 genera are described. Two genera and seven species are new. The corals confirm a Carnian to Lowermost Norian age of the studied localities. The found corals can be compared to south European localities like Italy, Slovenia, south Hungary, Romania and Turkey, and seem to predominate in southern shallows of the Tethys. Nevertheless, almost one third of the new species indicate special and somewhat different environments in Hydra during the Carnian period.</ABSTRACT>

17935 <SOURCE>Facies 34, 1: 77-82.</SOURCE>
17936 <ABSTRACT>Upper Triassic to Lower Jurassic shallow-water carbonate sequences of the 'Pantokrator limestones' are widely distributed in the Argolis Peninsula, southern Greece. Within this sequence are some reef or reefal structures. In the Mavrovouni Mountains, near Sarameika, 6km SE of the ancient theatre of Epidavros (Argolis Peninsula), a Norian-Rhaetian reef complex has been identified. This is the first well-documented Norian-Rhaetian reef in Greece. The main reef builders are coralline sponges (' sphinctozoans,' ' inozoans', and sclerosponges), followed by dendroid, cerioid, and solitary corals, and algae. The reef type corresponds to a 'sponge-coral reef.</ABSTRACT>

17975 <ABSTRACT>The new "coralline"; sponge Chaetosclera klipsteini n.gen. n.sp. from the Early Carnian Cassian Beds (Dolomites, Italy) is described. The chaetetid basal skeleton is composed of aragonitic spherulites. The spicular skeleton consists of long styles which are arranged in groups of 3 to 4 inside of the skeleton walls or along the internal sides of the tubes. The scleres and the sclere arrangement indicates a halichondriid demosponge. It is the first record of a halichondriid demosponge with a basal skeleton from the Triassic.</ABSTRACT>

- Upper Triassic of the northeastern Dolomites (Italy).</TITLE>
17987 <SOURCE>Journal of Paleontology 69, 3: 416-431.</SOURCE>
17988 <ABSTRACT>The calcareous skeletons of 17 species of Triassic demosponges from the northeastern Dolomites have been analyzed for microstructure and diagenesis. The four microstructures recognized (irregular, spherulitic, penicillate aragonitic, and homogeneous granular Mg calcite) are described in terms of mineralogy; shape, dimension, and arrangement of microstructural elements; mode of growth; and possible biomineralization. The diagenesis in these sponge carbonate skeletons is of an aggrading type that occurred in diagenetic units, semi-closed systems, delineated by organic phragmas, which controlled the flux of diagenetic fluids. We tentatively interpret these phragmas as the remains of water-insoluble macromolecules for space delineation during the biomineralization process. In the aragonitic skeletons the preservation grade is correlated with Sr content, and the replacement of aragonite by calcite is marked by a Sr value around 4,000 p.p.m. Calcitized aragonite still retains a detectable amount of Sr. In Mg calcite skeletons the continuous and regular increase of grain size is inversely correlated with Mg content and directly with the distance from the organic phragmas.</ABSTRACT>

18000 <SOURCE>Geol.-Palaeont. Mitt. Innsbruck 18 131-150.</SOURCE>
18001 <ABSTRACT>In the southalpine Triassic of the central Karawanken Mountains (Carinthia, Austria) Late Anisian reef limestones at places are sharply overlain by a thin sequence of red pelagic limestones. These pelagic limestones are dated as Early Fasnian (Xenoprotrachyceras reitzi zone; Spongosilicarmiger italicus zone; Paragondolella trammeri praetrammeri zone) based on conodonts and radiolarians. The siliceous sponges from the red nodular limestone (Weisse Wand Member) of Early Fasnian age represent an autochthonous soft-ground fauna of an aphotic pelagic environment. Demospongiae are represented by 42 types of spicules, three of them being new. They constitute only about 30% of the total fauna, the rest is comprised by the Hexactinellida. Calcisponges are lacking. The Hexactinellida are represented by 55 types of spicules, 11 of them are new. Three of them, monospecific genera, belonging to the Amphidiscophora, Hexactinosa and *Lyssakinosa*; are described. Of importance is the first appearance of the genus *Farrea* (Clavulari), which till now could only be traced back to the Late Cretaceous and now must be taken back to the Fasnian. The same is true for the genus *Eurete*, whose oldest species have been reported from the Late Cretaceous till now. Finally the stratigraphic significance of the siliceous sponges is discussed to point out that distinct differences exist between siliceous sponges of the Early and Late Fasnian, although they are all derived from the same environment.</ABSTRACT>

- 18066 <ABSTRACT>Carnian small scleractinian coral fauna found in the Malé Karpaty Mts (Western Carpathians), is closely related to early late Carnian corals of the Dolomites (Southern Alps). The former fauna includes three new genera: Carpathiphyllia (type species: C. regularis n.sp.), Pontebbastraea (type-species: Stylophyllopsis pontebbaeae Volz), Protostylophyllum (type-species: Stylophyllum praenuntians Volz), and a new species of Volzeia (V. carpathica n.sp.). The Carnian age of the upper part of the Veterlin platform sequence proves the continuous development of Triassic carbonate platform, which was never interrupted by the Lunz/Rheingraben clastic interval (unlike to the Choc-and/or Lunz Nappe sequences).</ABSTRACT>

- 18079 <ABSTRACT>This is the first report concerning an Early Norian coral fauna from the Northern Calcareous Alps. The coral-bearing limestones outcrop in the vicinity of the Feisterscharte, in the southern Dachsteinplateau. In this Alpine region, aside from the Dachsteinplateau, Early Norian corals have been recorded only from the Gosaukamm range, which is also a part of the Dachstein massif. The exposures at Feisterscharte show one of the most taxonomically diversified Early Norian coral assemblages known so far. In the assemblage, Carnian genera are prevailing in number, and Early Norian index species, Pachysolenia cylindrica Cuif and Pachydendron microthallos Cuif are frequent. The Early Norian age is proved by conodonts. Some remarks on microfacies and foraminifera content of the

reef and associated limestones are given. The rocks represent the initial growth stage of the Norian to Rhaetian Dachstein carbonate platform.</ABSTRACT>

- 18157 <ABSTRACT>The paper presents the distribution and taxonomy of the Rhaetian coral fauna in the Tatric, Fatric, Hronic and Silicic paleogeographical zones of the Western Carpathians. The taxonomic spectrum of the corals from the Fatric zone is the most typical of the Carpathians, and resembles that of the Alps in the abundance of reimaniphylliid corals and frequent phaceloid growth forms, but it differs from the Alpine spectrum in its lower generic diversity. The assemblage from the northernmost zone, formed by the Tatric Superunit, is closest to the Early Jurassic fauna from the British Isles. Two new species are described: Zardinophyllum carpathicum sp.n. and Stylophyllopsis bobrovensis sp.n.</ABSTRACT>

- 18170 <ABSTRACT>A research through optical and electron scanning microscope has been developed on more than 120 specimens of an Alpine Triassic single or phaceloid coral, here still named Protoheterastraea leonhardi (Volz) (pars). The specimens are still preserved in their original mineralogical composition (aragonite, with high strontium content) and structure. * Bilateral symmetry of septal insertion, peripheral insertion of septa two-by-two, absolute predominance of protosepta, non cyclic insertion of metasepta, are all characters more reliable to the

Late Paleozoic Rugosa than to the Scleractinia. On the other hand, no pinnate septal insertion occurs, as in Rugosa, and a theca is constantly present as an essential element of the skeleton. * Theca is given by aragonitic fibrolamellae, longitudinally finely folded. Contiguous, terminal surfaces of c-axes of aragonitic aggregates of contiguous fibrolamellae [are] knit together and give origin to a typical fibrous tissue. * Septa - discontinuous, frequently spiny and inwardly inclined - seem to have a fibrolamellar microstructure too: they seem to arise from a progressive infolding of thecal fibrolamellae. This structure cannot be relied either to the Rugosa or to the Scleractinia. * Further investigations are in course on the peculiar structure of *Protoheterastraea leonhardi* (Volz) (pars).

18220 <TITLE>A model for furcate septal increase in a Triassic scleractiniamorph.</TITLE>
18221 <SOURCE>Acta Palaeontologica Polonica 49, 4: 529-542.</SOURCE>
18222 <ABSTRACT>Triassic corals with septa that branch repeatedly and centripetally are here assigned to a new genus Furcophyllia. Septa of *F. septafindens* (Volz, 1896), re-described from the Italian Dolomites, are composed of 3-10 blades ("septal brooms"). Distances between adjacent septa and their branches are equal, and the thickness of all blades is approximately the same throughout ontogeny. However, none of the septal brooms show the same branching pattern. Proposed herein is a simple computer model that reproduces septal pattern, similar to that of *Furcophyllia*, based on a minimal set of rules: (i) uniform coverage of intra-calicular space; (ii) regular bifurcations following some probability; (iii) keeping some minimal distance between septal branches. The elaborate septal pattern of *Furcophyllia* suggests a distinct organization of the polyp's soft tissue, especially mesenteries whose appearance in modern corals is associated with insertion of sclerosepta. Hypothesis 1 suggests that mesenterial pairs flanked only "septal brooms" and that septal branches functionally corresponded with septal microarchitecture. Hypothesis 2 suggests that mesenterial pairs developed between all septal branches that functionally correspond with conventional septa. Delicate menianae, which developed on *Furcophyllia* septal faces (and many other Triassic corals) resemble similar septal microarchitecture of the Recent agariciid *Leptoseria fragilis* and may be closely related to the suspension feeding strategy of this coral. The furcate septal arrangement in *Furcophyllia* is unique among Triassic corals, and generally, among Mesozoic and Cenozoic corals. The only analogous corals are Cretaceous *Aulastraeoporids* (e.g., *Preverastrea*, *Paronastraea*), *Trochoidomeandra*, and some Jurassic rhipidogyrids having secondary (apophysal) septal branches. In some Recent caryophylliids (*Trochocyathus rhombocolumna*, *Phacelocyathus flos*) primary septa may also split dichotomously and centripetally.</ABSTRACT>

18260 <SOURCE>Geobios 20, 5: 571-589.</SOURCE>
18261 <ABSTRACT>A new species of a coralline sponge, Cassianothalamia zardinii n.gen. n.sp., from the Lower Carnian Cassian Beds (northern Italy) is described. The new species possesses a secondary thalamid basal skeleton with a spongocoel and the internal structure is constructed of horizontal elements (trabecula) and vesiculae. The microstructure of the basal skeleton is composed of an irregular high Mg-calcite. From the spicular skeleton aster-microscleres can be preserved. In rare cases, monaxonid megascleres can also be found. Therefore the new sponge is probably a representative of the demospongid order Hadromerida.</ABSTRACT>

18299 <SOURCE>Berliner geowissenschaftliche Abhandlungen E09: 253-281.</SOURCE>
18300 <ABSTRACT>Palaeobiological models of four selected species of sphinctozoan coralline sponges from the Cassian Beds (Lower Carnian, Dolomites) have been established using, among others, luminescence technique. The latter has been successfully used to estimate the organic content and diagenetic history of skeletons. Recent investigations yield the differentiation of three steps in the secretion of the skeleton in coralline sponges, according to which skeletal elements can be classified. The identification of these elements renders information on the way of secretion of the basal skeleton, the relative position of the soft tissue, and the function of skeleton. Two basic types of sphinctozoan organisation can be distinguished: a matrix type, where a rigid framework, secreted in an organo-spicular matrix penetrates the soft tissue (as in stromatoporoid coralline sponges) and a cortex type, where the skeleton is secreted by a specialized subdermal layer (cortex) surrounding the sponge body. These organizational types bear no phylogenetic implication.</ABSTRACT>

- 18365 <ABSTRACT>The scientific contribution of Aleksandr Ivanovich is considerable. He made important changes to the Ordovician, Silurian, and Devonian stratigraphy of Central Tadjikistan. His stratigraphic schemes were widely accepted and used in the course of geological mapping. He demonstrated the large diversity of Upper Ordovician, Silurian, and Lower Devonian Rugosa in Central Asia. He established 22 new genera, most of which are widely accepted. In addition he identified about 100 Rugosa species that were previously unknown in Central Asia. 60 papers were published based on these studies. [excerpts from biographical note on A.I. 18376 <TITLE>Zur Sphinctozoen-Fauna der obertriadischen Riffkalke (" Pantokratorkalke") von Hydra, Griechenland.</TITLE>
18377 <SOURCE>Geologica et Palaeontologica 17: 179-205.</SOURCE>
18378 <ABSTRACT>The Sphinctozoa (segmented calcareous sponges) belong to the most important framebuilding organisms of the Pantokrator reef limestone on Hydra. At least 13 genera and more than 27 species occur, three of them are new: Amblysiphonella minima n.sp., Cryptocoelia lata n.sp. and Zardinia cylindrica n.sp. This fauna corresponds more to the Ladinian and Carnian faunas of the N-Tethys (Ladinian Wetterstein limestones of the Alps and the Carpathians; Carnian limestones of Slovenia, Murztal Alps and Cassian beds) than to those of Norian or Rhaetian age (Dachstein reefs in the Alps and in Sicily). The Pantokrator reef limestones of Hydra are mainly of Carnian age.

18390 <SOURCE>N. Jb. Geol. Palaeont. Abh. 150, 1: 111-125.</SOURCE>
18391 <ABSTRACT>Stromatoporooids did have an aragonitic skeleton, as can be demonstrated by material from the Cassian beds (Cordevolian, Southern Alps) that has suffered hardly any diagenetic alteration. Since their skeletal architecture and microstructure (irregular, clinogonal and orthogonal arrangements of aragonite needles) exhibits close similarities to certain calcareous sponges, they are regarded as a conservative order of the Calcispongiae closely related to Pharetronida.

18506 <TITLE>Localization of minor elements by EOS microanalysis in aragonitic sponges from Cassian beds, Italian dolomites.</TITLE>
18507 <SOURCE>Lethaia 17, 2: 133-138.</SOURCE>
18508 <ABSTRACT>The minor elements Sr, S, K, Mg, Fe, and Mn were detected by electron microprobe EDS (electron dispersive spectrometer) in small regions of the skeletal tissue of the Triassic sponges Sestrostomella robusta (Zittel), Hartmanina involuta (Klipstein), Atrochetetes medius Cuif & Fischer, Ceratoporella sp., and Eudea polymorpha (Klipstein) from Alpe di Specie (St. Cassian Beds, Dolomites, Italy). Data were compared with analyses of the modern sponges Astrosclera willeyana Lister from the Mozambique Channel and Ceratoporella nicholsoni (Hickson) from the Bahamas. Sr content in Triassic sponges (mean value 9,300 ± 600 ppm) is similar to the Sr content of Recent samples (mean value 8,500 ± 1,500 ppm). This concentration of Sr shows very slight biochemical fractionation like oolitic aragonite. It is therefore possible to infer that the Triassic sea of the St. Cassian Beds had the same Sr/Ca ratio and equal aragonitic depositional conditions as those presently found in the Bahamas and the Channel of Mozambique, i.e. warm shallow waters. Generally, we did not observe a preferential distribution of minor elements with respect to structure. Only when a lower concentration in the center of spherules is observed does a preferential distribution pattern seem to exist. This could mean an

initial stage of Sr leaking indicative of an incipient diagenetic process (excluding experimental errors or morphological effects). Excluding these exceptions, the Alpe di Specie spongal fauna is surely diagenetically unaltered. The Sr content shows that the micritic microstructure of Eudea polymorpha is not due to a diagenetic process either. The constant, clearly detectable occurrence of sulphur (mean value 1,000 ppm) was observed. In addition, the S content was found to be linearly correlated with the strontium content. Sulphur is probably of primary organic origin. [original abstract]

 18533 <SOURCE>Bolletino della Societa Paleontologica Italiana 13, 1-2: 99-107.</SOURCE>
 18534 <ABSTRACT>Preliminary report on the microstructure of some aragonitic Upper Triassic Sponges. The microstructure of 8 species of calcisponges (Inozoina) found in St. Cassian strata (Dolomites region, Italy), has been studied. * Histologic study and mineralogic analyses show that the calcareous skeleton is entirely built by aragonite. * Three chief types of microstructure have been recognized: spherulitic, in which the aragonite crystals radiate out from a central point; penicillate, in which the aragonite crystals fan out from centers in **"water jet"** structures; micritic appearance, characterized by an aggregate of microcrystals isooriented. * A comparison with recent calcareous sponges is given. The skeletons of examined species bear a certain striking resemblances to that of Murrayonidae and particularly of Sclerospongiae.</ABSTRACT>

18559 <SOURCE>Acta Palaeontologica Romaniae 6: 375-384.</SOURCE>
18560 <ABSTRACT>The study is an approach of the Jurassic and Triassic deposits in Dealul Melcilor (Brasov), from the paleontological point of view. Specimens were collected during two field trips in 2005 and 2006. It is the first study dealing with the fauna there in the last 30 years, and after great landscape transformations. New organisms for the area are also mentioned within the fauna. A special attention is regarded to the Poriferans. A brief comparison with the St. Cassian type associations was made. 18676 <SOURCE>Facies 06: 203-296.</SOURCE>
18677 <ABSTRACT>The Gosaukamm may be regarded as an example of a continuous synsedimentary degradation of shelf margin areas with isolated reefs. More than 70% of the Dachstein limestone samples studied are bioclastic and lithoclastic rudstones and bioclastic grain/packstones composed of reworked and encrusted reef biota. Low-growing frame-building organisms (predominantly calcisponges) were responsible for the formation of primarily non-rigid frameworks situated at the margin or on protected parts of the foreslope. Stabilization of the reef framework was possible due to the very strong biogenous encrustation (mainly by algal crusts) and by a rapid submarine cementation. Destruction of the marginal reefs by hurricanes and mass flows was influenced by eustatic changes of sea level. Therefore, no clear distinction can be made with regard to various parts of a reef-complex; (back-reef, central reef area, fore-reef) even though the bulk of the sediment can be compared with fore-reef breccia;. 18689 <SOURCE>SEPM Special Publications 30 [D.F. Toomey (ed.): European Fossil Reef Models]: 291-359.</SOURCE>
- 18690 <ABSTRACT>In the Northern Calcareous Alps of Austria and Bavaria, Upper Triassic reefs are known from the Carnian (parts of the Wetterstein Reefs; Tisovec Limestones), and from the Norian and Rhaetian (Dachstein Reef Limestones; "upper Rhaetian" reef limestones; Kossen coral limestones). The Dachstein reefs developed predominantly on the southern exposed platform edges. The upper Rhaetian Reefs were formed upon shoals within the relatively shallow Kossen Basin (Roetelwand, Feichtenstein, Gruberalm), near the inner boundary of the Dachstein Platform (Steinplatte), or upon the Dachstein Platform (Adnet). 18714 <TITLE>A Down-slope Upper Triassic Reef Mound: Aflenzer Limestone, Hochschwab Mountains, Northern Calcareous Alps.</TITLE>
18715 <SOURCE>Facies 16: 23-36.</SOURCE>
18716 <ABSTRACT>A small reef mound occurring within the well-bedded, chert-bearing Norian Aflenzer Limestones of the Aflenzer Buergeralm (south eastern Hochschwab Mountains, Styria, Austria) is described with respect to microfacies and paleontological criteria. The mound was formed in a down-slope position near the transition between basinal sediments (Aflenzer Limestone, exhibiting a shallowing-upwards sequence) and marginal platform carbonates (Dachstein Limestone). The transitional zone is characterized by a change from open-marine pelagic carbonates with allochthonous intercalations at the base to protected platform environments as well as shallow-marine platform slope deposits near the top. The biota of the reef mound (corals, calcisponges, hydrozoans, calcareous algae, foraminifera, microproblematica) correspond with those of Dachsteinkalk reefs. Three communities can be distinguished according to dominant corals and calcisponges (Thecosmilia-Paradenigeria community, Astraeomorpha community, Paravesicocaulis community). The microfacies of the massive, partly dolomitized and stylolitized reef limestone is characterized by a bioclastic floatstone at the base of the mound, overlain by sponge bafflestone, coral-bafflestone, spongiostromate bindstone, coral-sponge framestone, and sponge-hydrozoan bafflestone, without regular distributional patterns. The bedded limestones below the reef

carbonates consist of bioclastic lime mudstones with radiolarians; the overlying bedded limestones are composed of peloidal and bioclastic grainstones and packstones as well as rudstones indicating a termination of the reef growth by a rapid allochthonous sedimentation perhaps caused by slumping or storm effects.</ABSTRACT>

18727 <TITLE>Paleoecology of Upper Triassic Reefs in the Northern Calcareous Alps: Reef Communities.</TITLE>

18728 <SOURCE>Facies 16: 157-186.</SOURCE>

18729 <ABSTRACT>The community is the standard unit of analysis in ecology because through it both physical and biological aspects of the ecosystem can be determined. It offers the same potential in paleoecology. The communities of the upper Triassic reefs are analyzed from the literature and our own field work in order to determine their characteristics and to assess their usefulness. Six communities are recognized on the basis of R-mode cluster analysis of the dominant frame-builders in Roetelwand reef and from descriptions and our observations in other reefs. The Thecosmilia or High-growing coral, the Hydrozoan-tabulozoan and the Sponge communities are most widespread. The High-growing Astraeomorpha, Low-growing coral and Solenopora communities are less common. Each community is characterized by a few dominant taxa and a larger number of associated taxa. The fidelity of the dominant taxa to their community is generally high; the fidelity of many of the associated taxa are typically lower and these taxa occur in a number of communities. Consequently, there is considerable overlap in composition between stands of different communities. In addition, the communities typically occur in patches only a few meters in diameter, and particularly in the Hydrozoan-tabulozoan community, the composition may differ considerably between adjacent patches.</ABSTRACT>

18767 <SOURCE>Razprave IV. razreda SAZU 30, 3: 75-127.</SOURCE>
18768 <ABSTRACT>Continuous reef sedimentation throughout Carnian was established. On the basis of position and fossil assemblages the reef complex was subdivided into Cordevolian, Julian, and Tuvanian. Studied were 23 species of reef fossils which comprise corals, chaetetids, stromatoporoids, solenoporoids and microproblematica. Among them appear two new genera and three species of corals and one of chaetetids. In the paleoecological aspect the reef complex represents shallow marine deposition on the Julian carbonate platform. Laterally it passes into deeper marine deposits of intraplatform channels which are connected to the Slovenian basin. [original summary] The new taxa are: Protoheterastraea minor n.sp., Pokljukosmia tuvalica n.gen. et n.sp., Rhoalodendron juliensis n. gen et n.sp., Atrochaetetes cylindrica n.gen. et n.sp.</ABSTRACT>

- 18807 <ABSTRACT>The development of peculiar margin facies and abundant talus breccias within the Dolomia Principale inner platform is commonly observed in the Lombardy Basin during the Norian. The organisms building these margins are mainly serpulids, benthic microbes, subordinate porostromata and other encrusting forms; typical margin organisms, as sponges or corals, are extremely rare or absent. The buildups form narrow rims along the borders of tectonic-controlled intraplatform basins. Regional back-stepping and progradation of the margin facies on the talus breccias produced by the erosion of the reef is commonly observed in the uppermost Dolomia Principals depositional system widespread occurrence of serpulids and microbial margins in middle-late Norian times is indicative of stressed environmental conditions - fluctuation of salinity and temperature on the inner platform and in the intraplatform basins - controlled by palaeogeographic setting. Physical characteristics allowed the bloom of forms able to develop in a wide range of environmental conditions, such as serpulids. In the Late Norian, major input of fine-grained elastics is recorded; close to the Norian-Rhaetian boundary, carbonate ramps were regionally restored. Locally, small serpulid and microbial bioconstructions still persist in the lowermost part of the shaly succession, even if they are less abundant with respect to the Dolomia Principale. Patch-reefs generally do not build a platform margin, but represent isolated mounds within shaly deposits. These build-ups occur on the edge of former structural highs; the communities survived the environmental change responsible for the siliciclastic input and locally managed to produce mounds during the deposition of the lower part of the upper depositional system (Riva di Solto shale).</ABSTRACT>

18858 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. &; Gunke F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
18859 <ABSTRACT>The sedimentation of the North-Alpine Middle and early Upper Triassic ("wetterstein Reefs";) passed through three stages, a homoclinal ramp in the late Anisian, a distally steepened ramp in the Fassanian, and a rimmed platform in the Longobardian and early Julian. This evolution from homoclinal ramp to rimmed platform was a continuous, dynamic process, creating a morphologically accentuated reef-basin topography. It is partly controlled by biota and by accommodation changes, which were due to sealevel fluctuations and tensional tectonics. In contrast to earlier assumptions, the start of the first North-Alpine reefs after the crisis at the Permian / Triassic boundary was caused by a basin-wide or global sealevel rise in the late Anisian to early Ladinian.</ABSTRACT>

18870 <TITLE>Response of Triassic Reef Coral Communities to Sea-level Fluctuations, Storms and Sedimentation: Evidence from a Spectacular Outcrop (Adnet, Austria).</TITLE>
18871 <SOURCE>Facies 40, 1: 229-280.</SOURCE>
18872 <ABSTRACT>The Upper Rhaetian coral limestone of Adnet, southeast of Salzburg, Austria has been repeatedly referred to as one of the most spectacular examples of an ancient 'autochthonous' coral reef structure. The 'Tropfbruch' quarry is probably the best outcrop for interpreting the distributional patterns of biotic successions and communities of a late Triassic patch reef. Our study is based on the interpretation of a) outcrop photographs, b) reef maps resulting from quadrat transects, and c) the analysis of quantitative data describing the distribution and frequency of reef organisms and sediment. A new methodological approach (combination of reef mapping and photo-transects) is used to obtain quantitative field data which can be compared in greater detail with data from modern coral reefs investigated by corresponding quantitative surveys. 18883 <TITLE>The Ladinian-Carnian Reef Facies of Monte Caramolo (Calabria, Southern Italy).</TITLE>
18884 <SOURCE>Facies 30: 101-118.</SOURCE>
18885 <ABSTRACT>In the Triassic of the San Donato Unit (Calabrian Apennines, Italy) a perireefal facies association of limestones and dolomites, hosting a Ladinian - (?Carnian) fauna, has been recognized. This facies association is flanked by black, ostracode-bearing, calcareous marbles and evolves to peritidal dolomites, Carnian and possibly Norian in age, characterized by strong synsedimentary tectonics. The San Donato Unit has been strongly affected by alpine tectonics, resulting in pervasive deformation and metamorphic recrystallization (greenschist facies); nevertheless, careful observation on selected outcrops enabled the distinction of the following main facies: - Sponges-biogenetic crust-cement boundstone; - Reef debris rudstone; - Dasycladacean packstone-grainstone. 18896 <TITLE>Sedimentology of the Upper Triassic Reef Complex at the

Hochkonig Massif (Northern Calcareous Alps, Austria).</TITLE>

18897 <SOURCE>Facies 30: 119-150.</SOURCE>

18898 <ABSTRACT>The Upper Triassic Dachsteinkalk of the Hochkonig Massif, situated 50 km south of Salzburg in the Northern Calcareous Alps, corresponds to a platform margin reef complex of exceptional thickness. The platform interior limestones form equally thick sequences of the well known cyclic Lofer facies. Sedimentation in the reef complex was not so strongly controlled by low-amplitude sea-level oscillations as was the Lofer facies. The westernmost of the 8 facies of the reef complex is an oncolite-dominated lagoon, in which wave-resistant stromatolite mounds with a relief of a few metres were periodically developed. The transition to the central reef area is accomplished across the back-reef facies. In the back-reef facies patch reefs and calcisponges appear. The proportion of coarse bioclastic sediment increases rapidly over a few hundred metres before the central reef area is encountered. The central reef area consists of relatively widely spaced small patched reefs that did not develop wave-resistant reef framework structures. The bulk of the sediment in the central reef area is coarse bioclastic material, provided by the dense growth of reef organisms and the wave-induced disintegration of patch reefs. Collapse of the reef margin is recorded by the supply of large blocks of patch material to the upper reef slope. Additionally, coarse, loose bioclastic debris was supplied to the upper reef slope and this was incorporated into debris flows on the reef slope and turbidites found at the base of the slope and in the off-reef facies. Partially lithified packstones and wackestones of the middle reef slope were modified by mass movement to form breccia and rudstone sheets. The latter reach out hundreds of metres into the off-reef facies environment. A reef profile is presented which was derived by the restoration of strike and dip formation. In conjunction with constraints imposed by sedimentary facies related to slope processes, the angle of slope in the reef margin area ranged from 11 to 5, forming a concave (dished downwards) slope. Water depth estimations require that the central reef area did not develop in water less than 10 metres depth. At the reef margin water depths were about 30 metres, at the base of the reef slope 200 metres and deepening in the off-reef facies to 250 metres. While previous work on reef complexes from this type of setting suggests growth on heavily storm-dominated environment, the present author finds little evidence for storm-influenced sedimentation and reworking in the central reef area. Post-depositional processes were characterized by continued slope processes causing brecciation and hydraulic injection of red internal sediments downwards into the reef slope and off-reef limestones. Hydrothermal circulation caused a number of phases of post-depositional (diagenetic) brecciation. There appears not to have been an important period of emergence at the Triassic/Jurassic boundary.</ABSTRACT>

18910 <SOURCE>Journal??? volume??? pp 99-115. [in Hungarian, with French summary]</SOURCE>

18911 <ABSTRACT>Sur le terrain des villages de Aggtelek et de Josvafo en Hongrie du Nord, se situe une formation récifale s'étendant sur plusieurs km² sur la surface. Elle est part du terme Anisien de la

série des calcaires de Wetterstein du Trias moyen. 3 aires principales à faciès différents peuvent être distinguées à l'intérieur de la masse récifale incluse dans des sédiments à Dasycladacées, déposés dans les eaux peu profondes ce sont : 1 - récif central caractérisé par une paléobiocénose de polypiers, hydrozoaires et éponges calcaires ; 2 - un talus périrécifal de type "fore-reef", situé du côté où la mer se fait et caractérisé par une paléobiocénose de brachiopodes, mollusques et échinodermes ; 3 - derrière le récif central, du côté sous le vent il y a une zone à débris de type "back-reef" avec une paléobiocénose d'échinodermes et mollusques. * Le complexe récifal d'une épaisseur de 500 à 600m commença à grandir au début du Pelsonien et fut supprimé déjà au cours de l'Illyrien supérieur c'est-à-dire avant même le dépôt des sédiments de l'horizon à *Diplopora annulatissima* Pia. A l'Illyrien supérieur, tout le territoire étudié était couvert en continuité par des sédiments à Dasycladacées.

19002 <ABSTRACT>Numerous small patch-reefs are found on the top of the Kossen beds in the Northern Calcareous Alps which are generally called Upper Rhaetian reefs (Fabricius 1966: 20, Tollmann 1976: 258). * Several of these patch-reefs are situated in the Salzburg region (Osterhorngruppe). Four of them, adjacent to each other, have been investigated in two thesis undertaken in the Paleontological Institut

of the Erlangen-Nuernberg university. P. Schaefer (1979) has studied the Roetelwand reef and Adnet reef near Hallein. * The present dissertation deals with the Feichtenstein reef and the Gruber reef (Austrian topographical map 1:25000, sheet Hintersee 94/2). * The studies are focused on the paleontological investigation of the reef-building organisms. A general list of the fauna and flora is given.

19093 <ABSTRACT>In the Lower Carnian times on the territory of the Northern Julian Alps a shallow carbonate platform extended on which non-bedded "Diplopora" limestones were deposited with coral-sponge patch reefs in between. The reef fauna was investigated in detail, the fossil communities were established and the main facies types of rocks were described.</ABSTRACT>

19169 <TITLE>Laterale und vertikale Faziesentwicklung der Rhaet / Unterlias-Sedimentation im Wallberg-Blankenstein-Gebiet (Tegernsee, Nordliche Kalkalpen).</TITLE>
19170 <SOURCE>Mainzer geowiss. Mitt. 17: 53-94. [in German, with English summary]</SOURCE>
19171 <ABSTRACT>By means of microfacies analysis the Upper Rhaetian and Lower Liassic sediments of the Wallberg-Blankenstein region (Tegernsee, Upper Bavaria) are described and classified. The Upper Rhaetian Limestone, developing from the marly / calcareous Kossen basinal sequence, exhibits 10 main microfacies types which partly can be further subdivided. The lateral arrangement of microfacies types displays a mosaic-like distribution. Shoaling upward tendency is obvious already throughout the Kossen beds by the development of reef patches. This pattern also influenced distribution of reefal organisms and sediment types in the superimposed Rhaetian calcareous sedimentation. Ecological restrictions (e.g. water energy) limited, however, a more pronounced occurrence of reef biota and thus inhibited the development of reef patches; reefs. Besides these shallow subtidal patch reefs and related deposits, shoal sediments were deposited in higher energy settings. Dark intertidal algal bindstones and occurrence of black pebbles correspond to the peak of shoaling. The studied Upper Rhaetian limestones reflect the development of a ramp-like initial limestone platform within the Kossen basin. Reefoid development ceases with the discontinuous drowning of the depositional area at the end of the Rhaetian. This led to strongly differentiated shallow to deep subtidal deposits at the beginning of the Liassic, reflecting tectonic uplifts and predepositional Triassic topography. Further break-up and sinking of the Tethyan shelf resulted then in the superposition of bathyal, grey basinal deposits.</ABSTRACT>

19209 <SOURCE>Zbirca ZRC (ZRC Series) 16: 512 pp., 211 pls; Ljubljana (Znanstvenoraziskovalni Center SAZU). ISBN 961-6182-44-7.</SOURCE>
19210 <ABSTRACT>Monographs like that with the description of several hundred species became rare the past times; summarizing monographs on the corals of one country were published the last time hundred years ago. Therefore this book is a great surprise and a great pleasure. In the "Mesozoic Corals of Slovenia" the results of Slovenian Mesozoic coral research of the past 30 years are compiled. But it exceeds a simple compilation: all species are carefully checked, new items added to the synonymy lists and new illustrations provided. Each species is represented at one text page and one page of illustration side by side. The text page contains a synonymy list, a short description, the localities in Slovenia, the age and remarks on the geological setting and environment. A stratigraphical table and a map is provided, where the occurrence of the species concerned is plotted. The illustration page encompasses horizontal and vertical thin sections magnified four or eight times, and microstructure details in greater magnification. The illustrations are good as long the material is well preserved. The latter is maybe the main problem of the monograph: many species are indicated by poorly preserved material and in some cases it is difficult to follow the determination. * The book contains a short but satisfactory description of the geological situation and stratigraphy of the localities where the corals are found. A rich appendix encompasses a list of the described specimens - sorted according to species and generic names, alphabetically and according to their age, and a list of localities, alphabetically and according to the geological unit. A general index summarizes the coral assemblages with their species. * At all, the compilation is very careful: each locality has a number and is plotted at a map. The species description refers to this number. In the list of localities in the description part and in the explanation to the illustration the collection number of the specimens is given. This makes reference to previously published papers and to own notes on the material easy.</ABSTRACT>

19234 <TITLE>Coral zonation of an Oxfordian reef tract in the northern French Jura.</TITLE>
19235 <SOURCE>Facies 50, 3-4: 545-559.</SOURCE>
19236 <ABSTRACT>During the Middle Oxfordian, numerous coral reefs flourished on the northern margin of the Tethys Ocean. The outcrop of Bonnevaux-le-Prieur (northern French Jura mountains) provides a rare opportunity to observe a nearly complete section allowing the installation, evolution and demise of this global carbonate reef rich event to be studied. Quantitative data on coral assemblages together with sedimentological and palaeoecological observations lead to the reconstruction of a reef tract coral zonation. Starting from the outer slope, Dimorpharaea, Microsolena, Dendraraea, Comoseris, and Styliina ecozones are recognized. This new facies model implies a central position for an oolitic shoal in the highest energy zone, within the Comoseris ecozone. Applying this facies model to the sequence stratigraphic interpretation of the vertical succession results in recognising a third-order relative sea-level fluctuation, which can be correlated at least within Lorraine (France) and Switzerland.</ABSTRACT>

19314 <ABSTRACT>The living habits of the bivalves of the ancient coral reef of Laisacker is reconstructed according to the concepts of Kauffman (1969) and their environments according to the model of Schaefer (1963). As is shown by these investigations, all the biocoenoses described by Schaefer are to be found in the Laisacker coral reef complex. The bivalves are differentiated according to ecological-morphological types. It is noticed that types with semiburrowing habits are missing, those living within the sediments are rare. Lithophaga is the only representative of boring types. The major part of the fauna belongs to the group of epifaunal bivalves characteristic for a reef habitat.</ABSTRACT>

19379 <ABSTRACT>First of all, this study brings necessary details about regional stratigraphy. It goes on to reconstitute the paleobiocenoses and the environmental conditions of Bajocian coral limestone deposits: weak currents, fairly high depth, varied substrates, low relief. In the low areas scleractinians disappear and are replaced by sponges, Pseudomelania or pholadomyes communities. In order to explain the particularities of Bajocian constructions, some hypotheses have been put forward, mentioning the slope of the platforms, the speed of growth of organisms and the stability of the sea-level. 19481 <TITLE>An Early Hettangian coral reef in southern France: implications
for the end-Triassic reef crisis.</TITLE>
19482 <SOURCE>Palaios 24: 657-671.</SOURCE>
19483 <ABSTRACT>The oldest known Jurassic coral reef is exposed in the
Ardeche region of southern France. This reef site, consisting of at
least three reefal bodies, is of early Hettangian age and thus
immediately postdates the end-Triassic mass extinction, which is well
known for its catastrophic effect on reef building. Bulk carbonate
carbon isotopes of the limestones below the reef are likely to record
environmental perturbations subsequent to the mass extinction. The main
reef is surprisingly well developed (20m in thickness, 200m in lateral
extent) and composed of at least four genera and six species of corals
? not only holdover genera from the Triassic, but also one newly
evolved genus (Phacelophyllia), contributed to reef construction. Just
like their latest Triassic counterparts, the reef is dominated by
phaceloid corals with a considerable contribution of microbialite. The
reef predates similarly well developed structures by almost ten million
years. The shelf setting of the reef renders it unlikely that refuges
around oceanic islands are needed to explain survival of corals across
the end-Triassic mass extinction. [original abstract]</ABSTRACT>

19507 <TITLE>Nutritional modes in coral-microbialite reefs (Jurassic, Oxfordian, Switzerland): Evolution of trophic structure as a response to environmental change.</TITLE>
19508 <SOURCE>Palaios 17, 5: 449-471.</SOURCE>
19509 <ABSTRACT>Detailed study of Oxfordian coral-microbialite reefs in the Swiss Jura Mountains has identified major paleoecological variations in space and time, which are attributed to environmental changes. Micro- and macroscale semiquantitative analyses of microbialite types, micro-encrusters, bioerosion, corals, and other macrofauna composing the reefal facies were performed. Three main trophic structures (dominant nutritional modes) were recognized: phototrophic-dominated, balanced photo-heterotrophic, and heterotrophic-dominated. A phototrophic (light dependant) faunal dominated reefs growing in pure carbonate and nutrient-poor environments, where sedimentation rate was the main factor controlling reef growth. In mixed siliciclastic-carbonate platform environments, a balanced photo-heterotrophic fauna with periodical shifts to heterotrophic dominated associations was induced by freshwater and sediment run-off into closed, shallow lagoons. In this case, the main factors controlling reef growth were the distribution and accumulation of terrigenous sediment on the platform and / or associated nutrient availability. The balanced photo-heterotrophic structure found in mixed carbonate-siliciclastic settings produced the most diversified reefs, suggesting that these Oxfordian reefs preferentially thrived in water moderately charged with nutrients (mesotrophic environment). In the case of strong siliciclastic accumulation and / or strong increase in nutrient availability, coral reef diversity dropped drastically and heterotrophs dominated the trophic structure. A model of the evolution of trophic structure in these reefs as a function of the governing environmental factors is proposed. Focusing on the dominant nutritional mode at each step in reef evolution allows a detailed characterization of reefal structure and a better understanding of the processes leading to coral reef settlement, development, and demise.</ABSTRACT>

19520 <TITLE>Mikroskleren von Demospongien (Porifera) aus dem basalen Jura der Nordlichen Kalkalpen.</TITLE>
19521 <SOURCE>Geol.-Palaeont. Mitt. Innsbruck 17: 119-142. [in German, with English summary]</SOURCE>
19522 <ABSTRACT>For the first time microscleres of Demospongiae from the Liassic Kirchsteinkalk (Allgau Formation as basin facies to Liassic Kirchstein Limestones) are described and presented by 6 plates. In contrary to previous opinions microscleres can be proved frequently in scarcely diagenetically altered limestones and calcareous marls. With the help of microscleres and in consideration of accompanying megascleres for the first time it was possible to link with recent Demospongiae. Specific microscleres like cricorhabds, toxa, sigmata, diancistors and various chelate scleres, clavidisks, oxasters, sphaerasters, sterrasters and amphiasters are of special importance. With few exceptions these types of microscleres are only known from the Late Tertiary and in some cases even only recently. In particular this

concerns chelate scleres. By evaluation of these microscleres from the Lower Liassic of the Northern Calcareous Alps the following Demospongiae are provable: The Ceratinomorpha are represented by the order Poecilosclerida and their families Myxillidae, Cladorhizidae, Crellidae, Amphilectidae, Desmacellidae and Desmacitidae. Partly correlation on generic level is possible. Within the Tetractinomorpha the order Astrophorida (= Choristida) is represented by the families Geodiidae, Ancorinidae and Pachastrellidae; with the help of microscleres it was possible to prove the families Theonellidae and Corallistidae. The order Hadromerida is represented by the family Clionidae. All the mentioned families are widespread by numerous genera. By the proof of the above mentioned microscleres in the Lower Liassic it was possible to enlighten the evolutionary history of Poecilosclerida and especially Astrophorida. Particular attention is drawn to the sharp faunal break between Triassic and Jurassic, revealed by evaluation of the deep water Porifera (demosponges and hexactinellids).

19586 <SOURCE>Geobios 14, 2: 173-189</SOURCE>
19587 <ABSTRACT>The study of an Upper Kimmeridgian madreporarian fauna collected in the southern french Jura (between Valfin and Belley), allowed: 1) to describe five scleractinian new species: Mitrodendron biennensis nov. sp., Hexapetalum nemorosum nov. sp., Thalamocoenia gironensis nov. sp., Cryptocoenia stelliserrata nov. sp., Columnocoenia miniflora nov. sp. and a new variety of Heliocoenia (Kobycoenia) claudiopolisensis Beauv., 1964, characterized by its small calices; 2) to modify the diagnosis and the systematic position of the species Baryhelium crassa (de From.) which was created as Heterocoenia crassa de From.; 3) to increase of a new species the genus Hexapetalum only known, till now, by its Stramberg Tithon type-species; and 4) to give some palaeoenvironmental conclusions = the Upper Jurassic reef formations in the Southern Jura grew in shallow water characterized by an abundant carbonate sedimentation. Genera associations and distribution confirm the presence, between Oyonnax and Belley, of a low energy area, protected by a barrier reef and, northern of this barrier, of a higher hydrodynamic environment. </ABSTRACT>

19652 <ABSTRACT>Oxfordian shallow-water scleractinian coral association from
the biohermal limestones of the Mt Vrsatec (Czorsztyn Succession,
Slovak sector of the Pieniny Klippen Belt, western Carpathians)
comprises 18 species (among them 2 new) plus 3 taxa determined on the
generic level only. They represent 13 genera and 10 (or 11) families.
The most common are phaceloid coral growth forms from the genus
Thecosmilia Milne Edwards et Haime (family Montlivaltiidae). The
studied fauna appears similar, though less diversified taxonomically,
as compared to those known from the Upper Jurassic shallow-water facies
of many other parts of Europe. In the Pieniny Klippen Belt this type of
coral fauna occurs only in Western Slovakia.</ABSTRACT>

following suborders of the Upper Jurassic corals of wuerttemberg
(SW-Germany): Archaeocaeniinae Alloiteau 1952, Stylinina Alloiteau
1952, Rhipidogyrina Roniewicz1976, Caryophylliina Vaughan &
wells 1943, Amphiastraeina Alloiteau 1952, Faviina Vaughan &
wells 1943
(excl. genus Montlivaltia). The suborder Fungiina Duncan 1884 is not
included. 28 genera and 63 species are examined with consideration of
environmentally and ontogenetically caused variations. One species is
declared invalid, 16 species or subspecies are posed to other, formerly
described species, 8 species are described for the first time out of
the Upper Jurassic of the Swabian Alb and one species is wholly newly
defined. Furthermore, the systematic position of some taxa is changed.

19678 <ABSTRACT>In the present paper the meandroid corals of the suborder
Fungiina Duncan 1884 which are known up to now from wuerttemberg are
shortly presented. 6 of these species cannot be maintained in the list
of corals from wuerttemberg. 1 species is described for the first time
from the higher Upper Jurassic of the Swabian Alb and 1 species is
described wholly new. The most important features of the 5 meandroid
genera occurring in wuerttemberg of the suborder Fungiina are listed.

19715 <TITLE>Preliminary notes on Early and Middle Jurassic corals of the Bakony Mountains (Hungary).</TITLE>
19716 <SOURCE>Hantkeniana 1: 49-58.</SOURCE>
19717 <ABSTRACT>Hettangian, Pliensbachian and Bajocian corals were examined from 6 localities of the Bakony Mountains. All of the suborders existed in Early and Middle Jurassic are present in the 80 specimens. The determined 6 genera belong to 4 suborders. 88% of the fauna is derived from the Domerian formations, but the number of taxa are nearly equal in Carixian, Domerian and Bajocian. Four genera appeared earlier in the Bakony Mountains, than in other areas. Seventy-seven specimens belong to solitary corals, and only 3 specimens are colonial. Two-third of the fauna is hermatypic at the Pliensbachian localities, but at the same time 80% of the specimens are ahermatypic in Bajocian. Fissures of

seamounts and the edge of a seamount are represented at these localities. This means, that the top of the seamounts were not sinking below the depth of 100m during the Pliensbachian, but it may have been below 100m in Bajocian. The elongated morphotypes of corals stabilized themselves by root-like fixation, or the specimens had to be sunk in the loose sediments. Because the loose sediments were rare at the top of seamounts, the corals are sometimes overturned (scoleoid specimens).

- 19847 <ABSTRACT>Grâce à la complaisance de M. Wiedmann, Conservateur du Musée Géologique de Lausanne, que nous remercions ici très vivement, nous avons pu réviser les types de Koby provenant des couches à *Mytilus* des Alpes romanes (Suisse) que nous croyions perdus (L. Beauvais, *Eclog* 1966). Ces 25 échantillons furent décrits par Koby dans la Monographie des Polypiers jurassiques de la Suisse (1883-1889). Les résultats de notre étude sont exposés dans le tableau ci-joint (pages suivantes). * Parmi les 25 espèces de Madréporaires provenant des couches à *Mytilus* (= Dogger) des Alpes suisses, nous en avons reclassé 10 dans des genres différents de ceux que leur avait attribué Koby. Six sont mises dans la synonymie d'espèces déjà connues et les 10 autres sont maintenues dans leur classification générique et spécifique originale. * De plus, du point de vue répartition stratigraphique et géographique, 15 espèces

- sont endémiques, 7 ont été rencontrées dans le Dogger d''autres régions et 3 n''étaient connues jusqu''à présent que dans le Malm. [original text]</ABSTRACT>

- 19873 <ABSTRACT>Jusqu''à présent j'ai trouvé dans les calcaires de Stramberk (localités: Stramberk, Skalicka, Jasenice en Moravie du nord et l'unité silésienne dans les Carpathes occidentales du Flysch) 7 genres et 20 espèces de coraux de la sous-famille Rhipidogyrinae Koby, 1905. J'ai décrit un nouveau genre Ogilviella n.g. et 5 espèces nouvelles. A la sous-famille mentionnée j'ai aussi rapporté le genre Pruvostastraea Alloiteau, 1957 qui jusqu'ici était classé dans la famille Amphiastraeidae Ogilvie, 1897 j'ai rendu plus précises les descriptions des genres Acanthogyra Ogilvie, 1897 et Placogyra Koby, 1904, peu connus, et j'ai aussi décrit des septes apophysaux caractéristiques de la sous-famille Rhipidogyrinae; selon mon opinion les septes lonsdaléoides mentionnés chez les genres Aplosmilia d'Orb., 1849 et Rhipidogyra M. Edw. et H., 1848, ne peuvent être désignés que comme septes lonsdaléoides non-typiques. Les conditions de présence et l'état de conservation de la faune corallienne dans les blocs de calcaires de la région de Stramberk sont brièvement caractérisés.</ABSTRACT>

- 19885 <SOURCE>Acta Palaeontologica Polonica 47, 4: 651-666.</SOURCE>
- 19886 <ABSTRACT>Coralla of the three species of solitary corals described herein from the Sinemurian (Lower Jurassic) of Sicily, i.e., *Haimeicyclus haimeii* (Chapuis and Dewalque 1853), *Stylophyllopsis* sp. cf. *S. rugosa* (Duncan and Wright 1867), and *Stylophyllopsis* sp.A., conform to the overall stylophyllid morphology. Their septa consist of spines that are increasingly covered with sclerenchyme and low in the calice form compact blades. The pattern of diagenetic alteration of septa is diverse but consistent within particular taxa. It suggests that the spectrum of the original microstructures is wider than traditionally suggested for stylophyllids. In *H. haimeii*, the septa are covered with dense granulations and completely recrystallized. Granulations also cover septal faces of *Stylophyllopsis* cf. *rugosa* and have rod-like foundations. In *Stylophyllopsis* sp. A., vestiges of the narrow mid-septal zone (similar to that in minitrabecular corals) occur in the proximal part of larger septa, whereas septal spines which are similar to those in *Stylophyllopsis* cf. *rugosa* occur in their distal parts. Similar diversity of microstructures is reported also in Triassic stylophyllids that have aragonitic coralla. The presence of distinct septal spines along with wide-ranging microstructural diversity of traditional Triassic-Jurassic stylophyllids, casts light on their possible evolutionary relationships, and can be a useful criterion for further revision of the group. For example, Jurassic thecocyathids, considered ancestral to caryophyllinans, share similar spiny/lobate septa with stylophyllids. Also Recent deep-water anthemiphylliids with spiny/lobate septa are strikingly similar to stylophyllids. Although this may be another example of parallel evolution, the separation of anthemiphylliids from other scleractinian clades on a mitochondrial 16S RNA tree topology suggests their ancient roots and enable us to suggest a stylophyllid ancestry. The supposed cyclic pattern of protoseptal insertion in Early Jurassic *H. haimeii* supports the hypothesis of scleractinian-like (and not rugosan) ancestry of the stylophyllid evolutionary lineage.</ABSTRACT>

- 19938 <ABSTRACT>The spongiolitic facies reaches its widest distribution along the epicontinental to pericontinental margin of the Northern Tethys during the Upper Jurassic. These buildups formed by siliceous sponges represent a singular event within the evolution of reef communities during Earth's history. In this paper the present knowledge of causal and environmental aspects of the spongiolithic limestones in Southern Germany and adjacent areas is discussed. With regard to the research project 'Evolution of Reefs' (a major part of the Schwerpunktprogramm 'Biogenic Sediments' established by the Deutsche Forschungsgemeinschaft in 1990) the following genetically and process orientated aspects are of interest: 1) The stratigraphic classification using biostratigraphic, lithostratigraphic and mineralostratigraphic methods. 2) The paleogeography, oceanography and geotectonics along the broad passive northern shelf of the Tethys are discussed with regard to width and stability of the shelf, distance to the land mass and terrigenous influence and sea level fluctuations. 3) Certain sedimentological features seem to be indicative of climatic fluctuations, but this is not always proved by the distribution patterns of organisms. 4) The classical interpretation that spongiolites formed below the wave base gets opposition by the significance of biogenic carbonate crusts as well as sedimentological and paleogeographic arguments. 5) Important sedimentological factors of the Upper Jurassic spongiolites are paleobathymetry, sedimentary cycles, possible control of spongiolite growth by sea level fluctuations, as well as biogenic interactions which probably initiated the fossilization of siliceous sponges as well as the formation of spongiolitic buildups. 6) Paleoecological conditions can be reconstructed by the community patterns of benthonic organisms and substrate control patterns, both changing through time. Phylogenetic innovations of related sponge groups (hexactinellids, lithistide demospongeans) most probably are not responsible for the initial growth of buildups. 7) Comparison of the spongiolites with the laterally and vertically associated coral facies is of major importance for the

- interpretation of controlling parameters (bathymetry, sedimentation rates, nutrient and nutrient availability) of the sponge facies. 8) The genetic significance of diagenetic processes in spongiolites is discussed with regard to early lithification, dissolution, epigenetic dolomitization and dedolomitization.</ABSTRACT>

- 19951 <ABSTRACT>The subdivision and evolution of the south German Upper Jurassic shelf sediments is shown on paleogeographic maps for the Oxfordian, Kimmeridgian and Tithonian (Figs 2-4). Stable elements in this development during these periods were the Franconian South Bavarian limestone platform and the Swabian Marl Basin including the Swabian reef area. A N-S facies section through the South Bavarian limestone platform demonstrates the evolution and the internal structure of the reefs (Fig.5). A diagram of the E-W section along the Southern Franconian Alb and the Swabian Alb exhibits the transition from the Franconian platform into the Swabian marl basin and the Swabian reef area (Fig. 6). The transition from the Swabian marl basin into the Helvetian basin is shown in a N-S profile (Fig.7). The contribution is based on nine facies maps (1:500 000) published by Meyer & Schmidt-Kaler (1989).</ABSTRACT>

- 19976 <SOURCE>Géologie et paléocéologie des récifs [J. Geister & R. Herb (eds)]: 18.1-18.23.</SOURCE>
- 19977 <ABSTRACT>Les biohermes à spongiaires du Jura français appartiennent à l'extrémité occidentale d'une immense zone récifale développée dans le Jurassique supérieur de l'Europe nord-téthysienne. Cette zone s'allonge depuis la France jusqu'à la Roumanie et correspond au domaine de plate-forme externe qui borde, au Nord, la Téthys. C'est en Allemagne (Souabe et Franconie) que les biohermes présentent leur plus grand développement en envahissant la quasi-totalité du Malm (bibliographie in Gwinner 1976). Dans le Jura français, du fait de conditions plus instables et d'une évolution plus rapide du milieu, ils ne prolifèrent que dans l'Oxfordien et sont relayés, dès le Kimméridgien, par des récifs coralliens. De ce fait, les causes de l'apparition, du maintien et de la disparition de ces bioconstructions peuvent être recherchées et analysées plus efficacement. Leur plus faible taille et leur évolution diagénétique peu prononcée permettent d'autre part une étude morphologique structurale et paléocéologique détaillée (Gaillard 1984). - 19989 <SOURCE>www.tesionline.com; 108 pp.www.tesionline.com</SOURCE>
- 19990 <ABSTRACT>The present work is the first paleoecological and systematic study of the Upper Jurassic sponge deposits in western Central Dobrogea. It is a brief synthesis of all the information published yet regarding that subject together with the author's research results, that completes the picture. * In Upper Oxfordian, on a slightly inclined slope-like sea floor, far from the Tethys Ocean northern shore, a great community of sponges has developed. It was a world of high diversity, part of the European Upper Jurassic Sponge Megafacies. Its remains are now enclosed in stromatolithic limestone of microbialithic origin. Even though studies had been carried out in time dealing with the ammonite or brachiopod fauna here, none of them had paid attention to the sponge association. That is the reason for the necessity of that study. * Presenting some similarities with the German or Polish Upper Jurassic sponge fauna, the sponge community in Dobrogea has some particular features that make that eastern part of the European sponge megafacies different from all the rest. The work tries to point out some of them, but not to complete the research, as the sponge fauna here needs revision. [original abstract]</ABSTRACT>

- 20003 <ABSTRACT>The present study deals with paleocological aspects of the Upper Jurassic sponge facies in the western area of the central Dobrogea. There is also, an attempt to include the occurrences of the facies in Dobrogea within the frame of the sponge reefs developed across Europe and beyond, marking a global significance event at the end of Jurassic. An argumentation is also included for the place of the sponge reefs in Dobrogea within the geo-historical evolution of that kind of biological buildings. Finally, there are few comparisons between the sponge facies in Western Dobrogea and its fauna against the status of other occurrences along the siliceous sponge reef belt, in Germany, Poland, Spain.</ABSTRACT>

- 20016 <ABSTRACT>In the Upper Oxfordian, central Dobrogea hosted the far eastern end of the Upper Jurassic Sponge Megafacies. Its closest relations are the occurrences in Poland and those in the Swabian Alb (Germany). The Oxfordian sponge fauna in Dobrogea is also most related with that in Poland and in Germany. However, in Dobrogea, the support of the faunal association was a slight slope, unlikely the rest of the European occurrences. * As the closest Upper Jurassic sponge communities were quite far, their weak influence allowed the development of some different sponge populations in the specific conditions of life here. The differences are mostly related to shape and size, and this study tries to present some of them. * Several genera are considered: Laocoetis, Cribrospongia, Trochobolus, Cnemidiastrum and Melonella. The Cribrospongia phylloidea (Antonescu 1928) species is particularly analyzed and it is suggested that it is only a variety of Cribrospongia reticulata (Goldfuss 1826), and not a separate one. It is, also, particularly analyzed the Trochobolus dentatus (Kolb 1910) species identified in that area. * Unfortunately, diagenetic conditions did not allow the conservation of the skeleton structure. That is why all taxonomical identifications of fossil sponges in Dobrogea, both previous and present ones are based entirely on the macroscopic morphologic descriptions.</ABSTRACT>

20080 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. [#38](#); Gunkel F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
20081 <ABSTRACT>In cores taken around the EybtaI near Geislingen / Steige (Swabian Alb), diagenetic products in Oxfordian to Kimmeridgian microbial sponge mounds and surrounding carbonate sediments are characterized by means of petrographic and geochemical methods. Using

seven microfacies types as reference, respective specific diagenetic sequences and their variations are traced. The general diagenetic history includes early marine phreatic, burial partly hydrothermal and late meteoric stages in all microfacies types. Various controlling factors are effective at different stages and in different dimensions. Early marine diagenesis is largely controlled by rock fabric and composition as well as primary porosity; in contrast, burial and meteoric stages are influenced by fluid chemistry, secondary porosity and regional structural processes. Dolomitized and dedolomitized microbial sponge bafflestones including non-dolomitized, pervasively dolomitized or dedolomitized portions were quantified by digital image analysis. Pathways of the fluids were stylolites and fractures. Spatial heterogeneity of dolomite products increases with dolomite percentage. Dolomite cements of non fabric selective pores did not contribute volumetrically to dolomitization. Pore cementation was controlled by a complex network of factors including effective porosity and total dolomite percentage.</ABSTRACT>

20093 <SOURCE>Paläontologische Zeitschrift 70: 301-313.</SOURCE>

20094 <ABSTRACT>The Lower Jurassic Misone Limestone of the Trento Platform (Southern Alps, Italy) contains a siliceous sponge fauna which is here described. Besides the well-known Moroccan sponge carbonates, these Lower Jurassic spongioliths from the Trento Platform are presently the second mass occurrence of siliceous sponges, which is known from the southern margin of the Tethys. They differ from each other in regard of the composition of the sponge fauna and the absence of microbial crusts in the spongioliths of the Trento Platform. There, hexactinosans and lithistid demosponges occur in equal proportions. Sphinctozoans are another very characteristic element. Because of the richness in both sphinctozoans and siliceous sponges, the Trento occurrences may be considered as a transitional fauna between the late Paleozoic-Triassic sponge fauna dominated by Sphinctozoans and the post-Liassic sponge fauna dominated by more modern groups of siliceous sponges. Two new siliceous sponge genera with their species are established: Misonia baldensis n.gen. n.sp. (Hexactinosa) and Benacia princeps n.gen. n.sp. (lithistid Demospongiae). The rarity of siliceous sponge-dominated spongioliths in the Early Jurassic is due to the restricted occurrence of low energy, deeper shelf areas.</ABSTRACT>

20105 <TITLE>Upper Jurassic Siliceous Sponges from the Swabian Alb: Taxonomy and Paleoecology.</TITLE>

20106 <SOURCE>Palaeontologia Polonica 57: 3-216.</SOURCE>

- 20107 <ABSTRACT>The fauna of siliceous sponges (hexactinellids and demosponges) from the Upper Jurassic of the Swabian Alb is described and revised. It consists of 124 species representing 67 genera. Only 15 species show frequency higher than 1% of the whole assemblage. Nearly all sponges represent groups with solid skeletons: Hexactinosa and Lychniscosa, and lithistid Demospongea. Loose spicules occurring are also described and illustrated. Two new species are proposed: lithistid Amphibleptula jurassica sp.n. and hexactinosan Sphenaulax irregularis sp.n. Several other new species are described in an open taxonomy. The presence or absence of dermal and/or gastral layers of pentactines or stauractines in Hexactinosa and Lychniscosa is of no taxonomic value, because it is mostly a taphonomical phenomenon, and both types of spicules can be present in the same species. Lithification of sponges leading to origin of the so called "sponge mummies" preserves (except in one lyssacinosan sponge) only parts of the sponges delimited by solid skeletal structures. The Oxfordian assemblage is dominated by hexactinosan and lychniscosan sponges, while beginning with the Kimmeridgian lithistid demosponges are very common. The proportion of lithistid sponges in the assemblage increases steadily and the uppermost Kimmeridgian assemblage consists mostly of lithistids. This trend is interpreted here in terms of superimposed bathymetric changes and type of food dominant in the environment: particulate (domination of lithistid demosponges) and colloidal (hexactinellids domination). Ecological analysis of the sponge fauna and sedimentological analysis of sponge-bearing sequences point to a relatively deep-water settling of the Upper Jurassic siliceous sponge biofacies: the most shallow mixed sponge-coral Upper Kimmeridgian assemblages dominated by lithistid demosponges could be from 60-100 meters, while Oxfordian hexactinellid dominated assemblages in the Upper Jurassic is mostly ecological phenomenon since the numerous genera contributing to this assemblage are rooted in the Lower Jurassic at least. Generally high sea level during the Upper Jurassic produced large, relatively deep water areas, remote from the shore and thus with slow sedimentation. Such new habitats suitable for sponges have been colonized by immigrants from refugia existing on continental and island slopes. Large sponge populations were supported by high nutrient availability characteristic for the Upper Jurassic.</ABSTRACT>

20132 <SOURCE>Facies 8: 263-300.</SOURCE>
20133 <ABSTRACT>Microfacies and fossils of the Pantokrator Limestones of the type locality (Pantocrator Mountain, northeastern Korfu/Kerkyra) give evidence of a depositional environment characterized by a carbonate platform with both intertidal and subtidal areas. Vadose diagenesis of some repositioned clasts points to a subaerial exposure of parts of the platform. Five microfacies types can be recognized; four of them are defined by algal aggregate grains, peloids, oncoids, dasycladaceans, porostromate algae and thaumatoporellids. These elements participate in the formation of packstone, grainstone and bindstone fabrics. Microfacies 5 corresponds to an oncolitic grainstone with corals. Two microfacies types, formed in the intertidal environment, yield rounded and angular carbonate clasts, representing different parts of the carbonate platform. Sub- and intertidal carbonates are also represented by clasts found within the deeper marine Siniais Limestones, which very probably formed synchronously with the Pantokrator Limestone; this is indicated by the interfingering of intertidal carbonates (microfacies 2) and micritic limestones with filaments (microfacies 7) southwest of Agios Spyridon.</ABSTRACT>

20158 <SOURCE>Razprave Slov. Akad. Zn. Um IV. Razreda Sazu 44, 1: 285-331</SOURCE>
20159 <ABSTRACT>In the village Gozd on Trnovski gozd plateau, west Slovenia, locality of Liassic reef building corals has been discovered. Twelve species are described systematically, four of them are new: Protoheterastraea trnovensis n.sp., Apocladophyllia gozdensis n.sp., Phacelophyllia bacari n.sp. and Heterastraea angelae n.sp. Corals form at least a 70m long and 4m thick patch reef. It was located at the northern margin of the Dinaric Carbonate Platform. Coral limestone lies directly above "Lithiotid limestone" containing Domerian bivalves. According to this, also the described corals are attributed to the Domerian, i.e. Upper Pliensbachian.</ABSTRACT>

20183 <TITLE>Microfacies, microtaphonomic traits and foraminiferal assemblages from Upper Jurassic oolitic-coral limestones: stratigraphic fluctuations in a shallowing-upward sequence (French Jura, Middle Oxfordian).</TITLE>
20184 <SOURCE>Facies 53, 4: 553-574.</SOURCE>
20185 <ABSTRACT>The characterization and distribution of the microfacies and the microfossil assemblages of a Middle Oxfordian section from Jura Mountains composed by thick oolitic-coral limestones is analyzed. Six microfacies types (mainly grainstones) are differentiated mainly composed by ooids, intraclasts and bioclasts. Foraminiferal assemblages are dominated by agglutinated forms. Benthic microbial communities and sessile foraminifera are the main components of the encrustations. The whole set of microfossil assemblages is typical of shallow subtidal environments rich in "algae"; (Cayeuxia, "Solenopora";, Thaumatoporella, Bacinella, Girvanella and Terquemella) and foraminifera such as Nautiloculina oolithica, Redmondoides lugeoni, Ammobaculites coprolitifformis, Troglotella incrustans and Rectocyclammina. The increasing upward record of debris of algae and Nautiloculina, and the decrease of serpulids, bryozoans, nodosariids and ophthalmidiids indicate a shallowing-upward trend. The stratigraphic distribution of microfacies and microfossil assemblages lead to differentiate two main successive phases. The first is a deeper subtidal environment in an open shelf, while the second is a shallow subtidal environment with evolution from winnowed to more restricted conditions. Microfabrics of radial to concentric ooids upwards in the section correspond to higher energy environments related to an oolitic shoal. This study shows how a very detailed analysis of microfacies, which integrates oolitic features, microfossil assemblages and microtaphonomy is potentially a useful tool for interpreting hydrodynamism and sequence evolution in marine carbonate shallow environments.</ABSTRACT>

- 20196 <TITLE>Depositional environments and diagenesis of Upper Jurassic subsurface sponge- and Tubiphytes reef limestones: Altensteig 1 well, Western Molasse Basin, southern Germany.</TITLE>
- 20197 <SOURCE>Facies 21: 263-284.</SOURCE>
- 20198 <ABSTRACT>An up to 300 m thick Kimmeridgian and Tithonian reef sequence, occurring in the Altensteig 1 well southwest of Augsburg, Bavaria, has been studied with regard to facies types, depositional environment and diagenesis. The reef sequence consists of oolitic sands and sand bars, stabilized by binding organisms and overgrown by siliceous sponges and the enigmatic organism Tubiphytes. The biota consists of siliceous sponges, sclerosponges, bryozoans, brachiopods, molluscs, serpulid and terebellid worms, and echinoderms. Foraminifera exhibit no significant distribution patterns. Algae occur in samples of core 4 (Malm zeta 3). Four facies types (sponge / algal boundstones, tuberoid-peloid wackestone / packstone, ooid-intraclast grainstone and Tubiphytes packstone / boundstone) can be differentiated. The Tubiphytes boundstones represent a particular reef type not yet described in detail from the Upper Jurassic. As can be deduced from subsurface samples and from surface samples (Graibach quarry near Donauwoerth), Tubiphytes formed an organic framework within shallow subtidal environment. The diagenesis of most of the section is characterized by the existence of early marine-phreatic cements, except for the Malm delta / Malm epsilon interval. For this interval, an widespread subaerial exposure of Upper Jurassic carbonates is indicated by the absence of marine-phreatic cements, the occurrence of meteoric-vadose meniscus cements, meteoric-phreatic granular to blocky cements, and of asymmetric radiaxial-fibrous cements.</ABSTRACT>

- 20209 <TITLE>Diagenesis and Fluid Inclusions of Upper Jurassic Sponge-Algal Reefs in SW Germany.</TITLE>
- 20210 <SOURCE>Facies 23: 241-268.</SOURCE>
- 20211 <ABSTRACT>Petrographic and fluid inclusion studies were carried out on limestones, dolomites and dedolomites from Upper Jurassic sponge-algal reefs in SW Germany (Geislingen and Herrlingen areas) to reveal their general diagenetic development and especially their deeper burial history. The first results of this study allow a 12-phase diagenetic history to be reconstructed, which includes two karstification and three dolomitization phases. In addition granular meniscus cements indicate local early diagenetic subaerial exposure and meteoric vadose conditions. A very early dolomitization, which was underestimated up to now due to later diagenetic overprinting, largely closed the primary pores. The characteristic growth of scalenohedral calcite cements (dog tooth) probably indicates alterations in the pore water chemistry which were related to the early dolomitization. Early blocky cements (phase 8) and late diagenetic dolomite (phase 9) were analyzed micro-thermometrically. The measurements of fluid inclusions in blocky cements indicate homogenization temperatures of 55°C to 65°C with salinities of 3.5 to 8.5 weight % NaCl (equiv.). The data indicate their formation under meteoric shallow-burial conditions. The late diagenetic dolomite is characterized by higher homogenization temperatures (65°C to 11[??]°C) and salinities of 4.5 to 15.5. weight % NaCl (equiv.). Data on geothermal gradients during the Upper Jurassic are not available. Therefore a reliable estimation of the formation temperatures and pressures is very difficult. with regard to a normal

geothermal gradient of 30°C/km, formation temperatures of 75°C (Blocky cements) and 105°C (dolomite-II) could be expected by an overburden of 2 km; a fact, which is also known from the general geological data of the study area. As documented in the literature gradients of 50°C-60°C/km can occur in sedimentary basins. Comparable or even higher gradients are locally present in the area of the **Swabian Lineament**. This would reduce the burial depth considerably whereas the formation temperatures are lowered only very little. In this calculation the surface temperature has to be also taken into account.

20223 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. **Gunke**l F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: 215-220.</SOURCE>

20224 <ABSTRACT>About 200 massive limestone bodies (sponge-algal-reefs, **Massenkalk**;) of meters to tens of meters in size were examined in the Eyb valley near Geislingen (Oxfordian-Tithonian). The largest part of the massive limestones is made up of oncoid-lithoclast-oid sands forming large areas (some km²) of mobile **platform sands**;. Different biogenic buildups with varying composition occur within and at the flanks of the sand facies as well as in adjacent basins. Three types of buildups (sponge-algal mud mounds, algal-sponge boundstones, brachiopod-algal-sponge mounds) are found in relation to the sand facies. Zoned sponge-algal mud mounds occur in intraplatform channels (Malm **949**; and **950**;) and nodular sponge-algal mud mounds occur in the marly basin sediments. Another buildup type, rich in brachiopods, may occur in the basin facies. Generally, the composition of massive limestones in the Upper Jurassic of S-Germany must be analyzed in much larger detail for recognizing their real facies distribution.</ABSTRACT>

20237 <ABSTRACT>The recent study deals with the diagenetic development of massive limestones (**sponge-algal reefs**;) in S-Germany. During early diagenesis isopachous, marine-phreatic radial fibrous cements (high Mg-calcite) and peloidal cements were formed. Moreover, very minor dolomite, early equigranular cement, scalenohedral cement and

first syntaxial overgrowth cements occur. Emersion of small areas resulted in the meteoric-phreatic and vadose stage near the Malm δ/ε boundary. During the shallow burial stage differential compaction (at about 200 m) between bedded and massive facies and the main dolomitization of massive limestones occurred. Pore fluids migrated along microfractures and micropores. During increasing burial, massive replacement dolomite was formed. Its crystals show a characteristic homogeneous cathodoluminescence. Deeper buried Malm dolomites (temperatures >50°C) in the Molasse basin show increased crystal size, increase in Fe and Mg contents, crystallinity and ordering. Isotopic data confirms the interpretation of the replacement character of the main dolomitization phase. Formation temperatures of 40-90°C are shown by the homogenization temperatures of 2-phase inclusions. Salinities (3.5-14 weight-% NaCl-equiv.) indicate primary marine to highly concentrated waters. A hydrothermal dolomitization (temperature of formation >85°C) only occurred in the deeply buried (>3,000 m) areas in the eastern Molasse basin. During karstification meteoric waters from the surface could percolate along tectonic fractures resulting in late cementation by calcite blocky cements (formation temperature of <40°C) and dedolomitization.

20249 <SOURCE>Berliner geowissenschaftliche Abhandlungen E19: 1-101.</SOURCE>

20250 <ABSTRACT>The Central Dobrogea in Eastern Romania exhibits the easternmost occurrence of Upper Jurassic microbialite / siliceous sponge facies (spongiolite facies) in Europe. The spongiolites are part of the Lower to Upper Oxfordian Casimcea Fm. which was deposited on a gently westward dipping carbonate platform (homoclinal ramp). This platform was surrounded by deep marine basins in the south, west and north, while to the east the existence of a land area with low relief is assumed. The gently sloping carbonate ramp shows an E-W facies zonation. A lagoonal belt is followed towards the open sea by a coral patch reef belt, a bioclastic-oolitic sand belt, and a spongiolitic belt. 20261 <TITLE>Microbialites and Micro-encrusters in Shallow Coral Bioherms (Middle to Late Oxfordian, Swiss Jura Mountains).</TITLE>

20262 <SOURCE>Facies 40, 1: 101-129.</SOURCE>

20263 <ABSTRACT>Benthic microbial crusts (microbialites or microbolites) are an important component of Middle to Upper Oxfordian shallow-water coral bioherms in the Swiss Jura. They display stromatolitic (laminated), thrombolitic (clotted), and leiolitic (structureless) fabrics, which

are distributed heterogeneously throughout the studied sections. The bioherms can be subdivided into coral-microbialite facies, microbialite-dominated facies, and sediment matrix. Macroscopic and microscopic study reveals that microbialitic encrustations commonly occur in two layers. The first one is directly in contact with the substrate and composed of leiolite (locally stromatolite) and a well-diversified micro-encruster fauna; the second one fills the remaining porosity partly or completely with thrombolite and low-diversity micro-encrusters. The growth of the first layer accompanies the growth of the coral reef and thus formed under the same environmental conditions. The second layer is the result of a moving encrustation front filling the remaining porosity (micro- and macrocavities) inside the reef, below the living surface. Both layers play an important role in early cementation. Phototrophic cyanobacteria probably intervene in the formation of the first encrustation zone, whereas heterotrophic bacteria associated to acidic, Ca²⁺-binding macromolecules in biofilms are thought to contribute to the thrombolite inside the reef body. When coral growth cannot take pace with microbialite development, the thrombolite front reaches the surface of the construction and finally covers the reef. The result is a thick interval of thrombolite, which can be interpreted as being related to an ecological crisis in coral-reef evolution. [part of extensive summary]

20274 <TITLE>Fazieswandel und Probleme der Stratigraphie im Obermaalm (Tithon) zwischen Solnhofen und Neuburg / D. (Bayern).</TITLE>

20275 <SOURCE>Erlanger geologische Abhandlungen 123: 1-49. [in German, with English abstract]</SOURCE>

20276 <ABSTRACT>Based on new drill core holes an attempt has been made to elucidate the intricate facies interrelationships of the Upper Maalm between Solnhofen and Neuburg / Donau. In the Solnhofen-Langenaltheim Basin the facies changes in the west-east direction from marl-rich shales to pure lithographic limestone of the Upper Solnhofen beds (Zeta 2b). Despite similar configuration of the basin bottom the lithographic limestone in the east measures twice the thickness of the marl-rich shales in the west. These important differences in thickness can therefore only be explained by a heavier compaction of the marl-rich sections in the course of diagenesis. The differences in relief thus generated within the basin were subsequently leveled out by differently thick sediments of the Hangende Krumme Lage (lump structures) and particularly the Mornsheim beds (Zeta 3) (see fig. 5 and 7). Even more pronounced is, of course, the change in facies between different basins. Fig. 9 shows the differing sequence in the Maalm Zeta 2 and 3 above the bedded limestone of Zeta 1. While in the protected Solnhofen basin pure lithographic limestone was deposited the same series in the Rennertshofen basin was strongly affected by the reef: the rough bituminous shales rich in radiolarians and sponge-rhaxes are repeatedly interspersed with fine and coarse reef detritus beds. Here in contrast to the situation at Solnhofen the nannoplankton is present throughout. Discernible are only coccoliths and spiny, thin-skinned dinoflagellates. It can, however, be surmised that red tides of thick-skinned and pore-rich dinoflagellates (Tasmanacea) can be held responsible for the generation of bitumen and fine lamination (Meyer & Schmidt-Kaler 1993), similar to the situation in the

- Posidonienschiefer (Toarcian). From the Malm Zeta 3 upward coral biostromes growing on decaying sponge reefs furnish reef debris to all sides. Similar bioturbated beds point to a better oxygenation of the sea bottom. Overlying these rocks are the marly limestones and shales of Malm Zeta 4 and 5 whose delineation becomes yet more difficult owing to the small scale facies changes (fig. 10). A clear cut double cycle of bedded limestones and shales (Fesefeldt 1962) does not exist. In the holes drilled near the reef (Spindeltal and Finkenstein) the fine debris content extends upward into Malm Zeta 4 and 5 and demonstrates that the reef evolution and development here in the south lasted longer. Further to the south underneath the Tertiary Molasse sediments, up to more than 500m thick sponge and coral reef detritus limestones have been proved (Meyer & Schmidt-Kaler 1989 and 1990). In the Appendix (chapter 5) as well as on plates 2 to 10 the drill hole columns and special investigations (Macro-, Micro-, Nannofacies, clay minerals, geochemistry, palynology) are presented.

20326 <TITLE>Kimmeridgian-Valanginian reef corals from the Moesian Platform from Bulgaria.</TITLE>

20327 <SOURCE>Annales Societatis Geologorum Poloniae 78, 2: 91-134.www.asgp.pl/2008/78_2/contents.html</SOURCE>

20328 <ABSTRACT>The coral fauna of the Late Kimmeridgian-Valanginian interval from the Slivnitsa Formation, Lyubash monocline, SW Moesian Platform, is presented. Coralliferous interbeds from a continuous, over 350m thick sequence of well-bedded platform limestones, cropping out near the village of Lyalintsi, yielded 72 species (29 determined in open nomenclature) classified into 50 genera and 23 families belonging to the orders Scleractinia and Hexactinellaria. The following genera and/or species are described as new: *Epistreptum communeformae* gen. et sp. n., *Lyubasha gracilis* gen. et sp. n., *Oedalmiopsis cretacea* gen. et sp. n., *Siderastreites lyalintensis* gen. et sp. n., and *Latomeandra obliqua* sp. n., *Microphyllia elevata* sp. n., *M. amalla* sp. n.; a new family *Solenocoeniidae* is erected. The fauna shows a mixed Late Jurassic/Early Cretaceous character, with Jurassic taxa prevailing over Cretaceous taxa. Epithecate phaceloid (pseudocolonial), lamellar, and ramose (colonial) growth forms dominate over massive (hemispherical) and solitary corals. Rich microencrusting organisms are associated. The predominantly pelmicritic sediment of thrombolite macrofabric, and the character of the fauna show that the palaeoenvironment was situated below wave base. The stratigraphical distribution of the Cretaceous coral taxa is conformable with the micropaleontological (foraminifera, calcareous dinocysts, diploporids) stratigraphical zonation established in the Slivnitsa Formation. - 20352 <TITLE>Scleractinian corals of suborders Pachythecaliina and Rhipidogyrina: discussion on similarities and description of species from Stramberk-type limestones, Polish Outer Carpathians.</TITLE>
- 20353 <SOURCE>Annales Societatis Geologorum Poloniae 73, 3: 193-217.</SOURCE>
- 20354 <ABSTRACT>Similarities between scleractinian corals from extinct suborders Pachythecaliina Eliasova 1976 and Rhipidogyrina Roniewicz 1976 are discussed. Corals of the former suborder are considered by some authors as possible descendants of Palaeozoic Rugosa because of their unusual skeletal characters. Some rhipidogyrinans, especially the family Aulastraeoporidae, despite different septal microstructure, share more common features with pachythecaliinans than with other scleractinians. The following skeletal features are discussed to show similarities between these two suborders: (1) wall microstructure and its relations to septa, (2) corallite bilateral symmetry, (3) marginarium, (4) lonsdaleoid and apophysal septa, and (5) internal septal margin. These similarities can be explained by convergence, although phylogenetic relationships of both suborders can not be excluded. This hypothesis needs to be verified by more studies, especially on early blastogeny of rhipidogyrinans and wall microstructure of pachythecaliinans. The systematic part gives descriptions of discussed corals occurring in the Stramberk-type limestones, Polish Outer Carpathians (Tithonian-?Berriasian, ?Valanginian). Similarly as in the Stramberk Limestone (Moravia), pachythecaliinans are highly diversified (17 species, 12 genera, including Pachythecophyllia eliasovae n.gen., n.sp.). Rhipidogyrinans are represented by 4 species of 4 genera, including ?Ogilvinella morycowae n.sp. [original abstract]</ABSTRACT>

- 20367 <ABSTRACT>Debris-flow sediments belonging to the Upper Cieszyn Limestone (Berriasian) are exposed nearbywiec (Polish part of the Outer Western Carpathians). The debris-flow sediments include clasts of bioclastic limestones (boundstones) derived from both microbial-sponge mud mounds and coral-algal reefs. The microcruster assemblage Lithocodium aggregatum - Bacinella irregulare has been found in clasts from coral-algal reefs. This assemblage unequivocally proves the presence of shallowing-upward reefal sequences on the Silesian Ridge. The development of the coral-algal reefs was probably a

- consequence of intense aggradational growth of microbiolite-sponge mud mounds, accompanied by intense uplift movements of the neo-Cimmerian phase.

20380 <ABSTRACT>The metamorphic basement of the Aridhea Loutra Unit (Almopia Subzone) is followed by two thick "molassic type" siliciclastic transgressive series of Upper Jurassic-Lower Cretaceous age. In the Northwestern coarse-grained series, the following members are distinguished: Ophiolitic conglomerates "transgressive basal unit ". Reef limestones with Corals of Upper Jurassic age, marking the first clastic-carbonate, transitional episode. Quartzitic breccia, accumulated during episodes of high discharge in marine environment. Quartzitic sandstones and mudstones. Neritic limestones with Foraminifera and pollen of Late Aptian - Middle Albian age represent the second clastic-carbonate, transition episode.</ABSTRACT>

20391 <TITLE>Oxfordian to Valanginian palaeoenvironmental evolution on the western Moesian carbonate platform: a case study from SW Bulgaria.</TITLE>
20392 <SOURCE>Annales Societatis Geologorum Poloniae 78, 2: 65-90. www.asgp.pl/2008/78_2/contents.html</SOURCE>
20393 <ABSTRACT>Three sections (Rebro, Lyalintsi and Velinovo) of the Upper Jurassic-Lower Cretaceous carbonate sequences from the Lyubash unit (Srednogorie, Balkanides, SW Bulgaria) have been studied for elucidation of biostratigraphy and palaeoenvironmental evolution. Palaeontological studies of foraminifera, supplemented by studies of calcareous dinoflagellate cysts and corals, enabled the determination of the Oxfordian-Valanginian age of the analysed sequences. They were deposited on the Dragoman Block (western part of the Moesian Platform), and during Mid-Late Cretaceous included to the Srednogorie. A possible Middle to Late Callovian age of the lowermost part (overlying the Bajocian-Lower Bathonian Polaten Formation) of the studied sections assumed till now has not been confirmed by the present studies. Eleven facies have been distinguished and attributed to depositional environments. Marine sedimentation on a homoclinal ramp started in the Oxfordian and till the Early Kimmeridgian - in all three sections - was dominated by fine-grained peloidal-bioclastic wackestones to grainstones. Since the Late Kimmeridgian, when a rimmed platform

established, facies pattern underwent differentiation into (i) the inner platform (lagoon and tidal flat facies) – only in Velinovo, (ii) reef and peri-reef facies/bioclastic shoals – mainly in Lyalintsi, and (iii) platform slope – mainly in Rebro. Sedimentation generally displays a shallowing-upward trend. Two stages in evolution of the rimmed platform are postulated. The mobile stage lasting till the Tithonian/Berriasian boundary was followed by a more stable stage in the Berriasian to Valanginian time. Reefs are developed mainly as coral-microbial biostromes, lower coral bioherms or coral thickets, in the environment of moderate energy and sedimentation. They contain highly diversified corals (72 species) [see Roniewicz (2009)]. Microbialites contributed to the reef framework, but they never dominated. Locally, microencrusts and cement crusts formed important part of reefal framework. During the mobile stage of the platform evolution a relative sea-level rise interrupted reef development, as evidenced by intercalations of limestones with Saccocoma. During the second stage high carbonate production and/or regressive eustatic events, not balanced by subsidence, decreased accommodation space, limiting reef growth and enhancing carbonate export to distal parts of the platform.  20418 <SOURCE>Coral Research Bulletin 04: 39-68.</SOURCE>
 20419 <ABSTRACT>Four coral assemblages are reported from Aptian and Albian transgressive deposits in the Helicon Mountains (Boeotia, Greece). Their origin and composition are discussed. 88 species in 33 genera of the order Scleractinia are briefly described, of which 56 species are already known from other Cretaceous faunas. 32 species were determined only generically. The stratigraphical and geographical relations of the assemblages to other faunas from the Cretaceous of Eurasia are discussed in detail. The paper represents the second systematical record of Cretaceous corals in Greece after Hackemesser 1936.</ABSTRACT>

20508 <TITLE>Persistence of coral-rudist reefs into the Late Cretaceous.
</TITLE>
20509 <SOURCE>Palaios 05: 98-110.</SOURCE>
20510 <ABSTRACT>During the Early Cretaceous, coral-algal communities occupied
deeper water habitats in the reef ecosystem, and rudist communities
generally populated the shallow-water, carbonate-sand substrates.
During the middle Cretaceous, however, coral-algal communities became
less common, and Late Cretaceous reef communities consisted of both
rudist-dominated and rudist-coral communities. In the Pyrenean basins
and other basins in the Mediterranean, coral associations co-existed
with rudists forming complex buildups at the shelf-edge. In some parts
of these buildups corals were nearly as abundant as rudists; in some
complex buildups large coral colonies encrusted the rudists. Behind the
shelf margin cylindrical, elevator rudists dominated the lenticular
thickets that were interspersed with carbonate sands. Global changes in
oceanic conditions, such as marine productivity and oxygen content, may
have stressed the deeper coral-algal reef communities leaving rudists
as the major shallow reef biota in Caribbean reefs. However, the
co-occurrence of corals with rudists in these Pyrenean complex buildups
suggests that corals were able to compete with rudists for resources.
The corals in the complex buildups generally belong to genera different

- from those in the coral-algal communities. Perhaps this ecological stress in the mid-Cretaceous resulted in the evolution of new coral taxa.</ABSTRACT>

- 20522 <SOURCE>Acta Palaeontologica Polonica 58, 4: 425-436.www.geo.uw.edu.pl/agp/table/abstracts/58-4.htm</SOURCE>
- 20523 <ABSTRACT>Lower Cretaceous deposits of the Puez section in the Dolomites (northern Italy) yielded a rich ammonoid fauna (28 genera, n=424) showing unique epifaunal encrustations by the ahermatypic solitary scleractinian ?Cycloseris Lamarck, 1801. The coral encrusted only the outer shell surfaces of the ammonoids; the inner surface remained unaffected. such a Cretaceous community and the relationship between the two fossil groups are described for the first time. The shells of dead ammonoids sank to the sea bottom and became colonized by the coral larvae, as documented by the location of the epibionts on only one side of the shells. The coral was fixed to the ammonoid shell for its entire life. Only the "sediment free" upper side of the ammonoid shells could be inhabited by epibionts such as corals and serpulids. The encrustation of ammonoid shells by the bivalve Placunopsis represents a different situation in that both sides of the ammonoid shells were affected, pointing to encrustation of floating ammonoids. This long-term infestation in the water column contrasts with coral settlement on the sea-floor. Ammonoid specimens encrusted by Placunopsis never exhibit encrustation by corals. The ammonoid-coral relationship from the Dolomites is documented from the Valanginian to Aptian interval. examples of coral epibionts on ammonoids and other fossil groups throughout the geological column are briefly reviewed. 20549 <ABSTRACT>The biostratigraphy of Aptian and Albian limestone from Slovenski vrh is treated. Lower Orbitolina Limestone contains foraminifers typical for Lower Aptian. Upper Orbitolina limestone contains foraminifers of Upper Aptian - Lower Albian age. Next to it the reef fauna of corals and rudists has been found ascribed to Aptian and Albian stages. 13 species of foraminifers have been determined, 6 coral species have been systematically described (among them 2 new species), as well as rudists which belong to 4 genera. From the paleoecological aspect the limestone with orbitolinas was deposited in a lagoon of the shallow Dinaric platform, and in the favorable circumstances the reef organisms (rudists and corals) built the smaller patch reef.</ABSTRACT>

20560 <TITLE>Coral-Rudist Bioconstructions in the Upper Cretaceous Haidach Section (Gosau Group; Northern Calcareous Alps, Austria).</TITLE>
20561 <SOURCE>Facies 36, 1: 69-90.</SOURCE>
20562 <ABSTRACT>In the area of Haidach (Northern Calcareous Alps, Austria), coral-rudist mounds, rudist biostromes, and bioclastic limestones and marls constitute an Upper Cretaceous shelf succession approximately 100 meters thick. The succession is part of the mixed siliciclastic-carbonate Gosau Group that was deposited at the northern margin of the Austroalpine microplate. In its lower part, the carbonate succession at Haidach comprises two stratal packages that each consists, from bottom to top, of a coral-rudist mound capped by a rudist biostrome which, in turn, is overlain by bioclastic limestones and, locally, marls. The coral-rudist mounds consist mainly of floatstones. The coral assemblage is dominated by *Fungiina*, *Astraeoina*, *Heterocoeniina* and *Agathelia asperella* (*Stylinina*). From the rudists, elevators (*Vaccinites* spp., radiolitids) and recumbents (*Plagioptychus*) are present. Calcareous sponges, sclerosponges, and octocorals are subordinate. The elevator rudists commonly are small; they settled on branched corals, coral heads, on rudists, and on bioclastic debris. The rudists, in turn, provided settlement sites for corals. predominantly plocoid and thamnasterioid coral growth forms indicate soft substrata and high sedimentation rates. The mounds were episodically smothered by carbonate mud. Many corals and rudists are coated by thick and diverse encrustations that indicate high nutrient level and/or turbid waters. The coral-rudist mounds are capped by *Vaccinites* biostromes up to 5m thick. The establishment of these biostromes may result from unfavourable environmental conditions for corals, coupled with the potential of the elevator rudists for effective substrate colonization. The *Vaccinites* biostromes are locally topped by a thin radiolitid biostrome. The biostromes, in turn, are overlain by bioclastic limestones; these are arranged in stratal packages that were deposited from carbonate sand bodies. Approximately mid-section, and interval of marls with abundant *Phellopteria* is present. These marls were deposited in a quiet lagoonal area where meadows of sea grass or algae, coupled with an elevated nutrient level, triggered the mass occurrence of *Phellopteria*. [fragment of extensive summary]</ABSTRACT>

20626 <SOURCE>N. Jb. Geol. Palaeont. Mh. 1979, 2: 97-108.</SOURCE>

20627 <ABSTRACT>A specimen of a typical chaetetid Chaetetopsis favrei (Deninger 1906) with abundant monaxon spicules preserved within the calcareous skeleton has been recovered from the Barremian (L. Cretaceous) of Crimea. This confirms the idea of Hartman & Goreau (1972) of the sclerosponge affinity of chaetetids. The genus Chaetetopsis Neumayr 1890, and suprageneric categories in chaetetids have been revised including a redescription of Chaetetopsis favrei.

- 20666 <ABSTRACT>Two boulders of shallow-water carbonates found in Campanian olistostromes near Torollola, a small village 2.5 km south of Poble de Segur (Southern Pyrenees, northern Spain) contained the coralline demosponges *Vaceletia crustans* n.sp. and *Spirastrella* (*Acanthochaetetes*) cf. *wellsi* Hartmann & Goreau 1975. *Vaceletia crustans* n.sp. is characterized by a stromatoporoid basal skeleton originally consisting of aragonite. The spicular skeleton consists of oxeate megascleres. The sclere type and the sclere arrangement is typical for haplosclerid demosponges. *Spirastrella* (*Acanthochaetetes*) cf. *wellsi* Hartmann & Goreau 1975 has a chaetetid skeleton consisting of high-Mg calcite. In contrast to some Mid-Cretaceous forms, the specimens from the Campanian of Torollola do not incorporate the spicules in their basal skeletons. There are no significant differences to the Recent *Spirastrella* (*Acanthochaetetes*) *wellsi* Hartmann & Goreau 1975 from the Pacific. </ABSTRACT>

- 20691 <SOURCE>Eclogae Geologicae Helvetiae 84, 3: 837-849 </SOURCE>
- 20692 <ABSTRACT>A phosphatized coralline sponge discovered in the Plattenwald

- bed of the Mid-Cretaceous Garschella Formation in Vorarlberg (Austria) is distinguished from other coralline sponges by the presence of large calicles (mean diameter value - 1,5mm) which increase in number during the growth by the intercalation of basically v-shaped tubes. The calicles are divided by regular spaced tabulae and the specimen resembles, therefore, the Paleozoic cnidarian taxon Favosites. It is described here as Chaetetopsis favositiformis n.sp. In contrast to most known representatives of the coralline sponges, Chaetetopsis favositiformis n.sp. occurs in association with a non-reef-type open-marine fauna.</ABSTRACT>

20820 <TITLE>Some Scleractinian corals from Lovech Urgonian Group (Balgarene Formation) from the area of V. Tirnovo-Gabrovo (Central Fore-Balkan, Bulgaria).</TITLE>
20821 <SOURCE>Godishnik na Sofijskiya Universitet Kliment Okhridski, geologo-geografski fakultet (1: géologie) 94, 1: 5-25.</SOURCE>
20822 <ABSTRACT>In the district of the towns V. Tirnovo and Gabrovo (Central Fore-Balkan) 9 scleractinian species from the Lovech Urgonian Group are described. In the area this lithostratigraphic unit is characterized by the development of mainly carbonate/siliciclastic shallow water sequences, deposited during the Lower Barremian to Lower Aptian stages. The coral fauna is derived from the siliciclastic sediments in the lower part of the Balgarene Formation from Lovech Urgonian Group, which is of Early Barremian age. The scleractinian corals are dominated by colonial forms. They are reported from three localities: Pushevo, Sedjankovci and Vetrovo and comprise 9 genera, belonging to four suborders. Some species are not described in Bulgaria until now.</ABSTRACT>

20859 <TITLE>wellsimeandra gen.n. du Barrémien de la Région de Veliko Tirново (Prébalkan Central).</TITLE>
20860 <SOURCE>Comptes Rendus de l'Académie Bulgare des Sciences 56, 1: 61-66.</SOURCE>
20861 <ABSTRACT>A colonial meandroid scleractinian coral *wellsimeandra morycowae* gen.n. et sp.n. from the district of Veliko Tirново (Central

Forebalkan, Bulgaria) is described. The new genus belongs to suborder Rhipidogyrina Roniewicz, 1976, family Trochoidomeandridae Turnsek, 1981. It distinguishes from the other two genera in the family - Trochoidomeandra Morycowa, 1971 and Rhipidomeandra Morycowa & Masse, 1998 by the simultaneous presence of long and short radially arranged series, tectiform collines and microstructure (mid-septal clear zigzag line located between two dark parallel lines). The corallums are obtained in the terrigenous sediments from the lower part of the Lovech Urgonian Group - the Balgarene Formation, which is of Early Barremian age. [original abstract] </ABSTRACT>

20912 <SOURCE>Journal of Paleontology 73, 6: 1029-1041.</SOURCE>
20913 <ABSTRACT>Extremely well-preserved specimens of the species *Rennensismilia complanata* and *Aulosmilia cuneiformis* occur in Santonian (Upper Cretaceous) strata of the Lower Gosau beds, near Gosau, Austria. Two of these, here reported, have aragonite skeletal mineralogy and skeletal structures that are typical for their families, and, in addition, show distribution of trace elements (Sr and Mg above all) that confirm the biogenic origin of these structures observed. *R. complanata* also has proteinaceous matrix surrounding bundles of skeletal crystallites. Matrix is most abundant along the axial plane of septa, which also is the first-formed part of each septum. Although *A. cuneiformis* lacks observable organic matrix materials, its skeletal structure and its distribution and amount of trace elements are analogous to that seen in *R. complanata* and also in modern corals.</ABSTRACT>

20938 <SOURCE>Revue de Paleobiologie 25: 791-838.</SOURCE>

- 20939 <ABSTRACT>The paper deals with scleractinian corals from the Upper Schrattekalk (Early Aptian) in the area of Hergiswil near Lucerne in the Helvetic Zone of the Swiss Alps. The coral assemblage is dominated by small lamellar and massive colonies, in places grouped in small lenses, mainly from suborder Microsolenina and Astreaeina. From 38 taxa, 28 species have been described (including 2 new species) and ten at the generic level, only. The identified coral taxa are characteristic of Urgonian facies of the European and near East Tethyan realm.</ABSTRACT>

- 20952 <ABSTRACT>Actinaraeopsis ventosiana is a new scleractinian coral species from the Lower Cretaceous shallow-water limestones of the Mont Ventoux (Provence, SE France). To date only two Late Jurassic species of this genus have been known, i.e. Actinaraeopsis araneola Roniewicz and A. exilis Roniewicz. The new species shows some similarity to the Jurassic species A. araneola, but differs in microstructure details and morphometric parameters.</ABSTRACT>

- 20964 <SOURCE>Lethaia 41, 1: 1-14.</SOURCE>
- 20965 <ABSTRACT>The upper Santonian Hofergraben Member (Eastern Alps) provides an example of a soft-substrate habitat suited mainly for solitary corals (Cunnolites), for colonial forms of solitary coral-like shape (Placosmia, Diploctenium), and for colonial corals of high sediment resistance (e.g. Actinacis, Pachygyra). The Hofergraben Member consists mainly of silty-sandy marls of wave-dominated, low-energy shore zone to shallow neritic environments. Substrates of soft to firm mud supported level-bottoms of non-rudist bivalves, gastropods, solitary corals, colonial corals, rudists, echinoids, and benthic foraminifera. Boring and/or encrustation of fossils overall are scarce. In the marls, Cunnolites is common to abundant. Both a cupulate shape and a lightweight construction of the skeleton aided the coral to keep afloat soft substrata. Cunnolites taphocoenoses are strongly dominated by small specimens (about 1-3 cm in diameter). Cunnolites was immobile and mostly died early in life upon, either, smothering during high-energy events, rapid sedimentation associated with river plumes, or by toppling and burial induced by burrowing. Comparatively few large survivor specimens may show overgrowth margins interpreted as records of partial mortality from episodic sedimentation or tilting on unstable substrate. Scattered pits and scalloped surfaces on large Cunnolites may have been produced, in some cases at least, by predators

- (durophagous fish?). Post-mortem, large Cunnolites provided benthic islands to corals, epifaunal bivalves and bryozoans. In a single documented case of probable in vivo contact of Cunnolites with the colonial coral Actinastraea, the latter prevailed.

21055 <SOURCE>Godishnik na Sofijskija Universitet " Kliment Okhridski ", biologo-geologo-geografski Fakultet, Kniga 2: Geologija 82, 1:

- 197-213.</SOURCE>
- 21056 <ABSTRACT>Nine outcrops of Scleractinians are found in the North European type of Upper Cretaceous in the Pleven district. Eleven species have been defined; three of them are Lower Cenomanian, two are Lower Campanian, 2 - Upper Campanian, 4 -Lower Maastrichtian and 2 - Upper Maastrichtian. Upper Maastrichtian species are also found in the Lower Maastrichtian. There is no evidence for two of the Cenomanian species as to which ecological groups belong. All the other species are ahermatypic. The Lower Campanian species pertain to the Parasmilia ahermatypic cosmopolitan genus and the Upper Campanian and the Maastrichtian - to the Caryophyllia ahermatypic cosmopolitan genus. The development of scarce fauna can be explained mainly with the lack of hard substratum for fixation. The outcrops of Upper Cretaceous Scleractinians pertain to the Northern paleofaunistic region.</ABSTRACT>

- 21095 <ABSTRACT>Diplocoeniella gen.n. is newly described from the Barremian

and Lower Aptian of the Polish Outer Carpathians. This genus includes cerioid colonies, plocoid in appearance, characterised by intracalicular budding, septoparathecal wall of corallites, costosepta consisting of branching trabeculae, typical of rhipidogyrin corals, styliform columella, extended, tabuloid dissepiments. One new species of this genus, *Diplocoeniella gerochi* sp.n. is described herein.

21107 <SOURCE>FC&P 33, 1: 9.</SOURCE>

21108 <ABSTRACT>[born] 18. 05. 1924 at Bergreichenstein / Böhmerwald, [died] 18. 11. 2002 at Staufeu / Breisgau. * In 1946/47 Prof. Geyer started his study of Biology at the Technische Hochschule Stuttgart, but changed to Geology and Palaeontology in 1948. with his thesis "Die oberjurassische Korallenfauna von Württemberg" he finished his studies in 1952. Between 1952 and 1961 he worked as assistant professor at the Geologisch-Paläontologisches Institut of the Technische Hochschule Stuttgart. In 1959 he finished his Habilitation with a work; "Monographie der Perisphinctidae des unteren Unterkimmeridgium (wei ßer Jura γ, Badenerschichten) im süddeutschen Jura". With that the venia legendi was bestowed on him. Thesis and Habilitationsschrift already marked his main field of work: Mesozoic corals and ammonoids, but he was interested in stratigraphy and paleogeography as well. widely known is his textbook "Grundzüge der Stratigraphie und der Fazieskunde", which was published in two volumes in 1973. List of his works contains 115 publications. * His obituary has been published by Winfried Reiff, Stuttgart: Reiff W. 2003: Otto Franz Geyer, 1924-2002; Jh. Ges. Naturkde Württemberg 159, pp 291-303, 1 fig., 1 portrait; Stuttgart.</ABSTRACT>

21211 <TITLE>The Barremian coral fauna of the Serre de Bleyton mountain range
(Drôme, France).</TITLE>
21212 <SOURCE>Annalen des naturhistorischen Museums in Wien 112: 575-612.
</SOURCE>
21213 <ABSTRACT>The corals of the Serre de Bleyton mountain range are
determined and described. The fauna consists of very small coral
remains and fragments rarely exceeding one centimetre in size. It is
clearly dominated by a few solitary and small phaceloid forms, while
other growth forms are very rare. The fauna comprises 26 species in 16
genera of the suborders Amphiastrea, Archeocaeniina, Caryophylliina,
Faviina, Fungiina, Microsolenina, and Stylinina. with the exception of
one Amphiastrea species, all corals have small to very small calices.
The faunal composition is typical of Hauterivian to Early Albian coral
faunas. Palaeobiogeographically they are related to Barremian-Aptian
faunas of the central Tethys and the western hemisphere. [original

21224 <TITLE>Valanginian-Hauterivian scleractinian coral communities from the Marseille region (SE France).</TITLE>
21225 <SOURCE>Cretaceous Research 30, 1: 178-192.</SOURCE>
21226 <ABSTRACT>Coral beds associated with Valanginian and Hauterivian platform carbonates from the Marseille region show two faunal assemblages corresponding with a Stylosmilia-Baryphyllia community (late Valanginian) and a Mesomorpha-Dimorpharaea community (early Hauterivian). The stratigraphic position of this fauna is based on the associated microfossils and correlation with ammonite-bearing beds. The internal architecture of the coral beds is loosely packed, the geometry of the corresponding bodies is tabulate and flat, and their depositional setting being the deeper, muddy part of the infralittoral zone. The biostratigraphic significance of the encountered species which include: stylosmilia cf. corallina, Eocomoseris raueni, Mesomorpha ornata, Dimorpharaea catalaunica and Baryphyllia haimei, is low and our data tend to broaden the stratigraphic range of some of them. Assuming that the corresponding species were zooxantellate suggests the existence of an oligotrophic rather than a mesotrophic oceanic regime, postulated by some workers for the time span in question. 21251 <SOURCE>FC&P 27, 2: 40-43.</SOURCE>
21252 <ABSTRACT>The specimen shows characters of both Dimorpharaea and Clausastrea. […] It is difficult to draw conclusions for taxonomy. The specimen indicates that the value of [septal] perforations is less important than is commonly believed. If more material becomes available, the creation of a new genus and its assignation to the Clausastraeidae could be necessary. [excerpts from a short note]</ABSTRACT>

21264 <SOURCE>Geobios 31, 6: 725-766.</SOURCE>
21265 <ABSTRACT>In the Urgonian limestones from Provence of Barremian - Early Aptian age, 29 scleractinian species are described, belonging to 14 families and five suborders: Amphiastreina, Rhipidogyrina, Archaeocoeniina, Stylinina et Astreoina. The suborder Stylinina Alloiteau, 1952, is emended. Twenty genera are recognized among with two new: Saltocyathus and Rhipidomeandra (Rhipidogyrina). Among the 29 species identified, six are new: Donacosmia massaliensis, Paraclausastrea valclusensis, P. pulchra, Diploastraea crassicostrata. Two species belong to the new genera (Saltocyathus urgonensis, Rhipidomeandra bugrovae). On a European scale this fauna tends to characterize the Barremian - Early Aptian interval and shows a strong affinity with the Carpathian fauna even if some of the species are also found in other regions. 21277 <SOURCE>Revista Española de Paleontología, no extraordinario 9 [homenaje al Prof. J. Truyols]: 143-159.</SOURCE>
21278 <ABSTRACT>Los depósitos santonienses (Cretácico Superior) de la plataforma carbonatada de Sant Corneli, en la unidad central surpirenaica contienen, además de rudistas, corales diversos y abundantes. Presentamos los resultados del estudio taxonómico de la fauna de corales escleractinios de la unidad de rudistas y corales de la sección de Sant Martí de Vilanova, en el flanco norte del anticlinal de Sant Corneli cerca de Tremp. Se han descrito 21 especies de 16 géneros y 11 familias diferentes; 5 de las especies se dejaron en nomenclatura abierta. La gran mayoría de las especies reconocidas se encuentran y fueron originariamente descritas en el Cretácico Superior del Grupo Gosau y depósitos afines en los Alpes calcáreos. En este trabajo, las especies han sido identificadas siguiendo un análisis taxonómico clásico, como primer paso a una revisión profunda de la taxonomía de los corales escleractinios del Cretácico Superior. - 21290 <SOURCE>Bulletin of the Tohoku University Museum 1 [Proceedings of the 8th International Symposium on Fossil Cnidaria and Porifera]: 96-113.</SOURCE>
- 21291 <ABSTRACT>A palaeoecological study of a significant number of Lower Cretaceous (Barremian and Aptian) coral bearing sequences in southern France has permitted the classification of coral bearing units according to their litho and biofacies. Schematic depositional models have been produced, and major developmental controls of the coral communities elucidated. Three main types of coral bearing unit and one associated facies are recognized, based principally upon sedimentological criteria. Sub divisions of these groups are determined by the nature of the coral fabric and fauna. The classification scheme comprises: (1a) biostromal units developed within pure carbonate facies and typified by tabulo lenticular coral colony morphotypes; (1b) a biostrome developed within pure carbonate facies, characterized by lamellar to tabulo lenticular colonies; (2a) biostromal units developed within mixed carbonate siliciclastic facies, dominated by lamellar and tabulo lenticular colonies; (2b) biostromal units developed within mixed carbonate / siliciclastic facies, dominated by phaceloid colony morphotypes; (3) lenticular units developed in relatively pure carbonate facies with evidence for early cementation and dominated by lamellar colonies; and (4) coral gravels comprising numerous rounded coral fragments associated with type 1a units. Unit types 1,2 and 3 developed under different ranges of environmental conditions, with type 4 units the associated facies fitting into the type 1 depositional model. Important abiotic factors controlling development of the coral communities were: light intensity, degree of siliciclastic input and sedimentation rate. In contrast to many shallow marine depositional systems associated with zooxanthellate corals, hydrodynamic energy was not an important control on community development. 21316 <SOURCE>Berliner geowissenschaftliche Abhandlungen E18: 3-75.</SOURCE>
21317 <ABSTRACT>A coral-rudist-association is described from the Lower Cretaceous (Lower Aptian) of Greece. The assemblage was found in limestone-olistoliths and ophiolitic conglomerates redeposited in early Tertiary flysch-type deposits of the Parnassus platform near Delphi-Arachowa. The coral fauna is extremely rich in species; 63 coral species in 43 genera are described of which three are new: Pseudomyriophyllia turnsekae, Amphiaulastraea keuppi, Carolastraea graeca.</ABSTRACT>

21329 <SOURCE>Revue de Paléobiologie 23, 1: 313-353.</SOURCE>
21330 <ABSTRACT>We have described 16 species of rudists, 14 species of porifères and 3 species of coral from the Santonian of mount Ptoon in northern Beotia (central Greece). Although this fauna is known in the eastern paleobioprovince, a little endemism has been observed. Two new species of rudists are created: Agriopleura mitzopoulei n.sp. and Agriopleura liatsikaei n.sp. One species of rudistes Praelapeirousia n.sp. and three of porifères Phyllodermia n.sp., Aphrocallistes n.sp. and Coscinopora n.sp. have been remained in open nomenclature.</ABSTRACT>

21343 <ABSTRACT>The neorhipidacanth skeleton microstructure of Cretaceous specimens identified as genera Aulastraeopora Prever, 1909 and Preverastraea Beauvais, 1976 of the family Aulastraeoporidae Alloiteau, 1957, indicate that their proper systematic position is within the suborder Rhipidogyrina Roniewicz, 1976. The microstructure of Albian-Cenomanian aulastraeoporidae corals from the Parnassos-Ghiona Region, Central Greece, is presented here.</ABSTRACT>

21368 <SOURCE>Geobios 27, 4: 433-448. [in French]</SOURCE>
21369 <ABSTRACT>From the Barremian-Early Aptian platform carbonates (Urgonian facies s.l.) from Provence, seven species of hydnochoroid Scleractinia are described. They belong to genera Eohydnochora and Felixigyra (Faviidae) and Hydnochoromeandraraea (Microsolenidae). Two species are new. These taxa are original features of the Provence fauna. Hydnochoromeandraraea shows a restricted palaeobiogeographic distribution, the Felixigyra-Eohydnochora group has a wider one (Eurasia-East Africa and America).</ABSTRACT>

21380 <TITLE>Lower Cretaceous Microsolenina (Scleractinia) from Provence (southern France).</TITLE>
21381 <SOURCE>Annales Societatis Geologorum Poloniae 79, 2: 97-140. <http://www.asgp.pl/></SOURCE>
21382 <ABSTRACT>In the Lower Cretaceous (Urgonian) limestones of the Provence region (South France) shallow-water scleractinian corals are very common. This paper concentrates on corals from the suborder Microsolenina. They represent 34 taxa (including 5 new species) belonging to 14 genera from two families: Microsolenidae and Latomeandridae. This coral assemblage is representative for the late Early Cretaceous Tethyan realm but also shows some endemism. Its characteristic feature is the abundance of hydnochoroid specimens from the genus Hydnochoromeandraraea Morycowa. The Barremian-Early Aptian age of the studied corals is based on foraminifera (mainly orbitolinids), dasycladale algae and rudists, and agrees with that of the whole studied coral fauna. 21393 <TITLE>Albian corals from the Subpelagonian zone of Central Greece (Agrostylia, Parnassos Region).</TITLE>
21394 <SOURCE>Annales Societatis Geologorum Poloniae 72: 1-65.</SOURCE>
21395 <ABSTRACT>Shallow-water scleractinian corals from Cretaceous allochthonous sediments of the Subpelagonian Zone in Agrostylia (Parnassos region, Central Greece) represent 47 taxa belonging to 35 genera, 15 families and 8 suborders; of these 3 new genera and 9 new species are described. Among these taxa, 5 were identified only at the generic level. One octocorallian species has also been identified. This coral assemblage is representative for late Early Cretaceous Tethyan realm but also shows some endemism. A characteristic feature of this scleractinian coral assemblage is the abundance of specimens from the suborder Rhipidogyrina. The Albian age of the corals discussed is indicated by the whole studied coral fauna, associated foraminifers, calpionellids and calcareous dinoflagellates.</ABSTRACT>

21407 <SOURCE>Acta Palaeontologica Polonica 16, 1-2; 149 pp.</SOURCE>
21408 <ABSTRACT>Sont étudiés les Polypiers provenant des dépôts fossilifères marneux et grés-marneux de l'Aptien inférieur de la région de Rarau dans les Carpathes Orientales roumaines. Les Polypiers sont trouvés in situ, souvent aussi en position de vie. Ce sont, en général, des formes coloniales, petites, le plus souvent massives, plus rarement lamellaires ou branchues à rameaux courts et épais. On a constaté 54 espèces (21 déjà connues, 4 déterminées approximativement (aff.), 18 espèces et 6 sous-espèces nouvelles, et 9 formes spécifiquement indéterminables, attribuables à 8 genres différents), réparties en 38 genres (4 genres et 1 sous-genre nouveaux dont un incertae sedis) et 18 familles, dont 17 représentent 5 sous-ordres des Hexacorallia et 1 famille appartient aux Octocorallia. L'assemblage de Coraux étudiés indique l'Aptien inférieur. Le bon état de conservation des Polypiers a permis d'étudier leur microstructure histologique. Les Coraux et les organismes qui les accompagnent suggèrent un milieu marin peu profond, un peu éloigné du rivage, agité, tropical ou subtropical, et une sédimentation assez intense. Les Coraux y formaient probablement des touffes.</ABSTRACT>

21433 <SOURCE>Bulletin du B.R.G.M. (2e sér.), section I, 3/1974: 107-151.</SOURCE>
21434 <ABSTRACT>Les formations calcaires à Rudistes du Crétacé supérieur provençal (Basse Provence) et rhodanien (Basse Vallée du Rhône) ont fait l'objet d'une étude détaillée: paléontologique, stratigraphique, sédimentologique et paléogéographique. On précise tout d'abord leur extension stratigraphique (Albien supérieur à Sénonien inférieur) et leurs caractères paléontologiques (concernant Rudistes et Foraminifères notamment). Les différentes formations sont ensuite décrites sur le plan de la Paléoécologie et de la Sédimentologie et on envisage les phénomènes paléogéographiques qui ont présidé à leur établissement, leur développement et leur disparition au cours du temps (pulsations de la sédimentation terrigène et tectonique). Ces observations conduisent l'auteur à exposer ses conceptions sur l'évolution paléogéographique de la Basse Provence au Crétacé supérieur et sur la notion de formation à Rudistes.</ABSTRACT>

- relation to depositional environments, Eastern Alps.</TITLE>
- 21511 <SOURCE>Fossil Reefs of Austria [W. Piller & B. Hubmann (eds); Schriftenreihe der Erdwissenschaftlichen Kommissionen (Österreichische Akademie der Wissenschaften)]: ??? vol pp ???</SOURCE>
- 21512 <ABSTRACT>During Cretaceous times, in the area of the future Eastern Alps, bioconstructions with corals flourished in pure carbonate and mixed clastic-carbonate environments, each with a distinct coral assemblage. In the early Aptian, on the Helvetic carbonate shelf, coral-sponge biostromes and mounds with a coral assemblage accumulated that is diversified with respect to corallite size, growth forms, polyp integration and taxa. These assemblages grew in clear, well-lit waters of moderate energy. Episodic, destructive high-energy events kept the assemblage at diversification level. The coral fauna is similar to faunas from other locations along the northern, European margin of Neo-Tethys .In the Austroalpine domain, subsequent to a phase of nappe stacking and emergence, upon middle Turonian to early Campanian transgression, deposition in mixed siliciclastic-carbonate environments prevailed. The resulting succession, the Gosau Group, contains abundant corals in a pure coral buildup, in coral/rudist mounds, and in coral-rudist level-bottoms. The corals grew under episodic stress from sediment-nutrient input. Widespread red algal encrustation indicates transient takeover of macroalgae. In mounds and level-bottoms, the coral assemblage records sedimentation and lowered light incidence by prevalence of taxa with large polyparia of plocoid, thamnasterioid orcerioid integration, and of (sub)hemispherical, foliose-lamellar and pedestal-shaped growth form; these features aid in sediment removal and/or maximize light catchment. Coral diversity ranges from 16 species in a pure coral buildup to 29 in coral-rudist mounds, and peaks at 36 species in level-bottoms within "coral marls"; with abundant, diverse solitary forms. Each coral assemblage is dominated by a few "ubiquists". The coral fauna shares species with faunas mainly from France, Spain and Slovenia, but to a part was endemic at least to the area of the future Eastern Alps. The coral-dominated assemblages of the Gosau Group highlight that corals can grow under low to moderately high, medium to long-term terrestrial input of siliciclastics and particulate organic matter. Fossil coral assemblages subject to sediment/nutrient stress show a range of geologically reconcilable features closely similar to Holocene "turbid-water reefs".

21563 <SOURCE>Boletin de la Real Sociedad Espanola de Historia Natural, Seccion Geologica 92, 1/4: 241-247.</SOURCE>
21564 <ABSTRACT>Sediments of Upper Aptian age are located in the central Catalanian Pyrenees. Investigations were based on the associations of corals and rudists that evolved on a carbonate ramp (Read 1985). These bioconstructions were basically controlled by local influences, rather than by global processes. * The associations of corals and rudists show a clear distribution in the middle to upper parts of the ramp. Corals occur in the middle part of the inner ramp in a highly diverse species assemblage. Rudists grow in the shallowest part of the inner ramp, in parts of the transition with rapid changes in sedimentation, corals and rudists form a mixed assemblage.</ABSTRACT>

21575 <TITLE>Vestiges of atoll-like formations in the Lower Cretaceous of the Mecsek Mountains, Hungary.</TITLE>
21576 <SOURCE>Cretaceous Research 17: 419-442.</SOURCE>
21577 <ABSTRACT>Macro- and microfossils and microfacies of a few Lower Cretaceous sections in the Mecsek Mountains have been studied. Twenty five species of corals are reported for the time from the Hungarian Cretaceous. Fossils derived from the carbonate platform are often found together with those of pelagic origin and monomictic volcanoclastics, indicating a special sedimentary environment. Based on this study the following model is proposed for the Early Cretaceous geological history of the Mecsek Mountains: instead of overall uplift and erosion giant basalt volcanoes grew above sea level until the Valanginian, whilst bathyal conditions were preserved between them. The volcanoes were bordered by gravel beaches, then sandy and silty lagoons, and the edges of submarine slopes were crowned by atoll-type build-ups. Fossils and rocks of different environments were transported down the slopes of the volcanoes and mixed. As a result of widespread erosion during the Late Cretaceous or Palaeogene only the basal parts of a few volcanoes are preserved.</ABSTRACT>

21667 <SOURCE>Cretaceous Research 18, 5: 713-729.</SOURCE>
21668 <ABSTRACT>The biostratigraphy of platform carbonates outcropping in the Polish Tatra Mountains is reappraised after a study of three sections located in the autochthonous (including the wysoka Turnia type section for Urgonian limestones) and allochthonous tectonic units. Age assignments are mainly based on calcareous algae, benthic foraminifera and rudists. Heterochrony of coral-rudist facies and their associated bioclastic and orbitolinid facies shows that the platform development and demise occurred at different times in different places. Regional tectonic processes are recognized as the dominant factors of these phenomena. The majority of foraminifera as well as rudists are considered cosmopolitan whereas some dasyclads could be potential palaeobiogeographic markers of the Preapulian Domain. 21720 <ABSTRACT>An integrated sedimentological, magnetostratigraphic, and paleontological study of the Vallcebre section (south eastern Pyrenees, Spain) is carried out in order to define and portray the transition from the Cretaceous to the Tertiary in a continental setting. A robust magnetostratigraphy is correlated to the standard polarity scale in light of known biochronological constraints (charophyte, marine invertebrates, eggshells and other dinosaur remains). Our results show that this section is among the thickest stratigraphic records for the continental Maastrichtian in the Old world. Sedimentology indicates a progressive regression from marine through lagoonal to entirely continental environments. The section is dominated by mudstones deposited under low energy conditions. Exceptionally, a basin-wide regression maximum is recorded some time before the Cretaceous-Tertiary boundary (K/T). This regression maximum is marked by the input of coarse-grained (alluvial) sediments that record a dramatic change in the landscape (quiet mud plains changed to sandy floodplains deposited by high-energy currents). After a period of renewed quiescence following the regression maximum, a Cenozoic flooding took place. Such terminal Cretaceous sequence of events has been recorded in shorter sections in several other basins from southwestern Europe. This energetic sediment input suggests that some time before the K/T event, a sudden paleoenvironmental reorganization took place in the continental basins of south western Europe.</ABSTRACT>

21731 <TITLE>Development of Cretaceous and Paleogene Reef Communities in the Alpine-Mediterranean Realm - Selected Case Studies.</TITLE>
21732 <SOURCE>Goettinger Arbeiten zur Geologie und Palaeontologie, Special Volume 2 [Reitner J., Neuwiller F. & Gunke] F. (eds): Global and Regional Controls on Biogenic Sedimentation I. Reef Evolution]: pp ???</SOURCE>
21733 <ABSTRACT>The studies of selected Cretaceous and Paleogene bioconstructions of the Alpine-Mediterranean realm show a dominance of simple and complex dendriform rudist biostromes since Albian times,

especially mono- and paucispecific monopleurid, caprinid and radiolitid biostromes until the Turonian, radiolitid / hippuritid biostromes in the Late Cretaceous. They occurred in internal as well as external carbonate platform areas, sometimes in open subtidal environments. Rare rudist bioherms are limited to transgressive sequences. Massive-nodular coral-stromatoporoid-dominant bioherms and biostromes of outer and internal platform and carbonate ramp areas are characteristic for the Valanginian-Aptian time interval. Rudist-dominated reef mounds can be found frequently in Aptian-Albian and Coniacian-Campanian sequences. In the Paleogene corallinacean-dominated coral bioconstructions are numerous. Mainly tectonically controlled regional sealevel changes directed the reef growth in the Alpine realm whereas high-frequency sealevel fluctuations were responsible for the development of most of the Mediterranean platform-based bioconstructions. </ABSTRACT>

 21744 <TITLE>Austrian scleractinian corals from the K/T-boundary to the Miocene.</TITLE>
 21745 <SOURCE>Berichte des Instituts für Erdwissenschaften Karl-Franzens-Universität Graz 9: 63-66.</SOURCE>
 21746 <ABSTRACT>This is the first review and compilation of Austrian scleractinian corals from the K/T-boundary to the Miocene. The Austrian corals of the K/T-boundary (here defined as the period MiddleCampanian-Upper Paleocene) show closest affinities to forms that are typical of the upperCretaceous, especially taxa of the Turonian-Lower Campanian strata of the Gosau Group. A firstmajor transition in the faunal composition took place during the late Paleocene. When the 'typicalCretaceous forms' (e.g., Heterocoenia, Paraplacocoenia, Calamophylliopsis) disappeared and thefirst species of modern genera (e.g., Astreopora, Acropora, Goniastrea, Alveopora) appeared; allspecies of the latter vanished during the Eocene together with all genera which are characteristic ofthe Eocene-Oligocene period (Stylocoenia and Pattalophyllia) in other geographic areas. With thebeginning of the Miocene another significant change of the Austrian coral fauna was observed due to the occurrence of both numerous solitary taxa (e.g., Caryophyllia, Deltocyathus, Discotrochus, and Flabellum) as well as colonial hermatypic genera (e.g., Porites and Tarbellastraea).</ABSTRACT>

 21757 <TITLE>Coral Fauna and Facies of the Oligocene Fringing Reef near Cairo Montenotte (Liguria, Northern Italy).</TITLE>
 21758 <SOURCE>Facies 13: 175-226.</SOURCE>
 21759 <ABSTRACT>1 km south of Cairo Montenotte, a small fringing reef in limestone facies was formed in terrigenous sediments during the Oligocene transgression. It has a thickness of 40-60m. The lower part consists of terrigenous-influenced to pure limestone and contains

isolated corals, or concentrations of massive corals in coral mounds. The upper part is principally characterized by a dense framework of massive, sometimes branching corals. The coral fauna consists of 27 species, dominated by *Goniopora ramosa* or *Actinacis rollei*. 23 species were found on the reef front, none of which predominate. The reef tapers off in various directions in small units of reef limestone and biocalcarenite. The coral fauna and the reef facies are studied in detail. The vertical development of the coral limestones and lateral variations in the reef core, as well as the distal facies, are described. The corals are identified and the general character of corals and reef framework investigated. Communities and palaeoecological relations are described. </ABSTRACT>

21770 <TITLE>Palaeoecological significance of coral-encrusting foraminiferan associations: A case-study from the Upper Eocene of northern Italy. </TITLE>

21771 <SOURCE>Acta Palaeontologica Polonica 48, 2: 279-292.</SOURCE>

21772 <ABSTRACT>Encrusting foraminiferans, although representing an important component of the so-called cryptic assemblages in both modern and ancient reef environments, are in general poorly described and little is known as regards their association with corals. In this paper, we describe coral-encrusting foraminiferan associations in the different facies that characterize the shallowing upward parasequences of the Nago Limestone (Upper Eocene, Trentino, northern Italy). From a relatively deep reef slope up to the shallow shelf-edge, corals have been recognized to be encrusted by different types of foraminiferan assemblages that differ on the basis of relative abundance of species, growth form and different type of encrusted coral surface. The succession of encrusting foraminiferan assemblages is interpreted as controlled mainly by light, competition with coralline algae, hydrodynamic energy, and coral growth fabric. </ABSTRACT>

21784 <SOURCE>Rivista Italiana di Paleontologia e Stratigrafia 98, 3: 339-352. </SOURCE>

21785 <ABSTRACT>The Castalgomberto Limestone is a 200m thick unit of Early Oligocene age (Rupelian) outcropping in the Eastern Lessini Mountains (Southern Alps of Northern Italy). The internal cyclic organization of this Oligocene unit is described and analyzed on the basis of four selected sections; about thirteen well-bedded grainstone units alternate with marly horizons rich in corals. This peculiar cyclicity is here interpreted as a response to variation in platform hydrodynamics, i.e. to smaller eustatic fluctuations affecting the Lessini Shelf reef-lagoonal complex. During highstand periods, the

shelf was open and relatively deep (20-50 m), and tidal currents and periodic storms were able to distribute bioclastic sands (bars, sand waves and spillovers). During lowstand the shelf was more protected by the occurrence of marginal reefs and was colonized by patches of poritid corals, mainly branching. Moreover, the largely exposed northern areas supplied fine detritus to the shelf itself. </ABSTRACT>

21796 <TITLE>Coral reef diagenesis records pore-fluid evolution and paleohydrology of a siliciclastic basin margin succession (Eocene South Pyrenean foreland basin, northeastern Spain).</TITLE>

21797 <SOURCE>Bulletin geological Society of America 111, 3: 395-411.</SOURCE>

21798 <ABSTRACT>An integrated field, petrographic, and geochemical study has determined the fluid-rock interaction history in part of an Eocene reef complex on the margins of the siliciclastic-dominated Catalan sector of the South Pyrenean foreland basin. Results show that at least four distinct fluid systems influenced the basin margin, and demonstrate the sensitivity of reef rocks as paleohydrological archives in siliciclastic environments. The earliest calcite cements precipitated from meteoric waters at shallow burial depths, and mineralogical stabilization of reef carbonate was mostly completed during this episode. Textural and isotopic trends typical of paleoexposure surfaces are lacking, and trace elements results suggest that meteoric waters were transmitted laterally and/or upward into the reef via delta-lobe sandstone aquifers. The distribution of late cements is highly variable and fracture-fed, demonstrating the importance of deformation in controlling fluid flow subsequent to reef lithification. Isotopic and elemental compositions of burial calcites, plus their paragenetic association with barite and dolomite, show that fluids of marine parentage were expelled from compacting.</ABSTRACT>

21810 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 261-264.</SOURCE>

21811 <ABSTRACT>A well-exposed Middle Chattian fringing reef complex outcropping for at least 40 km along the coastline of the Salento Peninsula (Southern Italy) is here described, contributing to a better knowledge of the evolution of Oligocene reefs in Italy and in the Mediterranean area. The fringing reef complex is represented by the Castro Limestone, an unconformity-bounded depositional sequence mantling a tectonically deformed "falaise" of Cretaceous-Eocene rocks. Stratigraphic and sedimentological features, together with paleontological characters, allow recognition of a virtually complete

- range of reef tract environments. Different geomorphic zones and associated coral facies, from back reef to fore reef, are here described.

21835 <TITLE>The coral fauna of Vitigliano: qualitative and quantitative analysis in a back reef environment (Castro Limestone, Late Oligocene, Salento Peninsula, Southern Italy).</TITLE>
21836 <SOURCE>Bolletino della Societa Paleontologica Italiana 33, 2: 171-181.</SOURCE>
21837 <ABSTRACT>The Castro Limestone, Middle Chattian in age, consists of various reef facies and has been described as a fringing reef complex developed along the Cretaceous-Eocene rocky coast of the Salento Peninsula. The reef facies outcropping near Vitigliano and the associated coral fauna, which have been previously interpreted to be part of a back reef subenvironment, are here defined both qualitatively and quantitatively. Together with palaeontological and sedimentological observations, three main quantitative methods have been used for the characterization of the back reef facies: 1) count of coral colonies on a subvertical measured surface, 2) line-transect, 3) quadrat. The composition of the coral was identified in the field mainly at the generic level and abundance of different genera has been analyzed. The results obtained from the various quantitative methods were compared and discussed. Moreover, the coral density has been quantified from both linear and area measurements and has been evaluated to be around 20%. However, corals occur as scattered colonies and do not form a true framework.</ABSTRACT>

- 21876 <ABSTRACT>The terrigenous and carbonate sediments of the transgressive Oligocene cycle of the Tertiary Piedmont Basin outcropping in the area of Valzemola (Savona, western Liguria, Northwest Italy) and which are referable to the Molare Formation are analysed. The terrigenous sequence, represented by breccias, conglomerates and sandstones, overlies with an angular unconformity dolomitic or calcareous-dolomitic lithologies referable to the San Pietro dei Monti Dolomite Formation. These sequences are locally characterized by rich associations of coralline algae and corals, which by providing a stable substrate allowed the development of a true reef buildup. Subsequently the bioherm was suffocated by fluvial sandstone and conglomerate. This may be associated with an intensification in the amount of terrigenous material being brought into the basin. A progressive shallowing continues until the introduction of conditions suitable for calcareous deposition in an intertidal or supratidal environment. The analysis of this reef deposit was carried out by examining seven stratigraphic

sections. The paleoecological study of the coral fauna and the algal assemblage, the latter characterized by the significant presence either of the genus *Lithophyllum*, or of *Lithothamnion*, allowed some hypothesis on the environmental conditions which characterized this sector during the Late Oligocene. Nine different facies could be shown, from those seven directly connected to the reef and two to nearshore environments proving a regressive phase. Facies I: conglomeratic-sandstone representing a stage of colonization in a dominantly terrigenous environment. Facies II: coral framestone, representing a stage of diversification (an inner reef front; near to the reef crest;). Facies III: coral bafflestone representing a colonization stage in an inner reef slope;. Facies IV: coral bindstone representing a stage of domination in a reef crest; environment. Facies V: coral bindstone alternating with floatstone, gives evidence of a colonization stage in a carbonate environment. Facies VI: coral and algae floatstone, representing a facies of accumulated reef debris. Facies VII: coral rudstone, representing an accumulation facies comparable with that of the rubble; pavement zone; of the back reef. Facies VIII: conglomerates and sands of a shallow marine environment, represent a regressive sequence. Facies IX: massive limestones with undulated-zoned structures, rhizoliths, calcite veins and pisoliths, evidence of an intertidal or supratidal environment.

 21901 <SOURCE>Senckenbergiana lethaea 68, 5/6: 321-335. [in German, with English summary]</SOURCE>
 21902 <ABSTRACT>New material of *Septachaetetes eocenus* Rios et Almela 1944 (Demospongea) from the Eocene of Samitier (Prov Huesca, Spanish Pyrenees) is being studied. The primary and diagenetic (lamellar) microstructures of the wall as well as the general morphology of the tubes of this species are identical with the corresponding characters of *Acanthochaetetes seunesi* Fischer 1970 (Albian - Cenomanian) and of the Recent Pacific *acanthochaetetids*. Therefore, *Acanthochaetetes* Fischer is regarded as a junior synonym of *Septachaetetes*. The Eocene genus *Diplochaetetes weissermei* 1913 belongs to the *Polychaeta*

- sedentaria. Symbiotic serpulids within the skeleton of septachaetetes eocenus are described.</ABSTRACT>

- 21940 <SOURCE>Courier Forschungsinstitut Senckenberg 239: 83-127.</SOURCE>
- 21941 <ABSTRACT>The Mesohellenic Basin of northwestern Greece is a molasse basin with thick sequences of predominantly terrigenous sedimentary rocks. Nevertheless, coral growth occurred during short periods in the Early and Late Oligocene: (1) a coral reef formed during the initial phase of basin subsidence on a palaeotopographic high, and (2) during a regressive stage in the Late Oligocene when shallow sublittoral conditions prevailed. The fauna of the coral reef is highly diverse (31 species / 25 genera) and is composed of massive dome-shaped, bulbous, branching, foliaceous, and solitary species. Like other Oligocene coral faunas from the central Mediterranean Tethys, the coral fauna is rich in members of the family Faviidae (Caulastraea, Favites, Hydnothra, Leptoria, Montastraea) and Agariciidae (Cyathoseris, Leptoseris, Pavona). The second coral horizon is dominated by allochthonous branches

of Acropora, massive growing colonies are associated and partly use these accumulations as substrate. These accumulations are interpreted as former densely growing thickets of lagoonal environments which were destroyed by storm events. Again, the most important genera are found in the family Faviidae (Agathiphyllia, Antiguastrea, Hydnohpora, Montastraea, Tarbellastraea). This study presents for the first time a comprehensive taxonomic study of Early and Late Oligocene corals from Greece. It is the first time that an Acropora dominated assemblage is reported from sedimentary sequences as old as the Late Oligocene. This study concentrates on the taxonomic description of the coral fauna.

21965 <TITLE>Diversity, composition and structure of Late Eocene shelf-edge coral associations (Nago Limestone, Northern Italy).</TITLE>

21966 <SOURCE>Facies 39, 1: 203-225.</SOURCE>

21967 <ABSTRACT>During the Late Eocene, shelf-edge patch reefs developed on the western margin of the Lessini Shelf. The coral fauna, studied in the Nago Limestone type locality, is described and interpreted for the first time, and provides further data for better understanding of the generally poorly known Eocene reef communities. * Facies analysis was carried out across the shallowing upward succession that characterizes the well exposed type-section of the Nago Limestone. Four distinct facies are identified and a detailed qualitative-quantitative investigation has been applied to the coral-bearing facies in particular, in order to describe and quantify the distribution and palaeoecological zonation of corals. * By a comparison of sedimentological and palaeoecological data, it is possible to reconstruct a depositional model of the Nago Limestone at its type locality. In particular, the palaeoecological study clearly reveals that corals change with depth in taxonomic composition, in percentage and proportion within the framework and in growth form, allowing the definition of a relative depth coral zonation. * Three coral associations are recognized from the base to the top of the shallowing upward sequence. These differ from each other in the relative abundance of main reefbuilders, in the growth form exhibited by corals in growth position and in the density of the reef framework. These variations are interpreted as responses to major environmental controls which prevailed during the deposition of the different facies (mainly light intensity and hydrodynamic energy). * The coral species *Actinacis rollei* Reuss is the most abundant and ubiquitous coral of the Nago Limestone.

Its adaptation to low-light levels is described here for the first time, confirming the high plasticity of this important Paleogene reef-builder. * The results of the present study are finally compared with data from other Middle-Late Eocene European reef sites and some common features are inferred. 21978 <TITLE>Autecological significance of growth form in the scleractinian *Actinacis rollei* Reuss (Oligocene, Lessini Mountains, Northern Italy).</TITLE>

21979 <SOURCE>Bolletino della Societa Paleontologica Italiana, Spec. vol. 3: 31-43.</SOURCE>

21980 <ABSTRACT>The scleractinian coral *Actinacis* is an important component of reef communities from the Oligocene Lessini Shelf of Northern Italy. The coral-rich Castalgomberto Limestone of Rupelian age contains abundant *Actinacis* that occur as massive-laminar colonies or thin to thickly branched thickets. These two growth forms respectively dominate the coral assemblages in the alternating biocalcarenic and marly facies that compose the Castalgomberto Limestone. In the present study, we have used a combination of discriminant analysis and principal component analysis of corallite measurements to show that these two distinct colony morphs cannot be distinguished on the basis of corallite characteristics. Thus, the two growth forms represent a single species, *A. rollei*, with a colony shape that varied as an autoecological response to the differing environmental conditions that prevailed during deposition of the two facies. The massive to laminar growth form probably developed as a response to the unstable coarser-grained substrate and higher wave energies represented by the biocalcarenic facies. The branched form is most probably adapted for coping with the large volume of fine grained sediment deposited in the quiet water, marly lagoonal environments of the Oligocene Lessini Shelf. Similar coral morphologies are found among modern corals in analogous reefal environments, although few living coral species possess a range of shape variation comparable to that of *A. rollei*. This plasticity of colony form could be partly responsible for *A. rollei* dominance in many Oligocene reef communities.</ABSTRACT>

22018 <SOURCE>Geobios 32, 6: 805-813.</SOURCE>
22019 <ABSTRACT>The study of numerous specimens of one species of scleractinian coral, outcropped within two Chattian (Upper Oligocene) localities of southern Aquitaine, showed an original set of morphological features leading to the definition of a new dendrophylliid genus, Cahuzacopsammia. The description of this form, made easy thanks to the very good preservation of the material, contains an approach of its variability and some aspects concerning its way of growth, by the mean of the study of this abundant population. Cahuzacopsammia seems to be the first-recorded meandroid Dendrophylliidae. This coral family contained so far several plococorals to plococorals-meandroid genera, as well as 3 flabellum-meandroid ones. This taxon is encountered in reef sediments, rich in macrofauna and large benthic foraminifera (miogypsines, Nummulitidae, lepidocyclines), that can be dated from the upper part of Chattian (about 24,5 My). The associated coral fauna is very diversified (85 species for Abesse outcrop and 52 for Estoti, mainly hermatypic ones). [original abstract]</ABSTRACT>

22057 <SOURCE>Facies 26: 145-166.</SOURCE>
22058 <ABSTRACT>The coastline of the Salento Peninsula (Apulia region, Southern Italy) is characterized by a rocky shore with spectacular cliffs where the investigated fringing reef complex, the so called Castro Limestone, spectacularly outcrops for at least 40km. As reconstructed from several measured sections, the Castro Limestone, which is Middle Chattian in age from our own data, disconformably mantles a tectonically deformed falaise of Cretaceous-Eocene rocks and is overlain by a remarkable erosional surface characterized by a very peculiar rhodolite rudstone. The Castro Limestone unit can be considered as a classic unconformity bounded depositional sequence representing, most probably, a shelf margin prograding complex, related to the major Middle Oligocene sea level lowstand. Stratigraphic and sedimentologic features, together with paleontological characters, allow recognition of a virtually complete range of reef environment across the reef profile. Several geomorphic zones and associated facies are described, from the most landward reef area ("back reef";) across the reef flat and reef front downward to the fore reef slope, contributing to better knowledge of the evolution of Oligocene reefs and reef communities in Italy and in the Mediterranean area.</ABSTRACT>

22070 <SOURCE>Muenchner Geowiss. Abh. A23: 1-166.</SOURCE>
22071 <ABSTRACT>Litho-, bio-, as well as paleocological analysis of two Lower Priobanian (Upper Eocene) reef complexes (Eisenrichterstein near Hallthurn, Northern Calcareous Alps and Kirchberg near Neubeuern, Helveticum) enable depositional reconstruction models to be established. Based on these analyses, significant deviation from previous models is suggested. The Eisenrichter complex, whose tectonic control has for the first time identified, constitutes rocks derived from a beach area (conglomerates), a lagoon (calcarenes), and a reef

complex (coral limestones and associated rocks). The reef complex is characterized by distinctive bedding and the absence of a reef core. Consequently, the Eisenrichterstein complex can be regarded as a carbonate ramp. The coral limestones of Kirchberg are olistholithes. The Kirchberg quarry may, therefore, be considered as an olisthostrome exposure which is genetically related to the turbiditic Lithothamnium limestones of the Rohrdorf quarry. The geology of the southern margin of the Intrahelvetic High, from which the Kirchberg olisthostrome is derived, can be updated, due to data gathered from the Kirchberg region and the accompanying olistholithes. The depositional model depicts a shelf rimmed with algal bioconstructions. The qualitative determination of fauna provided evidence of many different taxa (foraminifera, bivalves, gastropods, corals, bryozoans and echinoderms), which are treated in the second part. The corals *Stylocoenia polypostyla* n.sp., *Astreopora schedakena* n.sp., *Ewaldocoenia pollaplasia* n.sp., *Cyathoseris krepidoblasta* n.sp. and the gastropod *Turritella caecisutulis* n.sp. have been newly described. </ABSTRACT>

22084 <ABSTRACT>The Maiella platform provides an example of the innovation and evolution of coral-algal reefs during the Paleocene. After the disappearance of rudist-dominated reefs around the Cretaceous / Tertiary (K/T) boundary, coral-algal reefs grew along the platform margin and top during two subsequent sealevel highstands in the Danian-Early Thanetian and Late Thanetian. The Danian-Early Thanetian reef communities are more diverse, and the constructional types more evolved than those previously known from this time. The Danian-Early Thanetian coral association differs from the Upper Thanetian association and from upper Cretaceous coral faunas, indicating that it represents a distinct evolutionary phase. Repeated emergence of the Danian-Early Thanetian reefs resulted in a complex diagenetic history. All these Paleocene reefs were displaced by gravitative redeposition.</ABSTRACT>

22095 <TITLE>Paleocene Reefs on the Maiella Platform Margin, Italy: An Example of the Effects of the Cretaceous / Tertiary Boundary Events on Reefs and Carbonate Platforms.</TITLE>
22096 <SOURCE>Facies 36, 1: 123-140.</SOURCE>
22097 <ABSTRACT>Reef facies, reef types and their biotic associations in the Maiella platform margin (central Italy) provide qualitative evidence

for a significant reef decline across the Cretaceous / Tertiary (K/T) boundary, and indicate two phases of reef recovery during the Paleocene. Rudists dominated the reef community until the latest Cretaceous. A significant sea-level fall around the time of the K/T boundary is documented by a truncation surface associated with emersion. During sea-level highstands in the Danian to Early Thanetian and, more extensively, during the Late Thanetian, coral-algal patch-reefs grew along the platform margin and top. Already in the Danian to Early Thanetian, the reef communities were more diverse and the constructional types more evolved than previously known from this time. Differences between the Danian to Early Thanetian coral association, the Late Thanetian association, and Late Cretaceous coral faunas may have ecological or evolutionary causes. Repeated emergence produced a complex diagenetic history in the Danian to Lower Thanetian limestones. All Paleocene reefs were displaced by gravitative redeposition. Coral-algal reefs are less important in the Early to mid Eocene, when alveolinid foraminifera dominated on the Maiella shelf. Reefs on the Maiella platform diversified and attained large sizes in the Late Eocene to Early Oligocene, as known from other Mediterranean platforms. The external controls on the Late Cretaceous to Oligocene evolution and demise of reef communities that are most easily demonstrated with our data are sea level fluctuations and climate change. We propose that the change in reef biota and reef types across the K/T boundary and during the Early Tertiary were important causes of the parallel changes in platform growth style. </ABSTRACT>

 22110 <ABSTRACT>This Guidebook details the first results of the analysis of the relationship between the facies with Larger Foraminifera and Microforaminifera, and facies with corals. Within the latter, the nutrient content of the waters is analysed in terms of the Microforaminifera Communities and the diversity of coralline species. This work was undertaken by Jordi Franques as part of his Degree Thesis "Paleoecologic study of the la Triona Reef (Bartonian - Middle Eocene, Ebro basin - Vie area)" which was recently accepted by the University of Barcelona. These works will be published in greater depth in a forthcoming special edition of the magazine of the Facultat de Geologia (Universitat de Barcelona) and - Institute de Ciencias de la Tierra "Jaime Almera" (Consejo Superior de Investigaciones Cientifica) in Acta Geologica Hispanica.</ABSTRACT>

22122 <SOURCE>Courier Forschungsinstitut Senckenberg 172 [Oekentorp-Kuester P. (ed.) Proceedings of the VI. International Symposium on Fossil Cnidaria and Porifera, vol. 2]: 249-259.</SOURCE>
22123 <ABSTRACT>The La Trona reef tract (middle Eocene) formed on abandoned delta-lobe deposits of the delta complexes related to the northern margin of the South Pyrenean Foreland Basin. Facies architecture and distribution of coral genera allow one to interpret the reef environments and their evolution in space and time. The initiation of reef growth and the first stages of colonisation suggest formation during a sea-level rise, but the main phase of reef growth which brought about seaward progradation of the reef-framework above reef-talus deposits, occurred at stable high-stand sea level conditions.</ABSTRACT>

22136 <ABSTRACT>Shallow mixed siliciclastic-carbonate platforms developed since the Middle Eocene to Lower Oligocene in the Balearic Islands. Coral patches and small patch-reefs developed here in a lagoon environment, not having yet found any evidence of the existence of a barrier-reef in the most distal counterparts. Maximum extent of the reef environment occurred during the Upper Priabonian and Lower Stampian. The study of corals yielded 23 species in 18 genera, most of these are reported for the first time in the Balearic Islands. The new species *Acropora ramosi* is described.</ABSTRACT>

22147 <TITLE>A coral-mollusc (*Goniaraea-Crassatella*) dominated hardground community in a siliciclastic-carbonate sandstone (the Lower Eocene Roda Formation, Southern Pyrenees, Spain).</TITLE>
22148 <SOURCE>Palaios 06: 142-155.</SOURCE>
22149 <ABSTRACT>Provided sufficient time is available, hardground faunas may develop in mixed siliciclastic-carbonate sandy environments. The coral *Goniaraea elegans* and the bivalve *Crassatella depressa* are the dominant members of a Lower Eocene clastic hardground community, which developed on top of a mixed siliciclastic-carbonate sandstone body. Sedimentological data indicate that the sandstone body was formed in a shallow marine, tidally influenced deltaic environment. Hardground formation was initiated by the development of an early carbonate fringe-cement, matrix infiltration and bioturbation. Initially, these processes caused the formation of cemented nodules. When clastic

sedimentation ceased long enough, these nodules accreted into laterally continuous concretionary layers. In a few cases only, a pause in sedimentation lasted long enough for settlement of a typical hardground community. The latter hardgrounds can be easily recognized on the basis of paleontological criteria. This fauna is dominated by a *Goniaraea-Crassatella* assemblage; the associated fauna consists mainly of epifaunal or shallow infaunal species. Sponge boring in *C. depressa* valves has been intense and gives further evidence for a prolonged cessation of sedimentation in this shallow environment. The boulder shape of the hermatypic coral *Goniaraea elegans* is an ecomorph adaptation to slightly turbulent, but shallow and clear marine hard bottom environments.

22160 <TITLE>Paleocene reef sediments from the Maiella carbonate platform, Italy.</TITLE>
22161 <SOURCE>Facies 32: 213-222.</SOURCE>
22162 <ABSTRACT>Upper Cretaceous and Paleocene reef limestones from the Maiella carbonate platform show how reefs evolved during a time of faunal turn-over. Biostratigraphy and facies analysis of the reef limestones reveal the details of reef growth, composition, and age. Rudists disappeared as reef builders from the Maiella platform shortly before the Cretaceous / Tertiary boundary. Small coral-algal reefs became established in the Danian to Late Thanetian. These scleractinian-red algal dominated boundstones and framestones represent two periods of reef sedimentation and the subsequent interruption of reef growth by emersion and erosion, controlled primarily by fluctuations of relative sea-level. The coral-algal reefs evolved as the taxonomic composition of reef organisms changed. The Paleocene reef sediments are preserved as large slide blocks and as boulders redeposited from the shallow-water platform onto the slope during the course of the Paleocene.</ABSTRACT>

22173 <TITLE>Commensalism between a boring mytilid bivalve and a soft bottom coral in the Upper Eocene of Northern Italy.</TITLE>
22174 <SOURCE>Paläontologische Zeitschrift 56, 3/4: 165-175.</SOURCE>
22175 <ABSTRACT>The mytilid bivalve *Botula cordata* (Lamarck) from the Upper Eocene of the Venetian region, northern Italy, bored into live soft bottom corals, which reacted by forming a calcareous interseptal filling around the borehole. A chemical etching mechanism is inferred from the presence of etch marks on the borehole walls. The association with free-living corals capable of counteracting burial by sedimentation or accidental overturning enhanced the survival potential of the bivalve on the soft bottoms. Commensalism with soft bottom corals appears to have evolved convergently at least three times within the Mytilidae, but is unknown among other bivalves. [original summary]

22186 <TITLE>Filling a gap: The first occurrences of Epiphaxum (Cnidaria: Helioporacea: Lithotelestidae) in the Eocene, Oligocene and Miocene.</TITLE>
22187 <SOURCE>Palaeontology 51, 1: 241-250.10.1111/j.1475-4983.2007.00744.x</SOURCE>
22188 <ABSTRACT>A new species of the genus Epiphaxum (family Lithotelestidae) is described and illustrated in detail, and compared to other species. Epiphaxum arbuscula sp.nov. has been collected from Upper Eocene (Priabonian), Upper Oligocene (Chattian) and Lower Miocene (Upper Burdigalian) deposits of the Aquitaine Basin, south-west France. Epiphaxum is a poorly documented genus but its fossil record extends back to the Late Cretaceous; it was previously known only from the Paleocene (Danian). Epiphaxum arbuscula differs from all others species of the genus in the form of its colony. In contrast to the creeping colonies of previously known species, it has branched colonies. It is very common at one Upper Oligocene outcrop from which an assemblage with submarine cave remains has been described. A close relationship between the three extant species (two from the Caribbean Sea and one from the Indo-west Pacific region) and the Paleogene species is also noted. These constitute a group that has not undergone any important morphological changes for the last 65 million years. [original abstract]</ABSTRACT>

- 22212 <TITLE>Coral microbiolite environment in a Middle Miocene reef of Hungary.</TITLE>
- 22213 <SOURCE>Palaeogeography, Palaeoclimatology, Palaeoecology 160: 179-191.</SOURCE>
- 22214 <ABSTRACT>The presence of microbial crusts (microbiolites) is reported here for the first time from a Middle Miocene (Badenian) coral reef in Hungary. The succession of initiation and development of the microbial crusts is described in relation to the reef architecture. The main features of the palaeoenvironment are discussed., with focus on the associated invertebrate faunas, mostly corals, molluscs, bryozoans, and crabs. We conclude that the microbial crusts developed under normal marine conditions and were a significant contributor to reef framework development, including strengthening through calcification of the microbial organisms. Microbiolites are anticipated in other Early and Middle Miocene coral reef occurrences of the Mediterranean-Paratethys realm, and to date may have simply escaped positive recognition.</ABSTRACT>

- 22395 <SOURCE>Bollettino della Societa Paleontologica Italiana 36, 1-2: 53-61.</SOURCE>
- 22396 <ABSTRACT>This paper deals with a coral bank interbedded in Pleistocene silty sands which outcrop in the Crati valley (Calabria, Southern Italy). The morphometric analysis of several colonies of *Cladocora caespitosa* (Linnaeus) is based on measurements concerning both the colony and the individual corallites. The significant correlations obtained from a statistical analysis indicate that the regular and unchanged growth of the bioconstructions occurred in quite a dim environment, and a deep infralittoral allocation is also suggested by the associated molluscan fauna. The paleoenvironment suffered a sudden, strong sediment input, correlated to tectonic activity, which caused the burial of the colonies. The re-colonization of the bottom took place while the bathymetric conditions remained unchanged. The definitive burial of the coral bank is marked by a transgressive phase which yielded the deposition of circalittoral clayey sediments. [original abstract]</ABSTRACT>

22459 <TITLE>Deep-water coral banks: an example from the "Calcare di Mendicino" (Upper Miocene, Northern Italy).</TITLE>
22460 <SOURCE>Facies 47, 1: 27-42.</SOURCE>
22461 <ABSTRACT>The "Calcare di Mendicino" is a mixed carbonate-siliciclastic informal unit of Miocene (Late Tortonian-Early Messinian), that crops out extensively in the northwestern part of the Calabria. In the Scannelle quarry near Belsito (Cosenza), four stratigraphic sections were studied to define the sedimentological and paleoecological setting. The carbonate body records the development of a deep-water coral bank characterized by a low-diverse community of azooxanthellate scleractinian (Oculina and Dendrophyllia) and stylasterine hydrozoans colonies. Two main stages of bioconstruction development can be distinguished: a thicket and a bank stage. Among the biostromal dwellers the more common are bryozoans, echinoids, benthic foraminifers, gastropods, and bivalves. A higher content of planktonic foraminifers occur in the thicket stage. The coral bank flourished within the aphotic zone, with deep currents loaded with nutrients and siliciclastic sediments. The upper part of the "Calcare di Mendicino " carbonate body has been affected by a pervasive dolomitization destroying almost completely the sedimentary structures and the biofacies. The lower part, the main object of this paper, preserves the microfacies but it experienced a widespread recrystallization obliterating the primary geochemical characteristics. The diagenetic history, partly hidden, reveals three main stages: primary marine with isopachous fibrous cements, deep burial with cavities infilled by sparry calcite, and meteoric-phreatic with dog-tooth cements.</ABSTRACT>

22472 <TITLE>Distribution and Abundance of Macroborers in an Upper Miocene Reef System, Mallorca, Spain: Implications for Reef Development and Framework Destruction.</TITLE>
22473 <SOURCE>Palaios 11, 1: 40-56.</SOURCE>
22474 <ABSTRACT>The importance of boring organisms within reef environments, as agents of framework destruction, and thus as controls to rates of reef accretion, has been widely recognized. Relatively little, however, is known about variations in the distribution of macroborers (principally sponges, bivalves and worms), within individual reef systems. The Upper Miocene reefs of Mallorca present a unique opportunity in which to assess such distributional variations. Borings are preserved as casts within the molds of former corals, and these trace fossils typically exhibit highly characteristic morphologies. Based on the distribution of different bore morphologies, it has been possible to assess variations in both the distribution and abundance of individual borers, and the intensity of boring activity across the reef system. Different parts of the reef are characterized by different associations of boring organisms, with the highest diversity of borers, and the most intense boring activity, observed within corals from the lagoonal facies. The principal control on distributional patterns appears to have been the morphology and structure of the reef framebuilders. Massive corals are always more extensively bored, and typically contain a higher diversity of boring organisms than branched or platy corals. On a more local scale, variations in sediment accumulation rates, and degree of substrate encrustation appear to have exerted some degree of control. Rates of reef accretion would have been influenced not only by the abundance of different boring organisms in different parts of the reef, but on the response of different framebuilders to boring activity. Platy and branched corals, whilst typically less intensely bored, would have been more vulnerable to the effects of boring, while massive corals, which were often extensively bored, were more capable of surviving such damage. This preservational bias has important implications for interpreting styles and rates of reef accretion.</ABSTRACT>

22485 <TITLE>Reef geometries, erosion surfaces and high-frequency sea-level changes, upper Miocene Reef Complex, Mallorca, Spain.</TITLE>
22486 <SOURCE>Sedimentology 38: 243-269.</SOURCE>
22487 <ABSTRACT>The upper Miocene Reef Complex of Mallorca is a 20km prograding unit which crops out in sea cliffs along the southern side of the island. These vertical and exceptionally clean outcrops permit: (i) identification of different facies (lagoon, reef front, reef slope and open platform) and their geometries and boundaries at different scales, ranging from metre to kilometre, and (ii) construction of a 6-km-long high-resolution cross-section in the direction of reef progradation. This cross-section shows vertical shifts of the reefal facies and erosion surfaces linked to a general progradational pattern that defines the accretional units. Four hierarchical orders of magnitude (1-M to 4-M) of accretional units are identified by

- consideration of the vertical facies shifts and by which erosion surfaces are truncated by other erosion surfaces. All these orders show similar patterns: horizontal beds of lagoonal facies in the upper part (landward), reefal and slope facies with sigmoidal bedding in the central part and open-platform facies with subhorizontal bedding in the lower part (basinwards). The boundaries are erosion surfaces, horizontal over the lagoon facies, dipping basinwards over the reef-front facies and connecting basinwards with their correlative conformities over the reef-slope and open-platform facies. - 22500 <ABSTRACT>The Messinian carbonate platform on the Maltese Island contain a scleractinian coral reefal unit overlying a basal melobesian buildup group. The coral assemblage is constituted by only few genera which display a poorly diversified architecture and growth forms. The buildup community sequence observed all along the platform shows a slightly homogenous evolution and, during the same time, a constant association with rhodophyceae. The corallian reefal unit is overlain by shallow marine sediments containing ooids and stromatolitic levels which correspond to final stage of the Messinian platform history.</ABSTRACT>

- 22526 <ABSTRACT>A peculiar coralg al facies is recognized in the Lviv-Ternopil region, Ukraine, from the northern shores of the Middle Miocene (Badenian) Fore-Carpathian Basin. Its complex structure is dominated by algal buildups composed of interfingering red-algal (lithothamnian) colonies and blue-green-algal crusts, associated locally with numerous hermatypic corals (*Tarbellastraea reussiana*, *Porites vindobonarum prima*), either isolated, or overlapping each other. The holes amidst, and the crevices in, the buildups are filled with coarse bioclastic sediment (shell-grit), burrowed commonly by crustacean decapods (alpheid shrimps). The alpheid burrows, filled with coarser or finer shell-grit, served frequently as taphonomic traps for crustacean decapods (squat lobsters and crabs) and echinoids. Special attention is paid to the activity of rock-boring bivalves (*Jouannetia semicaudata*, *Lithophaga lithophaga*) in coralg al buildups and/or in particular coral colonies, some of which are redeposited, and riddled densely by bivalve borings. Emphasis is given to the environmental significance of alpheid shrimps, the tiered burrows of which are recorded in the Fore-Carpathian Basin for the first time. Crustacean decapods and echinoids are systematically studied. A comparison of the studied coralg al facies with others of the Lviv-Ternopil region, and those from the territory of Poland, indicates their faunistic and biogeographic identity. - 22537 <TITLE>A Holocene coral-algal reef at Mavra Litharia, Gulf of Corinth, Greece: structure, history, and applications in relative sea-level change. </TITLE>
- 22538 <SOURCE>Marine Geology 215, 3-4: 171-192. </SOURCE>
- 22539 <ABSTRACT>A Holocene coral-algal reef at Mavra Litharia, south-central coast of Gulf of Corinth, Greece, is exposed from ca. 2 to 9.3 m above sea level on an uplifting footwall associated with the Eliki Fault. The reef lacks sea-level-critical species but its coralline algal assemblage indicates a ca. 10m water depth. Reef-frame components date from 9280-8730 years BP to 6343-5993 BP, so the reef frame grew between ca 10,000 and 6,000 years BP. The youngest dated shells (1860-305 years BP) from the site are accessory organisms collected from the lowest 2m outcrop, one of which (*Dendropoma*) grew at sea level {Stiros, S.C. and Pirazzoli, P., 1998. Late Quaternary coastal changes in the Gulf of Corinth, Greece: tectonics, earthquake, archaeology. Guidebook for the Gulf of Corinth Field Trip, Patras University, Greece, Patras, September 14-16, 1998}. Reef history has four phases: a) growth and lithification of reef; b) development of smooth-walled dissolution pipes and caves in the reef; c) colonisation of dissolution surfaces by Mn-Fe crusts (that may be bacterially formed), barnacles, serpulid worms, and rock-boring bivalves; and d) uplift to present position where much of the reef is eroded. Sea-level history after 11,500 years BP, when rising post-glacial sea level overtopped the Rio sill and returned the Gulf of Corinth to a marine environment, is reconstructed. Calculations of interplay between sea-level rise and tectonic uplift suggest that between 11,500 and 10,000 years BP sea level rose very quickly, associated with deglaciation at the close of the Younger Dryas, MWP-1B, at a maximum of 25.6 mm/year (broadly consistent with other studies), then slowed to ca. 4.4 mm/year until 6000 years BP when sea level was ca. 3 m below modern, after which sea level rose at ca. 0.5 mm/year to

- modern day. Tectonic uplift rate of maximum 3 mm/year, slower than sea level rise, means that thereef could not catch up to sea level until recent times.

- 22577 <SOURCE>Geological Society of London Special Publication 110 [McGuire W.J., Jones A.P. & Neuberg J. (eds): Volcano Instability on the Earth and other planets]: 153-167.</SOURCE>
- 22578 <ABSTRACT>The eastern flank of Mount Etna, Sicily has been recognized as being unstable, and three contrasting models have been proposed to account for this phenomenon, these being deep-seated spreading, shallow sliding and tectonic block movements. These models are examined by making reference to the rates and patterns of crustal movement along the eastern coastline of Sicily as determined from palaeoshoreline data. The south-eastern coastline of Sicily (Portopalo to Catania) provides no evidence of Holocene emergence. In contrast the volcanic coastline (Catania to Capo Schiso) and the northeastern shoreline (Taormina to Milazzo) display widespread evidence of coastal emergence. Radiocarbon dated remains indicate that both the volcano and

northeastern Sicily have been uplifted at a rate exceeding 1.5mm per annum during Holocene times, although more recent rates of uplift may have been greater. The pattern of uplift suggests that the northeastern coastline of Sicily, including the volcanic edifice, is apparently uplifting as a coherent unit, with superficial flank movements being superimposed on a regionally uplifting sub-volcanic basement. 22617 <ABSTRACT>In einem Kapitel der Arbeit wird ueber die Verwendung der roten Edelkoralle Corallium rubrum als Schutz- und Heilmittel berichtet. Ihr Wirkungsbereich ist sehr weit gespannt: Abwehr von Unheil (Blitz und Gewitter) und magischen Gefahren (boese Geister und boesen Blick), aber vor allem auch als Heilmittel bei verschiedensten Krankheiten, Epilepsie, Blutarmut. In dieser Funktion wurden vielfach Korallenaste an Halsketten getragen. So findet sich denn auch das Korallenastchen als Kinderamulett auf vielen Bildwerken des Spaetmittelalters dargestellt. Erste Nachrichten ueber das Tragen von Korallen als geheimnisvolles Abwehrmittel finden sich bereits bei Plinius d.A. (1. Jahrh. n. Chr), der dies von den Indern berichtet.</ABSTRACT>

22630 <ABSTRACT>The bibliography presented herewith includes data and references concerning fossil corals from Hungary; an exhaustive material published in geological and palaeontological works up to 1978. * The author has thought it advisable to give, in addition to conventional librarian data, lists of species as well. * On the one hand, these are indicative of the composition of the coral fauna, on the other hand, they are quick in being informative in the service of coral specialists, whenever they may need information on references, in Hungarian works, to single species. The lists of references have been grouped by geological ages. [original introductory part]</ABSTRACT>

22655 <SOURCE>Neues Jahrbuch fuer Geologie und Palaeontologie, Monatshefte 1995, 4: 235-247. [in German, with English abstract]</SOURCE>
22656 <ABSTRACT>The discovery of extended colonies of lithistid demosponges in the upper parts of the chert-bearing metamorphic platy limestones (Plattenkalk) in the Ida mountains on Crete island allows to conclude on their sedimentary depositional conditions. According to the spreading maximum of these types of silicosponges, the water depth under which they evolved has probably not exceeded 300-400m. We suggest a sedimentary regime settled on the margin of the carbonate platform at the transition to the slope. Further on the porifera do give a hint on the origin of at least parts of the large-scale chert deposits in the Plattenkalk Series of the external Hellenides.</ABSTRACT>

22771 <TITLE>Moosburg 4, die erste Kernbohrung durch den Malm unter der bayerischen Molasse.</TITLE>
22772 <SOURCE>Erlanger geologische Abhandlungen 123: 51-81. [in German, with English abstract]</SOURCE>
22773 <ABSTRACT>The drill hole Moosburg 4 intersected 985m of Tertiary and Cretaceous sediments followed by 134m of Purbeck-facies and the whole of the Malm with a thickness of 453m which was cored through-out. The Malm alpha and beta (Oxfordian, 67m thick) and the Malm gamma (Lower Kimmeridgian, 30-35m thick) underneath the Molasse could be compared bed by bed with the equivalent beds in the Franconian Alb and their identical development could be shown in detail. The individual marl beds of the Malm gamma in particular could be traced in similar thickness over a distance of 100km thus reflecting the very quiet depositional conditions on the southern Bavarian platform. The sponge limestones and dolomites of the Malm delta/epsilon (Middle/Upper Kimmeridgian) show a similar thicknesses in both areas of approximately 100m (here a leveling out of the relief by shallowing of the sea occurred at the boundary between Malm delta/epsilon). Two sections, one from Neuburg to Ampfing (fig. 9), the other from Anzing to Giftthal (fig. 10), however, show the variable facies developments in the platy limestones and the shallow water reefs of the Malm zeta (Tithonian). The microfacies proves an increasing constriction of the sea basin beginning at different points in time in the individual basins and reaching its climax in the evolution of the saline facies of the Purbeck. Without a sharp boundary the partly fossil-rich limestones of the Upper Malm pass into the fossil-free limestones and dolomites of the Purbeck with its characteristic dark tonflaser texture. Oolites, evaporitic laminites and solution breccias are interspersed throughout. In the Moosburg area a clear subdivision into a lower oolitic and an upper breccia bearing Purbeck is absent.</ABSTRACT>

22797 <TITLE>Diagenesis of the Veterlin reef complex (Male Karpaty Mts., western Carpathians): isotope geochemistry, cathodoluminescence, and fluid inclusion data.</TITLE>

- 22798 <SOURCE>Geologica carpathica 45, 4: 239-254.</SOURCE>
- 22799 <ABSTRACT>The void structures of the Veterlin Limestone are cemented by radiaxial fibrous calcite (RFC), which originated by transformation from the original metastable forms of carbonate. In the transmitted light, the cement of the remaining pores is shaped as blade and blocky pseudospar, while under cathodoluminescence it is structured as zonal luminescent scalenohedral calcite (SHC) and dull euhedral calcite (EHC). Nucleation of neomorphic pseudospar on crystals of predate high-Mg cement occurred in conditions of relatively shallow burial. Saddle dolomite is another product of the burial diagenesis. Seawater values of $\delta^{18}\text{O}$ (-1.2 to -4.5‰) and $\delta^{13}\text{C}$ (+1.5 to +4.1‰) or marine values influenced by mixing (values with a wider distribution of $\delta^{13}\text{C}$) are characteristic for isotopic composition of cements in the Veterlin Limestone. The final generation of cements (blocky pseudospar BPS) shows the influence of burial fluids with depletion of $\delta^{18}\text{O}$ (-6 to -9‰) and preservation of positive values of $\delta^{13}\text{C}$ (marine burial trend). The calculated isotopic temperatures from cements ranged between 18 to 60 °C. Homogenization temperatures of fluid inclusions are not consistent with crystallization temperatures of the burial cement, in accordance to their reequilibration under overheating and neomorphism. The Th of the fluid inclusions (155 - 350 °C) probably correspond to the peak-temperature conditions of the Veterlin Limestone, which is also partly the same as that obtained from the CAI of conodonts (110 - 200 °C). The presented diagenetic (cementation) model reflects more really our knowledge about the depositional conditions and also spatial distribution of facies in the Veterlin reef complex.</ABSTRACT>

22875 <TITLE>A new Cambrian sphinctozoan sponge from North America, its relationship to archaeocyaths and the nature of early sphinctozoans.</TITLE>
22876 <SOURCE>Geol. Mag. 127, 5: 435-443.</SOURCE>
22877 <ABSTRACT>A new early Cambrian sponge of sphinctozoan organization named Polythalamia americana nov. gen. et sp. is described from Nevada

and Alaska, USA. *P. americana* nov. gen. et sp. shows little resemblance to other Cambrian reported sphinctozoans, but is similar to late Palaeozoic to early Mesozoic forms from Europe and Asia, e.g. *Stylothalamia* and *Amblysiphonella*. The polyphyletic origin of sphinctozoans based upon spicule criteria from younger examples is therefore corroborated by the varied morphology and clearly widespread palaeogeographic distribution of Cambrian forms, which were hitherto recognized only from Australia. *P. americana* nov. gen. et sp. possesses a relatively small, globular multi-chambered calcareous skeleton, with thin but densely perforate walls and a central retrosiphonate, perforate spongocoel. The skeleton is composed of an irregular microstructure of unknown, but probable calcitic, original mineralogy. There are no spicules or primary internal structures, but secondary vesicular filling tissue is present. The pore organization, however, is directly comparable to archaeocyaths, e.g. *Coscinocyathines*, and this character is taken to be the only synapomorphy available for taxonomic and phylogenetic purposes. Indeed, *P. americana* nov. gen. et sp. is closely associated with a diverse archaeocyath assemblage and draws attention to morphological similarities between some archaeocyaths and sphinctozoans, thus questioning the criteria at present used to distinguish between these groups. Accordingly, a list of nomenclatural synonymies is given to aid comparison. *Coscinocyathine* archaeocyaths possess chambered juvenile stages and *P. americana* nov. gen. et sp. is suggested to represent an aspiculate lineage of sphinctozoan grade which may be derived from forms such as *Clathricoscinus* by neoteny. It appears that at least three clades of sphinctozoan-grade calcified sponges were present by end of early Cambrian time and their occurrence in association with island arcs of the palaeopacific rim is confirmed.

22901 <TITLE>Review of some species of *Favistina*, *Nyctopora* and *Calapoecia* (Ordovician corals from North America).</TITLE>

22902 <SOURCE>Geological Magazine 113: 457-467.</SOURCE>

22903 <ABSTRACT>Material from the H.A. Nicholson's collection, University of Aberdeen, provides information on three of Nicholson's species. Syntypes of *Favistina calicina* are described and the lectotype designated. Topotypes of *Nyctopora billingsii* are compared with an earlier description of the type thin sections. *Columnopora cribriformis* is considered synonymous with *Calapoecia huronensis* Billings, itself a poorly understood species; redescription of the type

of the latter species shows it to be separate from *C. canadensis* Billings. *Calapoecia ungava* Cox is reinterpreted with a lectotype designated, and Nicholson's material is placed with this species. All specimens are from eastern North America and of Upper Ordovician age excluding the Middle Ordovician *N. billingsii* and *G. canadensis*.
